Extensive burns form a fourth group of cases seen in traumatic work. Here physical therapy can do splendid work in all phases of the condition. The most satisfactory treatment that I have seen for the treatment of the local condition has been the application of 2½% to 5% tannic acid applied immediately and until coagulation has occurred over the traumatized area. Radiant heat, constantly applied, not only hastens the action of the tannic acid but materially lessens pain, keeping the part at a constant temperature. In the last stages, when epithelialization is taking place, ultra-violet light has been shown to be a definite stimulant to this process.

A fifth group of traumatic cases is comprised of those low back injuries which form such a formidable problem to anyone seeing traumatic cases. These cases constitute one of the most important disabling factors in traumatic and compensation work. They are the cases in which, when appropriately applied, physical therapy can do so much and conversely they are those which,

with misdirected physical therapy, can be continued so long disabled.

As in all medical or surgical conditions the indications for treatment depend entirely upon what is the matter. An individual reports to the doctor with a pain in his back following an injury. The most searching clinical examination is not sufficient for diagnosis. It is my opinion that no back injury should receive physical therapy without antero-posterior, stereoscopic and lateral view x-rays. We have all seen the case of pain in the back treated with baking and massage for an indefinite period and, when no improvement occurs, x-rays are taken showing a fracture of the lamina, transverse process or some other bony condition. Clinical examination will elicit much but it is frequently impossible to accurately rule out bone pathology without x-rays. When an injury occurs to the lower part of the back we must form an opinion as to what this pathological condition is. Fractures of the spinous processes, articular processes, bodies or lamina, luxations, hematomas, tearing of the lumbar fascia sprains, congenital abnormalities, postural abnormalities, latent disease such as tuberculosis or chronic arthritis, all of these are factors which must be considered. In the soft tissue group physical therapy can assist very much but in the injuries to bone or in latent disease physical therapy cannot be substituted for other measures. To do so can only result in failure and in the disrepute of physical therapy. In those cases of bone injury following the bony repair, physical therapy may be indicated in the restoration of motion and, as such, has a definite place. I would remind you that, in selected cases, there is a place for manipulation and there is also a usefulness for the combination of physical therapy plus adequate support, whether it be brace, removable corset or belt.

Injuries to the peripheral nerves constitute a sixth group. Here again accuracy in diagnosis is essential. The neurologist, the surgeon and the physiotherapist must work in conjunction. Accurate diagnosis must predicate the type of treatment to be instituted. Prior to operation much information can be gained from electrical investigation of musculonerve reactions. Following operative repair the position necessary for the maintenance of nerve contact may preclude the general use of physical therapy but it is rarely that all physiotherapeutic measures must be postponed because of this. To illustrate an ulnar nerve which has been divided with loss of substance may frequently have to be transplanted to the anterior surface of the elbow before its ends can be brought into continuity. This means that the elbow must be kept flexed during the first six weeks so that physical therapy cannot do all the work that it might while, at the same time it is of the utmost importance that the elbow be maintained flexed until healing has occurred at the site

of suture. With cooperation the physiotherapist can usually institute measures keeping the part in this flexed position and at the same time carry out the measures which will aid in nerve regeneration and also maintain the nutrition of the parts supplied by that nerve in the hand. Heat, diathermy, faradism and exercises to those active groups will do much in assisting regeneration.

Sprains and strains constitute a large group of the traumatics. A sprain is a tearing of a ligament while a strain is a stretching of this tissue. Support, elevation for the first twenty-four or forty-eight hours followed by active physical therapy and exercise with care to prevent further insult by re-stretching or re-straining the traumatized ligament will definitely lessen the period of disability. In an ankle joint the wedging of the heel of a boot will frequently prevent the re-straining of this ligament while it is healing, while the active physical therapy will hasten the reparative process by speeding up the local metabolism. The commonly employed strapping of injuries of this sort for weeks before physical therapy is instituted is to be decried.

Bursitis, myositis, synovitis and tenosynovitis are other traumatic conditions amenable to properly applied physiotherapeutic measures which space alone prevents me from giving due consideration. The adequate treatment of any of these subjects would require a paper in itself.

To sum up, Physical Therapy in traumatic conditions is indicated:

1. In fractures and dislocations.
 - (a) Early to relieve pain and spasm.
 - (b) To promote absorption of extravasated products.
 - (c) To improve muscle tone and range of motion in joints.
 - (d) In later stages to hasten calcification on decalcification.
2. In infection and the results of infection.
To hasten absorption of by-products of inflammation, improve motion in joints soften scar tissue and lessen fibrosis.

3. In burns for hastening local coagulation, lessening pain and stimulating granulation and epithelialization.
4. In back injuries.
To promote absorption of extravasated blood and lymph, thereby lessening pain, improving muscle tone and activating joint motion.
5. In peripheral nerve injuries.
To maintain nutrition, stimulate regeneration and improve muscle tone and function.
6. In sprains and strains.
Lessening blood and lymph stasis, promoting early active motion.
7. In bursitis, myositis, synovitis and tenosynovitis.
For the removal of waste products, sedation and promoting early function.

Physiotherapy is contraindicated:

1. Where other medical or surgical procedure has proven superior.
2. After the patient can do what the therapeutic measure is aimed at helping him perform.
3. Before an adequate examination, both clinical and laboratory, has revealed the pathology present.

An experienced doctor once said: "Do not permit yourself the luxury of an hypothesis to save yourself the drudgery of an observation." If we were to carry this thought into Physical Therapy, with more exacting observations on the effectiveness of each modality upon traumatized tissue, I believe that we would be less apt to employ empirically modalities which might be of the utmost usefulness in conditions other than those for which we now use them.

CONSERVATIVE SURGICAL CONSIDERATIONS IN THE TREATMENT OF CANCER OF THE BREAST*

By WILLIAM L. CORCORAN, M.D., NEW YORK, N. Y.

CARCINOMA of the breast continues to be one of the foremost problems in the field of malignancy. This contribution is based on a study of cases encountered in hospital service and includes a few conservative points in treatment. The form of treatment described here-

in represents an endeavor to avoid some of the most obstinate and serious manifestations following radical surgery of the breast.

Surgery is recognized as having achieved a certain degree of prestige in combating malignancy and the consensus of opinion still prevails among many that surgery alone is the only effective method in the treatment of cancer. However,

* Read in part before the Section of Cancer at the annual meeting of the Pan American Medical Association, Mexico City, July 27, 1931.

radium has also contributed its measure to the success of certain cases and high voltage x-ray with the more recent advances in filtration, renders the contribution of value as a pre- and post-operative form of therapy. The value of x-ray and radium radiation as associate forms of therapy, in conjunction with conservative mastectomy in the early and advanced cases of breast involvement, will also be considered.

It is not the purpose of this paper to bring into disrepute the radical operation for carcinoma of the breast as devised by Halsted, Meyer, Cheyne, Handley, Kocher, *et al*. This type of operation has its specific indications but on the other hand, it seems wholly unscientific that in every case of breast cancer the same orthodox procedure should be adopted.

These observations are based on custodial cancer patients who have been subjected to radical surgery and present in their late post operative careers serious complications such as persistent fibrous edema of the upper extremity with traumatic neuritis, painful thoracic scar formation, loss of thoracic soft tissue protection, recurrences and varying degrees of metastases. The very fact that the disease recurs in the scar area indicates that extensive surgical resection at times does fail in its purpose by disseminating malignant cells during manipulation. In many instances, the fibrous edema is the exciting cause of death independent of the disease itself. A post-mortem study of this condition proves it to be due to a lack of venous drainage resulting from traumatic scar tissue formation.

Many authors advise complete ablation of the axillary and clavicular glands whether palpable or not as a prophylactic measure against metastasis. If glands are palpable, metastasis is usually present and the prognosis is definitely limited. If no glands are demonstrable why give rise to a potential source of complication by stirring up a sensitive axillary anatomy? The same attitude exists in regard to the routine removal of the pectoral muscles. The anatomical factor is generally overlooked that in many instances two-thirds of the breast are attached to the serratus and external oblique muscles and the vascular and lymphatic associations in these structures are as prominent as those permeating the pectorals.

Balfour,¹ in his masterly paper on cancer of the stomach, in which he states the mortality rate should be less than 10%, and where the anatomical and physiological factors of the lymphatic glandular system presents a similar problem as in cancer of the breast, points out two important facts regarding enlarged lymph nodes, namely (1) enlargement does not necessarily mean involvement by cancer, and (2) a patient may be cured even if all involved lymph nodes

are not removed. He corroborates the foregoing points by further stating "I believe it to be a possibility that in cancer in any situation, removal of the primary growth and of the immediately adjacent lymphatic structures may bring about permanent cure even if involved lymph nodes are left, the remaining nodes in such cases act as a sufficient barrier to further dissemination of the disease. It is, therefore, occasionally good practice to disregard involvement of lymph nodes if the primary growth can be removed, and to remove the adjacent lymphatic structures as completely as possible."

By the term "conservative mastectomy" is meant a surgical process which varies from a limited radical procedure, without manipulation within the axilla, to the simple removal of the breast tissue proper from its attachments to the thoracic wall. By "limited radical procedure" is meant the absolute avoidance of any surgical manipulation within the axilla and the removal of the pectoralis major when said structure is involved, and even of the pectoralis minor when the latter is definitely involved.

The conservative amputation should be performed with the following surgical factors in mind. The skin incision should be so planned that there is a wide margin of apparently healthy tissue surrounding the tumor mass, and at the same time bearing in mind the necessity of leaving sufficient normal tissue so that absolute approximation of the wound edges can be secured. The resection should be done so that the tumor and surrounding tissue is removed in such a manner that the pectoral fascia be included. Careful handling of the tissue following resection is essential, all bleeding vessels should be clamped and ligated immediately upon being severed, and counter drainage, independent of the line of incision, should always be established.

The employment of conservative mastectomy in localized ulcerating breast lesions is recommended, even in the presence of metastasis, in order to avoid a progressive phagedenic process from advancing, oftentimes leading to skin metastasis. This is suggested as a purely palliative measure for the comfort of those patients, some of whom may have a period of years to live.

Cancer of the breast is one of those conditions in which it is most difficult to determine the prognosis. The same type of tumor involvement as regards size, location and pathology in two different individuals will assume such different courses that no surgeon would attempt to predict with any degree of accuracy the result of operation, liability to metastasis or recurrence. It is encouraging and interesting to note that patients over fifty years of age possess some unknown defensive factor in the body mechanism which appears to combat the virulence of the disease, even in the presence of advanced metastasis.

¹ Balfour, Donald C. Curability of Cancer of the Stomach. *Surg Gyn and Obst* 54 315 Feb 15, 1932

To give a plausible explanation as to why cancer of the breast offers so unfavorable a prognosis, it is necessary to consider the anatomy in order to point out the diversity and freedom of paths of dissemination. Metastatic cells are transported by lymph and blood vessels and by an insidious process known as permeation. It has been stated that aside from cancer of the pylorus, cancer of the breast gives rise to the widest form of metastasis. This is due to its complex and extensive anatomical structure, further influenced by its physiological processes.

A review of the anatomy shows that the vascular system of the breast is made up of branches from the internal mammary, intercostal and axillary arterial systems. The lymphatics, which are also of great moment to the surgeon, consist of a superficial or subcutaneous plexus which cover the periphery and a dense network of deep lymphatic channels traveling through all parts of the glandular tissue. This deep system connects with the lymphatic trunks of both the deep fascia of the chest and of the abdominal wall with an extensive anastomosis between these two systems as well. The lateral portion of the breast is drained by trunks which run along the outer border of the pectoral muscles and are drained by nodes within the axilla, and by extension communicate with the sub- and supra-clavicular nodes. The mesial portion of the breast is drained by deep lymphatics, which perforate the intercostal spaces, to be drained by the nodes in the anterior mediastinum. A connection of lymphatics of both breasts across the sternum at times may give rise to dissemination to the opposite side.

Stress is laid on the necessity of roentgen investigation in all cases of breast involvement no matter how innocent the local involvement may appear, as metastasis to the lungs and skeletal system may be present and exceed in activity and scope beyond the primary condition. By the utilization of this important diagnostic feature, the degree of dissemination can be determined so that radical surgery can be intelligently selected over conservative, as suggested in the classification soon to follow. The following case of a localized tumor formation, without glandular evidence, in a woman of 32 years of age is an interesting example of its value in diagnosis. While ascending the stairs at the clinic, this woman sprained her ankle and an x -ray was taken to determine the trauma. Examination of the radiograph revealed a bony metastasis and subsequent investigation showed a generalized bony involvement.

The question of biopsy in cases of breast involvement might well be limited to those cases where decided diagnostic factors are absent. Usually the advanced or moderately advanced cases require no biopsy, as pathologic classifica-

tion does not indicate radio-sensitivity or individual susceptibility to virulence. In such cases it is better to consider surgical removal and submit the entire breast to pathological examination rather than risk dissemination by localized enucleation. However, no matter how innocent a tumor may appear on gross appearance, a microscopical study should always be made to determine its pathology. A small localized mass can very well be enucleated without injury to neighboring tissue.

High Voltage X-ray and Radium: Before entering upon treatment, it is proper to consider the value of x -rays and radium, as associate forms of therapy, and their methods of application. The success of irradiation is based on the biological effects produced when the tissues are subjected to a change in intra-cellular energy. The destruction of a cell is determined by the relationship of that energy and the sensitivity of the cell. The degree of sensitivity in a group of cells making up a tumor oftentimes is variable, and depending on this variability a tumor may demonstrate itself as being radio-sensitive or radio-resistant. The defiance of the radio-resistant type of cell may equal or excel the resistance found in the adjacent or surrounding normal tissue cells. This factor presents a situation whereby certain high resistant cells may give rise to recurrence or be the source of metastasis. The cells of tissues to be influenced are more sensitive to the radiation absorbed by them than those of the neighboring healthy tissues. The element of resistance to radiation may be combated in some degree by a specialized technic in application and division of dosage. In any event, the higher the sensitivity the more malignant the character of the cell, and such being the case the virulent elements are more easily destroyed and recurrences and metastasis checked by subsequent irradiation. Marked radio-sensitivity is no criterion for the ultimate success of the cure.

X-ray Therapy: In x -radiation the treatment should be planned so that the tumor mass will receive a desired dosage and the adjacent normal tissues are not subjected to injury. For this purpose fractional exposures are employed, that is, the application of rays through several portals at different intervals in such a way that no one area of skin receives more than a full erythema dose. Target distance, filtration and time of exposure, all depending on the site of the pathology in relation to the surface to be attacked, are factors to be taken into consideration.

At times tumors show regression to x -radiation and occasionally they are converted into freely movable and limited masses, thus changing their condition from a non-operative type of growth into an operative one.

A study of the palliation problem reveals that high-voltage x -ray is of marked value in the

treatment of pulmonary and skeletal metastases, is well as in pelvic involvement. The pain and disability resulting from bone metastasis following surgical removal of the breast may often be relieved and the life of the patient greatly prolonged. Its use is recognized by many as a pre- and post-operative form of treatment in cases of glandular and soft tissue involvement.

Radium Therapy. Radium in cancer of the breast may be applied in the form of surface application by way of the mould or interstitially in the form of needles of the element or of radon. In the case of a tumor formation within the breast, where radium therapy may be considered, interstitial treatment with needles is the method of choice. Needles may be conveniently inserted into metastatic glands within the axilla, clavicular regions and close to the pectoral muscles. These processes may also be treated with mould applications. Skin recurrences are treated with wax moulds and at times with the insertion of gold seeds of radon. However, mould applications are more desirable.

In radium therapy the different types of rays and the variations within each type must be considered. Practical requirements are met by filtration. The radiation which acts upon normal as well as pathologic tissues must also be considered.

Failla,² of the Memorial Hospital of New York, states "The effective utilization of radium in all cases of carcinoma should be based on the following factors:

- 1 The amount of radium
- 2 Duration of irradiation
- 3 Filtration
- 4 Distribution
- 5 Spacing
- 6 Geometrical configuration of tissues
- 7 Absorbing power of tissues for the particular irradiation which reaches points therein."

Treatment. The chief form of therapy in the post-operative cases is palliative. An endeavor is made in this clinical study to employ a form of research, based not only on the workings in the pathology laboratory and the suggestions in the literature, but one guided by observations of cases under palliative treatment. The scientific and practical contributions at our disposal are the result of studies of the various cancer institutes throughout the country, notably those which are adhering closely to the outlines suggested by the American College of Surgeons as a fostering unit. These institutions have patterned their working progress after careful group study both here and abroad and are enabling us to give practical consideration to the associate use of radium and high voltage x-ray along with sound surgical principles.

For the clarification of treatment a therapeutic

classification of cases, as outlined below, is respectfully suggested. Such a classification seems feasible in order that a more favorable post-operative status for the patient will possibly be established than that heretofore obtained by radical surgery. Each case should be carefully studied and taken according to the duration of the disease, size and location of the tumor, defensive factors, laboratory findings and the presence or absence of lung, skeletal and soft tissue metastases and palpable glands.

Class I

- 1 Localized tumor formation
- 2 No palpable glands in axilla
- 3 No palpable glands in sub- or supra-clavicular regions
- 4 Roentgen studies negative for metastasis to lungs or skeletal system

Treatment

- a A course of pre-operative high voltage x-ray to breast, axilla and clavicular regions
- b *Conservative mastectomy*
- c A course of post-operative high voltage x-ray
- d Periodic roentgen investigation

Class II

- 1 Breast tumor
- 2 Palpable glands in axilla and clavicular regions
- 3 Roentgen examination positive for skeletal or lung metastasis or both
- 4 No suggestion of skin metastasis

Treatment

- a A course of pre-operative high-voltage x-ray
- b *Conservative mastectomy*
- c Radium needles inserted in axillary, clavicular glands and beneath pectoral muscles
- d Subsequent repeated courses of high-voltage x-ray for metastasis, as indicated by periodic roentgen investigation

Class III

- 1 Breast tumor
- 2 Palpable glands in axilla
- 3 Palpable glands in clavicular regions
- 4 Roentgen investigation negative for metastasis
- 5 No suggestion of skin metastasis
- 6 Clinical and laboratory findings otherwise negative

Treatment

- a A course of pre-operative high voltage x-ray
- b *Radical mastectomy*
- c A course of post-operative high-voltage x-ray, to be repeated during follow-up treatment, as indicated by periodic roentgen investigation

Class IV

- 1 Ulcerative tumor involvement

²Clark, John G. Norris, Charles C., Failla Gioacchino. Radium in Gynecology, J. B. Lippincott Co., p. 86

2. Palpable glands in axilla.
3. Palpable glands in sub- or supra-clavicular regions.
4. Roentgen investigation positive for lung, skeletal metastasis or both.
5. No evidence of skin metastasis.

Treatment.

- a. A course of pre-operative high-voltage *x*-ray.
- b. *Conservative mastectomy.*
- c. Subsequent courses of high-voltage *x*-ray for palliation, as indicated by periodic roentgen investigation.

COMMENT

The indications for radical mastectomy of breast cancer depend primarily on the extent of involvement of glandular metastasis within the axillary or clavicular regions and on the absence of skeletal or lung metastasis.

In the employment of high-voltage *x*-ray therapy the contraindications for such treatment must constantly be borne in mind. The presence of telangiectasis and other complications must be noted and a complete blood count, prior to and

between courses should be studied. The history of any previous treatments should always be recorded. Radiation after operation should not be given until complete healing has occurred. An operation after a preceding radiation should not be performed until two or three weeks after such treatment.

SUMMARY

1. The value of conservative mastectomy in conjunction with high-voltage *x*-ray and radium therapy, over radical operation, in early and advanced cases of breast involvement is considered. However, no attempt is made to disregard the value of radical operation when certain specific diagnostic endeavors have been taken into consideration prior to operation.

2. A classification and outline for treatment are suggested in order that a more favorable post-operative status might possibly be established than that heretofore obtained from the usual surgical method of attack in all cases of breast cancer.

3. The importance of roentgen investigation in all cases of breast cancer is stressed as a guide for the type of operation to be selected.

THE ROLE OF VITAMINS AND INFECTION IN PEPTIC ULCER

By EDWARD F. HARTUNG, M.D., NEW YORK, N. Y.

From the Gastro Intestinal Clinic, Third Medical Division, Bellevue Hospital, New York.

IF vitamin deficiency and infection play a part in the etiology of peptic ulcer, the removal of these factors should aid in the recovery. Patients treated with these factors in mind should do better than others not so treated. This paper records the effort to verify by therapeutic tests these two current theories as to the etiology of peptic ulcer. There has been a great deal of discussion concerning its causes ever since the first observations were made over 300 years ago. It cannot be stated in such a simple way as some authors would lead us to believe. Thus, to say¹ that the essential causes of peptic ulcer are now well known, that they are a combination of gastric juice, injury to the stomach mucosa, and factors which lower the general resistance of the patient, is to merely put in words our lack of knowledge on the subject. Also such causes as heredity, autonomic instability, worry, emotion, hard work, "psychic load," neurasthenia, unhygienic conditions, hereditary abnormalities in the circulation of the stomach, are all suggestive but only slightly helpful in therapy. It is naturally an important subject, because when we know the cause we shall probably be quite near an adequate treatment, and everyone who has much experience with ulcer realizes that our present treatment is extremely unsatisfactory.

Surgeons differ with medical men, and worst of all, medical men differ among themselves.

Beyond the factors of infection and vitamin deficiency, very little has been added to the medical therapy since Abercrombie's² day. This wise Scot put in a few words in 1824, the treatment we rely upon today. Subsequent workers have merely methodized and scheduled his treatment. He said "the food should be of the mildest kind, and in very small quantities, with abstinence from all stimuli, and from bodily exertion. Mercury in small quantities seems to be useful in such cases, in others lime water and the oxide of bismuth."

The Infection Theory: Of the many theories developed to explain ulcer, probably the most persistent one is that ulcer is due to infection and is especially the result of focal infection. It is not new. Long before Pasteur, the early writers on ulcer, Broussais (1823) Abercrombie (1824) and J. Cruveilhier³ (1830) remarked on the inflammatory appearance of ulcer. Böttcher⁴ (1874) shortly after Pasteur's work, demonstrated microorganisms in ulcers. Foreshadowing Rosenau, Letulle⁵ (1888) injected "Cultures Microbienes" intravenously in animals and produced gastric lesions. Following this, many workers performed similar experiments and made confirmatory ob-

servations, notably Fabre, Wurts, Vidal, and Gordon⁶. Not much attention was paid to the idea, however, until Rosenau's⁷ work was published in 1913. This work is now well known. He demonstrated in animals that certain streptococci circulating through the blood stream had a special affinity for the gastric mucosa and caused gastric lesions. Later (1915) he isolated streptococci in pure culture from many ulcers. Haden⁸ (1925) and Meisser⁹ (1925) supported Rosenau's work by obtaining ulceration from streptococci isolated from infected teeth, and in 1928 Nickel and Hufford¹⁰ added support to the idea using streptococci from other foci as well, such as tonsils, prostate and cervix. Most recently E. W. Saunders¹¹ (1930) isolated a non-hemolytic streptococcus from resected ulcers. Agglutination reactions, using the serum of patients with peptic ulcer and this particular streptococcus, showed, according to Saunders, that ulcer is caused by, or at least always associated with a specific type of streptococcus.

Clinically, also, other factors make one suspect the relationship of ulcer with focal infection. Many have observed that intercurrent colds, acutely abscessed teeth, or infections of any kind will make ulcer pain worse. Also, the extraction of infected teeth and diseased tonsils will aggravate the disease. The situation is analogous to that in arthritis, where focal infection has a very substantial basis in fact.

Certainly it is true that focal infection as a factor in ulcer has received at least tentative reception among medical men. Most physicians now remove focal infection, if found, in association with their usual Sippy regime, and feel that the procedure is somehow of value.

Vitamins in Peptic Ulcer: Years ago, (1904) Deeks¹² contended that a high carbohydrate diet produced "gastric irritation." This is an interesting article far ahead of the times. At that time the vitamin itself was not an actual conception. More recently, McCarrison¹³ reiterated this statement in the light of our modern knowledge of vitamins. He was impressed with the rarity of gastric and duodenal ulcers in the natives of the Himalaya Mountains, and laid this to the fact that they used exclusively the so-called natural foods, such as milk, eggs, grains, fruits, and leafy vegetables. In 3600 major operations he did not see one case of ulcer, appendicitis, or mucous colitis. He also tried to prove experimentally that monkeys fed on a deficient diet would develop peptic ulcer. Those monkeys which received a sterilized carbohydrate diet developed ulcer. The emphasis was laid on Vitamins B and C as the most important factor in protecting the gastro-intestinal tract from infection. The role of food in the causes of many diseases, according to some authors, involves increased susceptibility to infection due to lowered resistance caused by faulty diet. The actual excess of carbohydrates,

per se, is also supposed to be a contributory factor in ulcer. Is the apparent increased incidence of peptic ulcer due to the fact that we are yearly consuming more carbohydrates? We in America have been referred to as the sugar saturated nation. This tendency is a definite trend of the times. "The consumption of sugar has increased 500% in the past 60 years." The peak of sugar consumption in United States was reached in 1926 when 109.3 pounds were used per capita. On this basis it was estimated that nearly one-fifth of the requirement of food fuel in this country was supplied by pure refined sugar.¹⁴ Whether it is a fact that ulcer patients belong to a group that over-indulge in carbohydrates, and thereby lack sufficient vitamins, as stated by Harris¹⁵, is an observation that I have not been able to verify. However, if all the above is correct, we should expect the administration of a low carbohydrate diet and large quantities of Vitamin B and C to act advantageously in peptic ulcer. This is one of the points we tried to prove in our series of ulcer patients. It is also interesting to note that the usual Sippy diet, which is the most widely used form of treatment, is quite deficient in Vitamin B and C. On the other hand there are many observations which lead one to doubt the etiologic relationship of vitamins and ulcer. During the World War there were serious outbreaks in the Civil and Military population, of scurvy osteomalacia and other nutritional diseases, and yet the incidence of peptic ulcer was not markedly increased.

Method: At the gastro-enterological clinic of the fourth Medical and Surgical Division, we have endeavored to put to test, in the cure of ulcer, the effect of a high vitamin diet together with the removal or treatment of focal infection. We purposely associated the two factors simultaneously in therapy because of their reputed dependence. The treatment consisted of (1) A normal diet without interval feedings. (2) The assured inclusion of all known vitamins. (3) The removal or treatment of focal infection. (4) Vaccine therapy (non-specific). One would expect, if ulcer were caused by these factors that treatment directed along these lines would cure the condition, or at least give better results than where these were ignored. This result would especially be expected if the disease were due to vitamin deficiency, where one might expect such rapid restitution of normal function and structure as in rickets, scurvy, and other nutritional diseases. We report here sixty patients with peptic ulcer treated in this way during the past two years, and followed, in all, over three years. Every patient had a complete dental examination and dental X-ray. Tonsils were carefully examined and a history of tonsil infection elicited. Other foci were sought, especially gall bladder disease and infections of the genito urinary tract. These latter factors were not frequently met. Figures

on the incidence of gall bladder disease in association with peptic ulcer are not commonly published. Some surgeons feel a mild cholecystitis is common. When found it is probably an associated pathology rather than a causal focus of infection, just as in the case of chronic pancreatitis. Together with this treatment we gave our patients non-specific protein injections. These consisted of stock vaccines made from streptococcus viridans and streptococcus hemolyticus with some B. Coli and staphylococci, the idea being not to seek for a specific immunity but for a non-specific action. It was considered that such injections stimulate the immunological protective mechanism of the body. These injections were given once a week sub-cutaneously, a reaction being avoided. Holler in 1922¹⁶ was apparently the first to apply protein therapy to the treatment of peptic ulcer. He used milk and various vaccines. Pribram in 1922¹⁷ and later L. Martin¹⁸ (1929) reported excellent improvement in the administration of the various non-specific proteins. Following these the method has been in frequent use.

The diet outlined for the patients in this series consisted of three meals a day without any intermediate feedings. Patients were immediately placed on a well-balanced diet such as should maintain excellent health in an average human being. Sippy regime and ulcer regimes of all kinds were sedulously avoided. Indiscreet combinations, and difficult and grossly coarse foods were restricted. Patients were instructed, however, to include in the daily diet at least one raw fruit, one raw vegetable, two cooked fruits, two cooked leafy vegetables, and a moderate portion of meat, six butter balls a day, whole wheat bread, and some kind of unrefined cereal. In addition to that, in order to be absolutely sure that all the vitamins were in excess, the patient was instructed to take daily two ounces of tomato juice, two teaspoonfuls of cod liver oil, together with either yeast, Bemax, or Vitavose daily. In addition, our patients received ultra-violet radiation over the abdomen, two or three times a week. This diet without question is rich in all the known vitamins. The reception of this food (especially the factor of three daily meals instead of interval feedings) was quite satisfactory. It is traditionally essential in ulcer patients that they receive interval feedings and bland foods. Most of our patients, however, received symptomatic relief at least at first under this regime. A few, however, required interval feedings of milk and cream in order to get relief from pain. All medication was sedulously avoided.

Findings Before Treatment: The sixty cases were under observation over three years. There were 82% males and 18% females. All of these patients received complete laboratory investigation. The tests included Ewald test meal, chemical blood analysis, urine, complete blood count,

Wassermann, stool examination and so forth. There was nothing especially of note in these laboratory reports, the findings being about as normal as in any group of cases. Complete physical examinations were done with the special idea of seeking out all possible foci of infection.

A great deal of dental pathology was found. Caries were noted but not studied statistically. Only nineteen of the sixty patients showed no apical infection and no pyorrhea on examination. 68% showed gross dental infection and required removal of one or more teeth and drainage of pyorrheal pockets. This incidence of infection is rather high, but here we are dealing with a specially low economic group, which fact probably accounts for the high incidence. The general impression is that teeth are a far more potent factor in peptic ulcer than are tonsils. This is analogous to the situation in arthritis, where we consider the tonsils as a factor in the younger group and teeth as a factor in the older group (over 35). Four tonsillectomies were required. The infrequent importance of the sinuses is similar to the situation in arthritis, but in our series all real sinus trouble received special treatment. There was revealed a high percentage of membranous thickening, especially in the antra, but no real suppurative processes, either acute or chronic.

All patients were subjected to thorough gastrointestinal X-ray examinations at the beginning of the treatment, and regularly thereafter at intervals of three months in order that the X-ray as well as the clinical findings could be followed. It is a common observation in ulcer patients that their symptoms are relieved, as a matter of fact they become symptom-free, and yet the X-ray shows no improvement in the ulcer. Hence the importance of frequent X-rays. 11% were gastric, 87% duodenal, and 2% marginal. 20% had been previously operated upon.

Results of Treatment: The question was: does a treatment, which has for its object the removal of focal infection and the institution of a high vitamin diet, in itself cure ulcer, or aid in its cure? To actually know this, one must compare our results with those obtained by the usual Sippy method. We have endeavored to collect a few of the published reports on the results of ambulatory Sippy treatment. (See appended chart.) With this information as a basis, we were able to note whether a regime paying strict attention to focal infections and vitamins were superior to the usual Sippy regime. In our series there was symptomatic relief, practically complete, in 58% of the cases. In addition to the 58%, 12% of the cases showed moderate improvement, and 10% slight improvement. In 20% there was complete failure. Ten percent of the patients required operative interference during the treatment and had gastric surgery. Six percent perforated and 8% had hemorrhage during the treatment. Most of the latter, however, recovered and made good

RESULTS OF AMBULATORY SIPPY TREATMENT IN PEPTIC ULCER.

Reporter	Number of Cases	Type of Ulcer	Time Followed	Symptomatic Results	Hemorrhage	Perforation
Beams, A. J. <i>Ohio State Med. J.</i> xxiv:21, 1928	121	Gastric and Duodenal	6 months to 5 years	92.2% remain well 9 recurrences 6 failures		1 case
Carter, H. S. <i>Bull. N. Y. Academy Med.</i> ii:580, 1926	From Series of 10,000 cases treated all methods	Gastric and Duodenal	2 years or more	32% cured		
White, F. W. <i>Boston Med. & Surg. Jour.</i> xcv:983, Nov. 18, 1926	206	Gastric 54 and Duodenal 152	3 to 5 years	Well Better No Better	Duodenal 57% Gastric 30% Duodenal 21% Gastric 24% Duodenal 4% Gastric —	
Gatewood, W. C. <i>Northwest Med.</i> xxvii:580, Dec., 1928	261	Gastric and Duodenal	2 years	Symptom Free Arrested	48.7% 13.4%	
Blackford & Bowers, J. M. <i>Am. J. Med. Sciences</i> clxxii:51-58, Jan., 1929	66	Gastric 6 and Duodenal 60	2 to 10 years	58% "Satisfactory" 13% Improved		5 cases
Nisbet, W. O. <i>Southern Med. & Surg.</i> 89:155-159, March, 1927	24	Gastric 1 and Duodenal 23	2 to 5 years	41%		

progress. The X-ray findings are of interest. Despite the fact that there was a considerable percentage of patients relieved, only 14% showed negative X-rays. There was another 24% which showed negative X-rays during treatment but subsequently the ulcer returned visible to X-ray examination. It merely bears out what is already known but not fully appreciated, that the patient may be free of symptoms and yet have a persistent ulcer. Such ulcers, even when symptom free are apt to bleed or to perforate suddenly, much to the surprise of the physician and patient. It is also interesting to note that all our excellent results were obtained with duodenal ulcers.

Conclusion

The relation of focal infection and vitamin deficiency to peptic ulcer is problematical, at best. Certainly the indiscriminate removal of teeth and tonsils is to be deplored. Such a practice is not warranted by the benefits seen to accrue. While on general principles the removal of real, proven focal infection and the administration of a balanced vitamin diet is indicated, these measures are probably no more valuable in peptic ulcer than in any other constitutional disease. Peptic ulcer is a disorder whose real cause is yet to be demonstrated.

CERTAIN EDUCATIONAL, PROFESSIONAL AND CIVIC PHASES OF CLINICAL SPECIALIZATION*

By GEORGE H. MEEKER, Sc.D., LL.D., PHILADELPHIA, PA.

Dean, Graduate School of Medicine, University of Pennsylvania

MR. CHAIRMAN, Distinguished Guests, Honored Hosts, Ladies and Gentlemen: On this occasion, the actual dinner, albeit Lucullan, is but a pleasurable incident: the social delights of such a communion of gracious women and potent, and eloquent men are delightful, inspiring, items: but they are only the fine interlude in an absorbing, continuing, human-interest drama which began long ago; and which in its next act nears one climax.

The central figure of this drama is man with his age-old burden of physical ills. Its action centers around his waxing hope that in health he yet may be conceived and born; that in health he may mature; and that through maturity and to his sunset he may progress and wane in bodily peace. It is meet that, in this interlude, we discuss this hope of man.

In this day, his hope is justified: not in its fulness; but to the degree that a vast amount of human suffering now endured is, in fact, unnecessary. Mankind as a whole does not know this fact, so vital to his happiness. Indeed it is known only to enlightened ones.

The justification of man's hope is to be found in the potential riches of the sum total of today's medical knowledge and skill. The pith of the matter is to make these riches kinetic in a broad and efficient sense, rather than in the prevailing relatively narrow and inefficient sense—to cause such riches, now enjoyed by a minority, to become enjoyed by a great majority—by all, indeed, who shall, intelligently, reach forth for them.

This gathering is essentially one of physicians; and of those interested in physicians, their special education and their work. However, it is axiomatic that the prime responsibility of the physician is not his own welfare, but is rather the medical welfare of his patient; and that the prime responsibility of medical education is to train the physician for the best

possible care of his patients. Therefore, in developing our discussion, it is clear that if we proceed from the standpoint of the interest of the patient we are on sound ground; and that if through this we may develop the interests of the physician and of his special education, then, and only then, will they also be upon sound ground.

Specifically, it is submitted that:

(1) The patient has a right to expect, and should receive, that quality of medical service which is as good as current medical knowledge and facilities, as a whole, are potentially capable of rendering.

(2) Every high-grade physician is now a specialist; and this includes so-called general practitioners.

(3) The best medical care necessitates that the physician shall have whenever indicated, and without reserve, the aid of consultants, laboratories, hospitals and nursing.

(4) State medicine will come in America unless physicians wisely guide the trend otherwise.

(5) The problem of the cost of medical care must be solved for both patient and physician.

(6) Methods for certifying medical specialists are essential; are now, in part, with us; and will grow rapidly into maturity and potency.

(7) Medical education must become so organized, and is becoming so organized that it shall efficiently play its part in the premises.

It is obvious that, the first thesis is the key to the series; that this key is shaped by the last; and that the others are important collaterals. We may therefore turn in our discussion to medical education, viewing the other matters the while we proceed, or when indicated.

As we approach the end of the first third of the twentieth century we find the conditions of medical education and practice in America vastly altered from those which existed as the century began. Medical development has had its ample share of the rapid general develop-

* Address, by invitation, to the New York Post-Graduate Medical School and Hospital, Columbia University, Fiftieth Anniversary Dinner, Hotel Biltmore, January 30, 1932.

ment in matters scientific and material which the people of this century have constructed upon the foundations laid in the former century.

In medical education the most striking changes have been the disappearance of most of the numerous "independent" medical schools which formerly existed; the general trend of all medical education to be under the university aegis; the great improvements in medical educational facilities, including teaching hospitals; the elevation of the minimal medical educational standards permitted by law and by dominant public opinion; and the laying of the foundations of conscious and adequate university graduate medical education.

With a single exception all of the stated new century medical educational developments now have a stable and mature status; and are ready for refinements, whatever they may be. The exception is university graduate medical education, which is still youthful—though lusty, particularly in the very few universities where in it has been especially nourished.

That it behooves all American universities with medical establishments to give serious attention to the providing of adequate facilities for the special training of appropriately selected medical graduates in the science, practice and progress of medicine in its various clinical branches is now well recognized. The universities of Pennsylvania, Minnesota, Harvard, Tulane, and Columbia are already especially active; but the focussing of university thought and effort upon the matter is now quite general.

During the past decade there has been accomplished important pioneer work in this field. Precedents have been created where none existed; the goal has clearly been seen; ideas and efforts have become more lucid and definite—in contrast to the previous vague and casual ones; there have been constructed, conducted and continuously developed comprehensive plans of graduate medical education and equipment as a distinct university entity—in contrast to less efficient former efforts of a fragmentary, makeshift and ancillary character.

In proceeding we should have a clear understanding as to why there is the need for both undergraduate and graduate medical education—why educate youths for the work of physicians and then further educate some of these physicians?

An enlightened railroad president, for example, should no more think of trusting his major medical needs to a recent medical graduate than he would think of commissioning the construction of an important bridge to a recent engineering graduate. In both cases imma-

turity and inadequate special knowledge are faced; and in both cases the necessary maturity and knowledge can only ensue from further training and experience. As a matter of fact, in many states the new medical graduate cannot so much as make application for medical licensure. He must first obtain a specified minimal medical experience—usually in an approved hospital, even though his hospital contacts have been many during his medical undergraduate days. There are also many medical schools which do not grant the M.D. degree until the hospital internship has been completed.

However, hospital internships constitute but a beginning so far as real graduate medical education is concerned. The need for real graduate medical education arises from the conditions of the whole fabric of technical knowledge, skill and effort of the present as compared with the past. During perhaps the first century of our Nation, it was possible for one mind to grasp medicine as a whole and to practice it as it then existed—just as it was possible for the great Franklin, to perform every act of journalism as in his time it existed—news gathering, editing, typesetting, printing, publication. Today, Franklin would find a demand for a journalistic service which to be performed by a single individual would require that he be supernatural.

So it is with the physician. Medicine of today is far too vast for any single physician, and indeed anything save a considerable group of cooperative physicians, to practice if the patient is to receive the benefits which collective contemporary medicine is potentially capable of furnishing to him. Furthermore, clinical medicine is no more a completed thing than are the natural sciences. Medicine is based upon the natural sciences—it grows as they do, and with them—like them it becomes diversified—it becomes like them specialized through sheer, inescapable, mass-demand—it must have, as they have, specialized practitioners to exemplify its best service, and specialized investigators to widen its boundaries of knowledge and continue to increase its service.

How are physicians to become qualified as clinical specialists? By a process of self-education including experience gained by their trial-and-error essays upon unwitting patients? Forbid it! Through preparation in appropriate residencies or assistantships? To a significant degree, yes: this is the classic method.

However, all concerned should realize that the residency-assistantship is obsolescent as a sole and complete method in the premises. That method is an essential and indispensable portion of the normal method for the training of clinical specialists; but today and tomorrow

only the complete normal method should prevail; and it should be both normal and permanent in the same sense and probability of permanency as is the approved and prevailing normal undergraduate medical education of today and tomorrow.

There really exists a complete parallel—historically, developmentally, and currently—between the fundamental clinical training, involved in undergraduate medical education, and the special clinical training involved in graduate medical education. This truth, unfortunately, has only sporadic or vague appreciation; but its full appreciation and acceptance is vital to the success of the new medical educational effort in New York which looms in the minds of those foregathered here tonight. It is not possible on this occasion to do more than to state this truth; time forbids us to demonstrate the truth and its compelling implications.

The chief difficulty which presents itself to the logical and unhampered coordinate development of both undergraduate and graduate medical education is lack of a generally accepted, logical definition of the clinical goal of undergraduate medical education.

Given such a definition as to the clinical goal of undergraduate medical education and given its whole-hearted acceptance and practical use, undergraduate medical education would be improved; and there would be a similar improvement in what is known as the "general practice" of medicine for which undergraduate medical education is really the personnel feeder. Briefly, the field of graduate medical education would then be all forms of medical educational service indicated by the need of the times and unsupplied by undergraduate medical education.

There has been no lack of essays to define the goal of undergraduate medical education; there has been the weight of heavy authority behind various of these essays; and most of the essays have been made by those who are qualified. The troubles with most essays have been: conscious or unconscious bias; or failure to appreciate that any complete plan of medical education must include both undergraduate and graduate phases; or reluctance to disturb an existing condition; or aversion to disagreeable subtractions and additions; or disinclination frankly to define "general practice."

It would serve no purpose essential to this discussion to particularize under all of the foregoing heads. Let the statements themselves suffice, except in regard to "general practice."

General practice must be discussed and defined else there results an impasse. Everyone should agree that the practical goal of undergraduate medical education is to produce po-

tential general practitioners. This being agreed, how could one construct a logical undergraduate curriculum while lacking a frank definition of general practice?

The "general practitioner" or "family doctor" has been accorded admiration and love; and has been praised in prose, poetry and painting—all of which recognition he has well deserved. Much has been expected of him and much he has given. But today too much is expected of him. Unconsciously he is expected by his public to be a superman; and subconsciously he cannot help trying so to be.

The patient usually realizes clearly that medicine has made vast strides in recent years; and he fairly well realizes the increased advantage which that progress augurs for him; but he does not realize, or realizes but vaguely, that the whole of medicine is now far beyond the mastery of any one physician. It is common for him yet to expect the general practitioner to function "generally" as of yore.

The truth of the matter is that the general practitioner should be, can be, and, in his best expression, is really but one kind of a special practitioner—whether the fact be understood or otherwise. The sooner all concerned do realize this fact the better for all. Forbid any false inference that here is a knock against, or attempted dismissal of, the general practitioner. Quite to the contrary, the purpose is to aid and to magnify him; and, in so far as dismissal goes, it were but foolish to attempt the dismissal of the indispensable.

Imagine a medical army arrayed against and never ceasing to battle with physical human ills. Today this is a very modern army; and like other modern armies has many essential parts. The general practitioner occupies the most advanced post. He it is who delivers, by preventive medicine, the first assaults against diseases; and who receives, by curative medicine, the first shock of disease's attacks. He repels the enemy if he can; and often he succeeds; but the occasions arise when he must call for aid from other specialists who constitute the reserve arms of the medical service; and then it becomes their turn to exert their forces against the common enemy.

The expression "general practitioner" is therefore entirely misleading. Less misleading is the well-known "family doctor," though this is not entirely satisfying. Good expressions would be "family physician" or, simply, "physician."

However, let us use the accepted expression, general practice, and endeavor, briefly, to define it. The definition is one thing for districts having good hospital service; and another thing for districts inaccessible to such service. It is essential that medical practice of today

in its best sense shall have the command of truly efficient hospital facilities, be they of private or of community character. In districts lacking such hospital service, the general practitioner must often essay to be all that the term implies. He must do his best to serve every medical need of his district. In other words, he must essay an abnormal task simply because there is nothing else to do.

Fortunately, the railroads, highways, automobiles and airways of America, and the many hospitals within or accessible to rural localities have minimized the necessity for the abnormal type of general practice just cited, and it is obsolescent.

We may say at once that the normal type of general practice requires a knowledge of the principles of the basic medical sciences—biochemistry, anatomy, physiology, pathology and pharmacology, a foundation knowledge of the principles and usefulness of the recognized departments of preventive and clinical medicine, and an intimate knowledge of internal medicine, pediatrics and normal obstetrics. In brief, the general practitioner should really be a specialist in internal medicine with just as good a basic training in the various other departments of medicine as any kind of clinical specialist needs in medical departments other than his particular one.

This is the same as saying in a word that the practical goal of undergraduate medical education should be to produce graduates who are as nearly as possible qualified as beginners in the special practice of internal medicine. It means that the undergraduate curriculum should be carefully adjusted and balanced with this practical end in view.

The trouble with undergraduate medical education has been that such adjustment has not been fully maintained.

The tendency is now however to recognize that the undergraduate medical curriculum has been overburdened with material suitable only to the training of other clinical specialists, with a corresponding lack of sufficient emphasis upon internal medicine. The obvious remedy is to reverse the stated condition, to create adequate graduate medical education, and to exert therein the heavy efforts necessary for training in the other clinical specialties. Only in such a manner may the coordinate development of undergraduate and graduate medical education logically proceed.

Let us now turn to the remaining theses above set forth. The first one seems obvious, but it may be remarked that in order for the patient really to receive what he has the right to expect, due solutions must be found and applied with regard to the remaining theses. It will be sufficient for us to consider briefly

the matters of state medicine, cost of medical care and certification of specialists.

We are living in a time which social doctrine largely dominates. What is here meant is simply the benign types of social doctrine—of which the public school system is perhaps the most prominent of the numerous examples. In the medical field, probably the best examples are free or part-pay dispensaries, and free or part-pay ward beds. These medical services should no longer be regarded as merely "charitable." They have become so wide spread and of such great total magnitude that they constitute an imposing social whole, which, like the public school system seems ever to be waxing rather than waning, and which like the public school system should have definite public financial support.

The cost of the public school system is borne definitely and wholly by taxation, but the cost of contributed medical service is borne only indefinitely and inadequately by taxation—private donations, and unpaid professional services contributed by a host of physicians, provide the remainder. The large volume of deadheads and poor pays carried in the private practices of physicians also constitutes much of the free medical service of the land.

At this time there is much insistence, and considerable practice, in the matter of social policies such as old age pensions, unemployment insurance, mothers' and children's welfare grants, etc., and workmen's compensation laws have spread over the nation.

Physicians should all be alive, as many of them are, to the fact that it is an easy step from such precedents and trends to state medicine, which impends from various directions. One important direction is that state medicine is already effective to a greater or lesser degree in most of the world's great nations—America being the really notable exception. Another significant influence may be the eventuation of the current nationally organized American survey as to the cost of medical care. We all know that this survey reflects the widespread conviction that modern medical care costs more than our numerous and honored middle classes can afford to pay. Another way in which this conviction is often expressed is "only the rich and the properly hospitalized poor receive high grade medical care." Indeed who else potentially do receive the benefits of that combination of due hospitalization, nursing and medical specialists' services, and extensive medical supplies and equipment which are implied in the dictum?

We urge that state medicine would be an unfortunate extension of social practices—alike for patients and physicians. To the patient it would mean impersonal, perfunctory

medical services. To the physician it would bring a type of governmentally dictated servitude to replace his dignity of independent service. Therefore organized physicians should go forth mightily to meet and to destroy this threat ere it becomes an established fact.

Broadly speaking, the way to inhibit state medicine is to solve two problems: the cost of medical care; and the quality of medical care.

It is submitted that the solution of the problem of the cost of medical care is to be found in suitable insurance or/and financed installment payments, sufficient to supplement such portions of the cost as the public purse should assume. Trustworthy insurance corporations should sell appropriate medical care policies, which provident well persons will buy; and personal finance corporations should accept the installment promissory notes of those needy ones who have been ill, but who have been improvident previously—or notes of their relatives, if necessary. State medicine of some sort seems to impend as the alternative.

By insurance, we do not mean the usual disability, or "sick-benefit," policies; but rather policies to pay the cost of medical care, as needed and to those to whom the costs accrue, rather than to the policy holders themselves.

We have insurance and installment buying for nearly everything else—why not for the more important matter of medical care?

Now as to the quality of medical care. This point has largely been covered by what has previously been said herein. It boils down to providing the patient with all that current medical knowledge, skill and facilities render possible in his service.

Due medical care should begin with the family physician, who should complete that care insofar as he is fully qualified to do so. However, when the due medical care modernly demanded by the case extends to further specialization and hospitalization, then the family physician should intelligently manage the case by securing for it whatever additional services are needed; and by continuing a watchful guidance over the patient's interests during and after the rendering of such services.

Thus we are finally brought to the necessity of knowing which hospitals and which medical specialists are modernly worthy. Certainly they are not so merely because they hold themselves forth so to be. What is needed is that

their genuineness should publicly be certified by competent authority.

Such authority could be state licensure of successfully state-examined hospitals and of medical specialists—just as such licensure is now universally required for the internists who practise as family physicians. Perhaps such licensure will appear; but it is not necessary. Certification by appropriate groups of physicians is sufficient—and much to be preferred.

Certification of medical specialists by appropriate groups of their professional colleagues already exists to a limited extent. Reference is made to the certificates issued by the American Boards: of Ophthalmic Examinations; of Otolaryngology; and of Obstetrics-Gynecology. These examining and certifying groups having been formed and authorized by the organized and recognized practitioners in their special fields, their certificates merit the confidence of profession and public alike.

But why should clinical specialists' certification or licensure not be universal, rather than limited? This is a question to which the American Medical Association is now actively addressing itself; and we do not doubt that within a few years the added moral force of this great organization will have proved as potent in the premises as it has proved in various other medical reforms which it has undertaken.

Tonight we celebrate the Golden Anniversary of the New York Post-Graduate Medical School and Hospital, founded in 1882; and we also celebrate its new union with Columbia University College of Physicians and Surgeons, founded 115 years earlier, in 1767, the second medical school to be founded in America; and it is the prescience of the great and good results that shall flow from that union which looms before our minds. To honor and to good-speed this union is, in friendship, presented the esteem and good wishes of the oldest of American medical schools, founded in 1765, 167 years ago—that of the University of Pennsylvania, which in 1916 by merger with the Medico-Chirurgical College of Philadelphia, (founded in 1881) effected a similar union for a parallel purpose.

May these venerable, vital and progressive sister medical institutions ever continue, in the van, to advance side by side in their beneficent service to mankind.

CRIME DETECTION

The detection of crime consists in making a diagnosis starting from a few vague symptoms which escape the notice of an untrained investigator. A detective must be trained in a few fundamental principles which are analogous to the basic conditions which a doctor determines in every sick person whom he examines. A skilled detective makes an accurate observation of a scene of a crime, and is careful not to blur or obliterate

tracks and finger marks, or to disturb articles which may have been disarranged. He also takes measurements and photographs in order that others may reproduce the scene accurately.

A good detective records his observations in accurate, understandable terms, and writes a brief history of the case, and especially records the names of all observers or informants. To make complete records requires training and education.

The records are subject to all the errors and omissions of a clinical report, and are as necessary as the hospital records of a case. Yet, when made by an untrained and uneducated constable, they are likely to have the crudeness and obscurity which would be expected of an ignorant healer or cultist.

When a suspected person has been arrested, the police methods of examining him are often still more crude. The medieval idea of securing confessions under torture is still applied, and the front pages of the metropolitan newspapers are just now carrying vivid accounts of the death of a criminal from edema of his larynx which was fractured when the police officers choked him in order to obtain his confession. If a physician were examining a criminal under like circumstances, he would recognize the necessity of observing the suspect while he was in a mental state of suspense and apprehension at the same time that his physical body was as comfortable and relaxed as possible. A criminal, relieved of his immediate fears, will exhibit mental reactions which a trained criminologist will interpret correctly, just as a psychiatrist would judge a paranoiac by his mental reactions when he is not forced to answer.

Criminology is now in an early stage of its evolution into a science and practical art. Already a few specialists have entered the field, and have pointed the way to the establishment of centers, such as the Scientific Crime Detection Laboratory of Northwestern University, Chicago, at which those with an aptitude for detective work may be trained for positions as directors of police investigations in cities and counties. Such trained officers as these are needed on the staff of every district attorney.

A crime detection laboratory is a comparatively new idea in the practical application of the principles of crime detection. A method of the identification of the individual pistol from which a bullet has been fired is recorded in a leading article in this Journal of August 15, 1926, page 701. The effect of scopolamine on truth-telling by criminals is described in *Hygeia* for April, 1932. These are examples of current progress in the scientific detection of crime. These methods are being developed and standardized to such an extent that police officials in the near future will turn to laboratories for the solution of baffling crimes, just as epidemiologists rely on public health laboratories for the identification of the microscopic criminals that cause disease.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Doctors' Sons: While there are a great number of physicians who are sons of physicians, there are very few who belong to the third generation of active practitioners, as is shown by the short list of those whom the editors of this Journal have been able to list. This Journal of August, 1907, has the following editorial comment on doctors' sons:

"Doctors' sons pretty generally make good doctors; that is, if they decide to study medicine and be doctors at all, they succeed. When you hear a physician say that the practice of medicine is a dog's life, and that if he had it to do over again he would never study medicine, that patients are ungrateful and give him little thanks or pay, you may be pretty sure that his son will not study medicine; and if perchance he should,

he is terribly handicapped by a lot of bad medical traditions. The unsuccessful doctor does not let his son study medicine. The doctor's son who does study medicine is quite invariably the son of the man who was successful enough to find joy in his work, and who could wish his son nothing better than to enter into the calling which had meant so much to him. And the boy saw in his father's life something that excited his admiration to emulate and covet. As a matter of fact and observation the son of the really successful doctor commonly does study medicine; and I can name a number of such men who attained to even greater success than their fathers.

"However, the decision as to whether a man is successful or not does not rest with you or me, the decision is with him."

MEDICAL PROGRESS

Edema in the Newborn.—John Gibbens finds that while text-books describe congenital edema, edema neonatorum, scleroedema, scleroma, etc. no two authors agree as to the precise definitions. With the idea of simplifying the subject he has collected cases with edema as the leading sign. This has brought out the fact that the main etiological factors are cold and sepsis. It is essential that every practitioner and nurse should realize that cold is the commonest cause of edema in the newborn. The ordinary clinical thermometer with a low level of 96° gives a false idea of the actual temperature of the baby. A thermometer with a low level of 88° must be used, and the temperature must be taken rectally. Probably many infants are certified as having died from atelectasis, prematurity, or congenital debility when, in reality, death was due to the effects of cold. Edema may occur (1) if the infant is put in a warm bath immediately after birth, without having had a subnormal temperature, and (2) if the temperature is subnormal. In the latter case cold is a contributory factor, the main factors being feeble development of the circulatory system, cardiac weakness, and delicate and fragile blood vessels. Edema of the feet may depend upon the effects of gravity, and may disappear with change in posture. Usually all trace of edema has vanished by the age of three or four weeks. No treatment is required beyond keeping the baby's temperature normal. There is no sharp distinction between edema, scleroedema, and scleroma; in all probability it is merely a question of degree, depending upon the water-richness of the tissues and the distribution of the subcutaneous fat. The treatment of scleroedema is simple, namely, warmth at all costs—hot baths, hot bottles, massage of the limbs, and breast feeding. Since these cases resemble myxedema, thyroid extract ($1/8$ to $1/6$ of a grain, three or four times a day) has been given with excellent results. In an infant suffering from scleroma, a circumscribed, symmetrical fat sclerosis, the temperature is commonly raised and the infant has small plaques in the subcutaneous tissue, like multiple lipomata, over which the skin is reddened. With massage they usually disappear after a few weeks. Edema in the newborn may be caused by sepsis, in which case fever is usually present. Nephritis is found to be very rarely a cause of edema in the newborn.—*British Medical Journal*, May 7, 1932, i, 3722.

A Method of Preventive and Curative Treatment of Serum Reactions by Benzo-Salicylate Medication.—According to M. H. Vincent, reactions, mild or severe, following injections of horse serum are rather frequent, having been estimated at 40 per cent in adults and 12 per cent in infants and children. The very multiplicity of the medications that have been recommended for them is a proof that none of these has a constant specificity of action. It is very important before giving an injection to inquire of the patient not only whether he has previously received injections of horse serum but also whether he has ingested horse meat or horse blood or serum in any form whatever, [and may we add has worked in stables or taken care of horses] since such renders the patients sensitive and explains certain strong allergic reactions. As the result of researches made upon the cryptotoxins in general, and upon the antitoxic and cryptotoxic properties of the sodium salts of benzoic and salicylic acids in particular, Vincent discovered that the various substances of this nature have in addition very striking antishock properties. His method of applying his discoveries in a therapeutic way is as follows: As soon as the first symptoms of serum sickness appear, the patient is given a tablespoonful of a potion containing 6 gm. sodium salicylate and the same amount of sodium benzoate in 200 c.c. of excipient, at first once an hour, and afterwards once every two hours. These amounts may be increased, and in children they should be decreased. It is well to give each dose in weak tea or other warm drink. The symptoms of reaction, whether general or local, generally stop in a few hours. The fever falls; the edema and eruption diminish, sometimes a little more slowly, but the itching and pain cease promptly. In case of a patient who has been sensitized by an earlier injection of serum, the shock is more severe and the eruption more densely crowded. Nevertheless, the prompt employment of benzo-salicylated medication in the manner here described, and renewed whenever necessary, usually causes abatement of the symptoms from the first or second day. No less real is the service it renders in cases in which the allergic reaction is already completely let loose, for it has the effect of suspending the symptoms, although somewhat slowly. The use of the treatment for prophylactic purposes in patients who have at some earlier time had injections of horse serum, or even in other

patients, is a wise precaution, since one never knows when a reaction may occur.—*Bulletin de l'Académie de médecine*, April 19, 1932.

Prevention and Treatment of the Common Cold by "Glegg's Mixture."—For the prevention and treatment of the common cold E. P. Poulton recommends the application of massive doses of an inert substance to the mucosa of the nose and nasopharynx. Such a substance is "Glegg's mixture," so named by the writer because he first learned of it from Wilfred Glegg in 1921. The mixture consists of three parts of liquid paraffin and one part of white vaseline, flavored slightly with rose. By Glegg's mixture with menthol is meant a similar mixture containing $\frac{1}{2}$ grain of menthol per ounce, without the rose flavor. The application is made by means of a nasal pipette. It is best for the patient to lie down on his back in order to apply the mixture; a pipetteful should be driven down each nostril so that it is felt at the back of the nose. This method should be used as soon as the slightest rawness is felt at the back of the throat. In mild cases the application should be made morning and evening; at the beginning of a severe cold it should be applied four-hourly. Even in mild cases the treatment should be continued for two days, or the cold will return with its old severity. After the second twenty-four hours the applications can be quickly reduced. If a cold cannot be entirely aborted by this method, at least it develops into a relatively mild affair. It is better not to swallow the mixture if it can be avoided, as it may possibly produce looseness of the bowels. Poulton believes the beneficial effect of this treatment is due to the coating of the mucous membrane with the oily mixture, thus creating a less favorable environment for the infecting organism. If this point of view is correct, a massive dose must be used. This view also explains why oily sprays are ineffective; the volume of the material is not sufficient. The substance should be so thick that it only just runs.—*The Lancet*, April 30, 1932, ccxxii, 5670.

Complex Troubles of the Cardiac Mechanism in the Course of a Severe Case of Typhoid Fever.—E. Géraudel and Mouquin report that they observed important disturbances of the cardiac mechanism in a boy $10\frac{1}{2}$ years old during a severe attack of typhoid fever. The electrocardiac tracings were of special interest for their complexity and rarity. Anomalies of widely different types, generally classed under different headings, followed one another in succession, proving that typhoid infection may be the cause of serious disturbances of cardiac rhythm. All the phenomena were transitory,

and without doubt pointed to a lesion that was only slight or to a purely functional trouble. They evolved in a cyclic manner, becoming progressively aggravated and then ameliorated; during the course of the amelioration, they receded in the reverse order by the same phases as those observed during aggravation. Clinically the disturbances appeared inconspicuous, and could be regarded as nothing more than a sinus arrhythmia. Only through the electrocardiogram could their importance be recognized, as they were seen to pass from a nearly normal rhythm when the rhythm was rapid, to a mechanism closely approaching auriculoventricular dissociation when it was slow. This phenomenon was instructive, since it raised the question whether the arrhythmia known as "sinus," when regarded as a purely physiological phenomenon, or at any rate as benign, is not in reality a minor phase of more serious disturbances, linked, as in this case, by multiple connections with auriculoventricular dissociation and very grave troubles of cardiac rhythm. In a large number of tracings it was observed that at certain moments two ventriculograms were abnormally approximated to each other, their coupling interrupting the regular course of near-by ventricular beats, equidistant and wider spaced. Between the two close beats an auricular beat was interposed. This phenomenon must be interpreted as a "ventricular capture." In the classic hypothesis, this expression signifies that the auricle is at this moment leading on the ventricle, but to the authors it means that the auricle and the ventricle are controlled by the same mechanism; there is a parallel urging on of the auricle and of the ventricle by the sinus vestibule, and not an urge of the auricle by the vestibule and of the ventricle by the auricle. The precise explanation of the pathogenesis of these disturbances cannot be given in the present state of medical knowledge. The case shows, however, that in seeking the etiology of every anomaly of the cardiac mechanism, typhoid fever should be given the same consideration as such affections as acute articular rheumatism or diphtheria.—*Archives des maladies du coeur*, April, 1932.

Tooth Extraction and Chronic Infective Endocarditis.—Herbert H. Brown, writing in the *British Medical Journal*, April 30, 1932, i, 3721, directs attention to the very real danger of extracting teeth with apical streptococcal infection. Even if a large number of teeth are removed at one sitting it is not generally a very serious matter. But if for any reason the patient's resistance against streptococcal infection is low, there may be serious danger. The use of local anesthesia by infiltration of the gum increases the danger. There can be

no doubt that forcing a fluid under considerable tension into the comparatively rigid and resisting tissues must tend to carry any germs which may be present into these tissues, and so to the blood stream. Two cases of infective endocarditis following tooth extraction under local anesthesia have been recorded by L. Abrahamson (*British Medical Journal*, July, 1931) and Brown reports another case. In this instance the mode of onset of the symptoms and the course of the disease indicate a blood infection originating from the extraction of a tooth. Later following the extraction of three teeth under local infiltration the endocarditis was greatly aggravated and terminated fatally. In each of these cases there was preexisting valvular disease. It is, therefore, a wise precaution, especially in the case of an individual already suffering from valvular disease, or one who may be liable to have a weak resistance, to extract *one tooth* only in the first instance, under a general anesthetic such as nitrous oxide; to make a culture from the tooth, and to test the patient's blood for bactericidal power against it. If the blood has no bactericidal power, an attempt may be made to improve it by graduated doses of vaccine.

Prophylaxis and Treatment of Alveolodental Polyarthrititis by Artificial Mastication and by the Bacteriophage.—The observation of a case of alveolodental polyarthrititis following the sudden cessation of mastication on one side of the mouth, whereas up to this time both sides had been used energetically, led Pitsch to the belief that the point of departure for Riggs' disease lay in insufficient mastication, a belief that was confirmed by study of the maxillæ of skulls in the museum of natural history. Savages with teeth well used never have pyorrhea, while we know, on the contrary, the frequency of this affection in races fed upon rice which they swallow without chewing. Prophylaxis could easily be secured by reestablishment of the function of the jaws, which would restore these organs to a healthy state. When it is customary to swallow without having chewed, it is possible to practise artificial mastication away from the table upon an inert substance, and thus restore to the alveolodental ligament the tonicity that it has lost through lack of use. This method gives remarkable results, but many persons will not consent to submit to it until it is too late. The effect of artificial mastication will be much more marked if at the same time means are used to hold the teeth solidly in their place, such as a bridge or an immobile apparatus preventing all migratory movement where neighboring teeth have been lost, and combating the pressure of the tongue, which is one of the

main causes of alveolysis and formation of *culs-de-sac*. If the latter are once formed, all the microbes of the mouth will swarm there; pus will form, and the tooth will fall sooner or later. In such case it is evident that artificial mastication alone could not succeed, but must be supplemented by proper hygiene of the mouth. Pitsch has had extraordinary results from introduction of a bacteriophage. He has observed no disadvantages from its use nor any contraindications. Although the technique of application, as also the virulence of the bacteriophage, is yet to be perfected, there is every reason to believe that, with the aid of a rational oral hygiene in which soap and formalin products play a large part, and also aided by artificial mastication, the bacteriophage will succeed in preventing or curing this redoubtable disease which nothing up to this time has been able to reach. Pitsch is experimenting to find the bacteriophage which will produce the maximum effect in the minimum of time, for it is important to bear in mind that the subject cannot conserve the bacteriophage in his mouth for more than a limited period of time.—*Bulletin de l'Académie de médecine*, March 22, 1932.

Injection of the Umbilical Vein in Retained Placenta.—David W. Currie shows that in cases of retained placenta Credé's maneuver is not without danger, and statistics show that manual removal is attended by a high rate of morbidity and mortality. During the last five years at the Leeds Maternity Hospital, the placenta has been removed on 87 occasions; 28 of the cases became morbid and 14 proved fatal—a morbidity rate of 32.7 per cent. and a death rate of 16 per cent. This series included a large percentage of emergencies. In seeking to improve upon these figures, the author's attention was drawn to Jarco's procedure of injecting the umbilical vein. This consists in first making sure that the placenta is in the uterus by using the simple tests, supplemented if necessary by rectal examination. The requirements consist of a Record syringe, a large needle, and 200 to 300 c.c. of sterile saline. The cord is thoroughly cleansed for about eight inches from the vulva. This part of the cord is used because it is least likely to be soiled by feces and most likely to contain a patent umbilical vein. The saline is then slowly injected, and the physician awaits the onset of uterine contractions and delivery of the placenta, which usually occurs in from ten to forty minutes. As Jarco suggested that the separation of the placenta was caused by the tearing of the small veins it was thought that if the saline was injected faster there was more likelihood of this occurring, and so the Record syringe

was supplanted by Scannel's apparatus and a No. 20 needle was introduced. By this means 300 to 400 c.c. of saline was injected in two and a half minutes. On completion of the injection the placenta is expressed if it has not already been delivered. In nearly all the cases from the onset of the injection to the final delivery of the placenta not more than five minutes elapsed. This procedure affords an easy means of completing the third stage of labor, without the aid of any further instruments than the practitioner ordinarily carries in his bag, without the necessity of much preparation or anesthetic, with a fair percentage of success, and above all without the great fear of puerperal infection and risk of death which accompanies the manipulations now generally practised.—*The Lancet*, May 21, 1932, ccxxii, 5673.

Can a Single Fluoroscopic Examination Activate Latent Pulmonary Tuberculosis?—N. Tsamboulas states that he has had the experience on a number of occasions, after fluoroscopic examination of a person who was physically sound upon careful examination, and in whom the roentgen findings were negative,—such a person, for example, having come for examination with a view to marriage or for some similar reason—of observing the appearance of pulmonary symptoms a few days, or even a few hours, after the roentgen examination was made. Not infrequently it was a pulmonary hemorrhage that ushered in the symptoms. Further observation of such subjects led to the suspicion that the X-ray examination had had the effect of activating a latent tuberculous pulmonary focus. With a view to examining the validity of this conclusion, Tsamboulas made tests on 13 patients with manifest pulmonary tuberculosis, to determine the effect of fluoroscopy of 3 or 4 minutes' duration upon the rapidity of blood sedimentation, upon the total blood protein, and its individual fractions, and finally upon the basal metabolism. He observed that in all these patients the fluoroscopic examination caused a shift in respect to every one of these items. He then repeated the test upon 8 healthy individuals in whom pulmonary tuberculosis could with the greatest possible certainty be excluded. No change whatever in any of the items was observed in any of these persons. It could therefore be safely concluded that 3 or 4 minutes of fluoroscopy has no effect upon healthy individuals. Tsamboulas then tried the effect of fluoroscopy upon some remote region of the body, such as the pelvis or thigh, in persons suffering with pulmonary tuberculosis. He found that no blood changes resulted under these conditions. This proved that the changes in rapidity of sedimentation and in the protein

composition of the blood were not due to a direct effect of the X-rays upon the blood, which was altered by pulmonary tuberculosis in its physicochemical nature, but that they were the result of irritation of existing pulmonary foci. It does not follow, however, that occasional clinical exacerbations observed after fluoroscopy are also attributable to the focal reaction caused by the fluoroscopy. Tsamboulas is of the opinion that the seemingly healthy subjects who developed pulmonary symptoms immediately after fluoroscopy had latent foci whose stage of development at the time of the examination must have been labile to such a degree that the irritating effect of even a single roentgen examination was enough to produce a focal reaction and to cause an outbreak of the disease.—*Münchener medizinische Wochenschrift*, April 22, 1932.

Follow-up Examination of 27 Cases of Post-vaccination Encephalitis.—An account is given by Oskar Kudelka in the *Münchener medizinische Wochenschrift* of March 4, 1932, of the findings in 11 boys and 16 girls who had exhibited signs of infection with postvaccination encephalitis between 1928 and 1931. Tests were made with reference to motor power, superficial and deep sensibility, tendon and pupillary reflexes, organs of sense, and signs of ataxia. Somatic examination was followed by mental and psychic tests. Contrary to what has been reported by a few authors (Brückner, Duken), it was possible to bring about a complete cure of the disease. All that could be found in the way of rests of the affection was the presence in a few children of somewhat livelier reflexes, and in a single child, whose illness dated from May, 1931, a unilateral paralysis of the abducens, for which a good prognosis could be made, in view of the fact that in other cases the most severe manifestations of the disease (speech paralyses) had entirely disappeared after a time. In one child the disease had been followed by mental or psychic deterioration; some others, however, were considered to be the best scholars in the school. Throughout the examination, it was the older children among those undergoing primary vaccination who fell ill; the youngest child was 4 years old. The reaction to the vaccination, judging from the nature of the cicatrix, had been quite severe. All the vaccinations had been carried out percutaneously with a vaccination point. The one case of encephalitis following intracutaneous vaccination was not included in this study. Vaccination encephalitis is an affection which either results in death or is cured without leaving any sequels. In view of the histopathologic and negative bacterial findings, it seems questionable whether the results of the examination are in harmony with the concept of a true inflammation in the region of the central nervous substance.

LEGAL

JUDICIAL INTERPRETATION OF THE PRACTICE OF MEDICINE

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Very recently an interesting case relating to the practice of medicine was decided by the highest court of one of the mid-Western States that is of considerable interest.

The City of F— had enacted an ordinance which classified certain occupations and provided for their licensing. One of the classes coming under the enactment was that of "travelling specialists and physicians." It was provided that those belonging to said class were to be licensed by the City Clerk at a fee of \$50 per day. A punishment for failure to comply with these requirements was also provided.

A certain doctor from the City of K— in an adjoining State had been in the custom of making periodic visits to F—, where he was consulted by patients. He would advertise these visits in the newspapers of F— and by means of handbills. He styled himself a travelling physician and specialist. He had been licensed to practice medicine in the State in which F— was located. His residence was in K— in the adjoining State, and in that city he operated a chemical manufacturing plant known as the C— Medical Institute. Upon examining patients and deciding that they needed certain medicines, he would take money from them and the medicine would be sent them from his place of business in K—. He did not comply with the licensing ordinance above referred to.

One day when Dr. S— was in F—, so engaged in his profession, the city authorities advised him that if he did not cease his practice as a travelling physician and specialist in the City of F— he would be arrested and fined. He thereupon brought an action to enjoin the enforcement of the city ordinance. The doctor in his petition claimed that he was engaged in interstate commerce and that the ordinance was a violation of the clause of the Federal Constitution giving Congress the power to regulate interstate commerce. He further contended that the license fee was unreasonable and prohibited him from following his profession as a travelling specialist. On the trial the court refused to enjoin the enforcement of the ordinance.

The doctor subsequently appealed to the highest State court on the principal question as to whether or not he was engaged in interstate commerce. He relied on certain United States Supreme Court decisions which held: "All interstate commerce is not sales of goods. Importa-

tion into one state from another is the indispensable element, the test, of interstate commerce; and every negotiation, contract, trade and dealing between citizens of different states, which contemplates and causes such importation, whether it be of goods, persons, or information, is a transaction of interstate commerce." Dr. S— contended that his dealings with patients in the City of F— were merely incidental to the business of shipping the medicines to them from K—. He urged in support of this the fact that he exacted no fee upon examining a patient unless he decided that some of the medicine put out by his C— Medical Institute would be of help to the patient.

The court, however, ruled that the question involved was not one of interstate commerce, which is subject to Federal control, but rather a question of the practice of medicine which is not subject to any regulatory power of Congress. The court, having pointed out that medical practice may be licensed and that medical practitioners may be made to pay a tax, found that the facts justified a finding that Dr. S— in fact practiced medicine. The court's opinion was in part as follows:

"In the case at bar the examination of the patient, the observation of his symptoms and distress, the mental processes, reactions, and conclusions of the doctor resulting from such observation and the prescribing of appropriate remedies to correct pathological conditions discovered all had their situs in F—. These acts had no elements of interstate commerce. They were the acts of Dr. S., not the C. Medical Institute of K—. The state has seen fit to regulate the doing of these things by requiring one who does them to have a license to practice medicine. The right of the state to do this Dr. S. has recognized by obtaining and filing with the county clerk of W. county a license to practice medicine in the state. The City of F— has equally well recognized authority to license the carrying on of classified occupations within its limit. One of these is that of physician and specialist. That is what the ordinance in question purports to do. No doubt the ordinance provides a license for the practice of law within the corporate limits. No one would have the temerity to say that a lawyer could maintain an office in F— for the purpose of meeting clients on certain days in the week, and then,

because he maintained a library in K—, where he wrote his briefs, escape thereby the necessity to procure a license to practice law in the state where F— is located and to pay whatever license fee the ordinance of the city should require. When Dr. S. performed the acts which he alleged in his petition, he engaged in the practice of medicine. The source of the medicine he prescribed is immaterial. He might have made it a practice to advise his patients to go to some mineral springs for a cure, or to go to Switzerland for the wonderful sun baths for which that region is famous, or to Colorado for the benefit to be derived from the health-giving climate, and still be practicing medicine within the meaning of R. S. 65 (the section of the State statute)."

The court quoted from an earlier decision as follows:

"In the main, the cases regard diagnosis as the test to determine whether a practice or treatment is included in the terms 'medicine' and 'surgery.' This is a practical test. A doctor who advises his patient to sleep in the open air is treating him. Such advice, however, is based upon a knowledge of the patient's condition obtained by diagnosis. The defendant professed to be able to ascertain by examination of the patient the cause of his trouble—a result rather beyond that which ordinarily attends the diagnosis of the regular practitioner. The method or extent of the examination is not the controlling feature. When the practitioner makes such examination of the patient as he regards as sufficient to indicate to him the cause of the trouble, and to indicate its proper treatment, he has diagnosed the case."

The court said in conclusion:

"Finally, it may be said that the acts performed by Dr. S. in F— constituted practicing medicine regardless of where his prescriptions were filled. The municipality has the authority to require one practicing medicine within its limits to pay a license fee. The regulation of the practice of medicine is a field of legislative control over which the federal government has no jurisdiction."

It should be noted that the court in deciding the case did not consider whether a tax of such an amount as fifty dollars a day was unreasonable.

In the State of New York evasions of the law regulating and licensing the practice of medicine have arisen. The opinion in the case referred to seems to be in complete accord with the rule in this State. In a recent case of prosecution for the crime of practicing medicine without lawful authority and registry, the defense was that the defendant did not administer drugs and therefore did not practice medicine. The Appellate Division sustained the conviction, stating the law in its opinion in part as follows:

"To confine the definition of the words 'practice medicine' to the mere administration of drugs or the use of surgical instruments would be to eliminate the very cornerstone of successful medical practice, namely, the diagnosis. It would rule out of the profession those great physicians whose work is confined to consultation, the diagnosticians, who leave to others the details of practice."

And further:

"Diagnosis would, therefore, seem to be an integral part of both the study and practice of medicine, so recognized by the law as well as common sense. The correct determination of what the trouble is must be the first step for the cure thereof. It is a well-known fact that the disease popularly known as consumption may, if discovered in time, be arrested, if not entirely eradicated from the system, by open air treatment in the proper climate, and that in such cases use of drugs has been practically given up. Would the physician, in such a case, who, by his skill, discovered the incipient disease, advised the open air treatment and refrained from administering drugs not be practicing medicine? It may be difficult, by a precise definition, to draw the line between where nursing ends and the practice of medicine begins, and the court should not attempt, in construing this statute, to lay down in any case a hard and fast rule upon the subject."

CLAIM OF NEGLIGENCE IN ADMINISTERING ANTITOXIN

While a surgeon was on duty at a large city hospital, he was called to the accident room to treat an emergency case. He examined the man and found that he had a punctured wound of the palmar side of the palm of his left hand which he had sustained while at work. He had been brought in for treatment as a workmen's compensation case.

The doctor determined that because of the na-

ture of the wound it would be advisable to administer tetanus antitoxin. The patient consented to the injection, and the doctor undertook to administer a prophylactic dose of 1,500 units. He injected the antitoxin by a hypodermic in the patient's arm, but as the doctor removed the needle he found that it had broken off at the hub and that the entire needle remained in the tissues. At once the doctor told the patient what

had occurred and impressed upon him the necessity of immediate removal of the needle. The doctor took x-rays of the hand and within fifteen minutes after the needle had broken, attempted to remove the same under an anesthetic of novocaine. After probing for several minutes unsuccessfully, the patient requested the doctor not to continue the search and agreed to return a few days later to have the needle removed.

At the appointed time, a second set of x-rays were taken to determine whether the needle had shifted its position since the earlier attempted removal. Again, under local anesthetic, the doctor made a further attempt to remove the needle. After about five minutes of this procedure, the patient requested the doctor to let the matter go altogether, telling the doctor that he thought it

was best to leave the needle alone as it probably would not cause him any trouble.

The doctor never saw the man thereafter or heard anything more of the matter until a summons was served upon him in an action claiming alleged malpractice. It was charged, in substance, that the fact that the needle broke and that the doctor failed to succeed in removing the same after two attempts, was clearly malpractice on his part.

The suit was apparently brought in the hope of obtaining a settlement from the defendant, for when the case was reached for trial on the calendar, no one appeared on behalf of the plaintiff, and on motion of the attorney for the defendant the complaint was dismissed and judgment entered in favor of the doctor.

TREATMENT OF A FRACTURED LEG

A middle-aged man was brought to the office of a doctor engaged in practice in a rural community, for treatment of injuries which he had sustained when he had been struck by the limb of a tree falling on his right leg. The doctor made a superficial examination and noted that the man's condition was that of a serious fracture of the said leg, for the fibula was protruding from the leg. He immediately arranged for the patient to enter the nearest hospital, where he was brought under the care of the chief surgeon associated with the staff of said hospital.

An x-ray examination was promptly made which showed a compound fracture of the right fibula and a comminuted fracture of the right tibia with marked anterior overriding. The man was put under an anesthetic and an attempt was made to reduce the fracture by the closed method of reduction. This was found impractical, for the fragments persisted in sliding past each other, and there was no means of keeping them in satisfactory position.

Two days later another attempted reduction was made, this time by the method of open operation and a Lane plate was applied to the tibia, using two screws above and two below the point of fracture. The fibula was found to fall in satisfactory apposition without the use of a plate or wire. The leg was put up in plaster of Paris, and a small drain inserted through the incision.

Infection developed as a result of the compound fracture and it was necessary to cut a large window in the cast in order to apply wet dressings thereto. Drainage was provided for the infection for a period of three weeks, at the

end of which time the surgeon in charge of the case decided that the safest method would be to remove the Lane plate. After this was done, the leg was put up in extension on a Balkan frame with splints, traction being applied by adhesive straps to the foot and lower leg. After this had remained on for a relatively short period of time, the patient refused to permit the extension to be continued and ordered his leg freed from the splints. He was throughout the entire period of treatment a very unsatisfactory patient, being extremely non-cooperative. The extension and splints were removed and while at this time the bones were found in good apposition, it was carefully explained to the patient that if his leg was not kept in splints and in extension, he would in all probability have a deformed leg as a result.

After the patient had remained in the hospital about three months, and when his leg had not improved sufficiently to justify his leaving the hospital, he insisted upon leaving and returning to his home contrary to the emphatic advice of the doctors.

The patient nearly two years later brought suit against both the doctor whom he had first consulted and the surgeon who had charge of his case at the hospital, claiming that due to their malpractice his fractured leg had never been reduced, and charging them with responsibility for the infection that had developed, and claiming that due to their negligence he had been made a cripple for life. The case was tried before a judge and jury in the Supreme Court, and after the testimony had been submitted to the jury a verdict was returned in favor of the defendants exonerating them from all charges of malpractice.

THE DAILY PRESS

THE MODERN DRUG STORE

The "Doctor Shop" of a century ago, run by the village doctor, as his own technical establishment, evolved first into a store for the sale of drugs; and then into a cosmetic shop; and finally into a general store. An investigation into what a modern drug store actually sells is described in an article in the *New York Times* of July 5, as follows:

"In the course of a national survey of drug stores, government statisticians checked the movement of 17,000 customers visiting a certain store in a metropolitan district. The *Journal of Commerce* reports the results. It was found that for 7,800 of these patrons, or more than 45 per cent, the soda fountain was the first point of call. The tobacco counter attracted 2,899. Nearly 3,000 visited the candy counter and 1,040 went to the section where toilet goods are sold. Only 1,743 or

about 10 per cent, called at the counter selling medicines and doctors' prescriptions.

"These figures tend to confirm off-hand impression that the druggist is rapidly evolving from an apothecary into the proprietor of a department store. Almost anything small enough to be wrapped and carried can be purchased of him. His choice of wares ranges from fountain pens to waffle-irons and from safety razors to free verse. At his hospitable counter he serves not only soda but all the ingredients for breakfast, lunch and dinner.

"Doubtless his functions have changed greatly since the days when his symbol was the mortar and pestle, rather than the Neon lamp playing upon a display of golf balls and bathing-caps. He is less the scientist that he used to be, but a more convenient neighbor."

CUTTING A WIDE SWATH

The expression "He cuts a wide swath," is now an insinuation that some one is making a big show in a sporty way. The expression was originally one of high honor and was applied to the mower whose lane of cut grass or grain was unusually wide as he advanced down the field swinging his scythe or cradle. To win the mowing championship of a town a hundred years ago was the highest evidence of manly strength and endurance; and many a man has ruined his heart and his health in trying to maintain a family record set by a giant brother. Commenting on the record of a Pennsylvania champion, the *New York Herald Tribune* of July 17 says:

"All harvesting methods have changed so utterly that even in the country people exist who never saw illustrated the literal meaning of the phrase 'to cut a wide swath,' nor realize the prestige that once went with such a manly accomplishment. They would only look blank, should one speak to them admiringly of 'Michael Cromer's record.' Yet on the 12th day

of July, 1858, in a field near Mercersburg, Michael attained to what ought to be deathless fame, performing a feat of power and prowess probably never equaled. The tale is still told in Pennsylvania of how between sunrise and sundown he cut twelve and a half acres of wheat by the swing of his cradle.

"This cradle was made especially for him, and was a pattern of strength and comeliness. The blade was five inches wide by sixty-five long and made of 'silver steel.' Once every two hours, as he swung it, Michael took a little broth and also whetted the scythe, but halted for no nooning. The yield of that day's work was 365 sheaves. The master cradler was thirty years old, 6 feet 3 inches tall, and weighed 230 pounds. He made an average of twenty-two clips a minute over a swath eleven feet wide and five feet deep, which did not vary even when a thunderstorm came up and his great blade flashed with lightning in the gloom. And that, children, is cutting a wide swath. It takes a man to swing a cradle."

CHAIN LETTERS

Every doctor who is a victim of a chain letter may find possible comfort in the following editorial in the *New York Sun* of July 7:

"That mythical American captain in Flanders

who is supposed to be the originator of the most annoying of contemporary chain letters had his prototype a century ago. On June 23, 1832, the *London Spectator* relayed a Dublin paper's report

that many of the Irish were to be seen running and riding over the midland counties with a piece of burning turf, part of which was left at every house along the way, with the exhortation:

"The plague has broken out; take this, and while it burns offer up seven Paters, three Aves and a Credo, in the name of God and the holy St. John, that the plague may be stopped."

"Whoever received a piece of the burning turf, according to the century-old report, rested under an obligation to take turf of his own, set fire to it and run to at least seven other houses where no burning turf had been left. The

penalty for failing to meet this obligation was the cholera itself. Among the superstitious of that day as among the superstitious before 1832 and since then is that earnestness accompanied by a threat compels belief. The priesthood then disowned responsibility for the charm, just as, a century later, it was to disown responsibility for the chain. The communal carrying of lighted turf seems laughable now, but is it any more ludicrous than the current fad for writing chain letters? Obviously the practice gives a background of antiquity to the chain letter: Professor Frazer probably could trace it back to the cave man."

LIGHTNING AND SOUR MILK

The *New York Sun* of July 14 has the following interesting comment on the persistence of the popular belief that a thunderstorm will turn milk sour:

"If the iconoclasts of the Federal Department of Agriculture think they can shake public confidence in the venerable belief that thunder sours milk, they are as credulous as they suppose other folk to be. Merely saying it isn't so, or presenting evidence to prove it, will not do the business. To have her milk soured by a summer thunderstorm is an inalienable right of every farmer's wife, regardless of what the bright young men in the Department of Agriculture have to say.

"What every farmer's wife knows is that often when just before a shower she tasted the milk set out in crocks for the cream to rise, it was sweet, but that when she tasted it again soon after thunder it was blinky. If thunder didn't do the damage, what did? To this the Department of Agriculture has what purports to be

an answer. It says that just before a thunderstorm the weather is likely to be hot and humid; that this moist heat is especially stimulating to bacteria; that it was the heat and the humidity before the storm, not thunder, that helped bacteria to turn the milk sour. It goes so far as to say that if milk is kept in an icebox nothing short of an earthquake will turn it sour.

"To this the only appropriate rejoinder is: 'Is that so?' Whatever the explanation, whether heat and humidity or thunder ought to be blamed, there are stalwart American citizens who will insist upon holding to the ancient theory. Our grandmothers believed it before bacteria were heard of. Besides, a proper place to keep a lot of milk for the cream to rise is in a good, old-fashioned spring house or on airy shelves in an old-fashioned cellar. If the thunder does turn a little of it sour now and then, there is usually more to be had from the sources of the original supply."

INVESTIGATING ILL TEMPER

The *New York Times* of May 6 has the following editorial comment on a serious investigation of outbursts of temper:

"The *London Times* prints an account of a Missouri professor who devised a method for testing the angry passions of his students. His scheme has not only benefited mental research, it has improved the tempers of the young men and women.

"Students carried a diary with attached pencil wherever they went. Every time they found a fit of rage coming on, they made a note of the fact and the cause. By the time they had set down their emotion it had mostly evaporated, as

if he had counted ten before striking or saying a naughty word.

"Some of the professor's newly discovered facts are that women get angry six times to four for men, and that of every hundred tantrums all but fifteen were caused by disregard or insufficient respect for the subject of rage. If anger is bad for the health, it is strange that women, with their record of fury, should live longer than men. The English comment is that this proves their innate toughness. But it is just as likely that most of their little explosions would not be considered by men worthy of inclusion in 'the mad book.'"

OUR NEIGHBORS

CRIPPLED CHILDREN IN NEBRASKA

The July number of the Nebraska Medical Journal contains an article read on May 12th before the Nebraska State Medical Association on Crippled Children's Clinics. The work originated at the State meeting of the Elks in 1929, and the development of the work is described as follows:

"Contact was established with the division of Rehabilitation of the State Department of Vocational Education and together they formulated objectives and plans.

"Wisely the committee chose to supplement rather than duplicate existing agencies—There was seen to be a gap between patients and facilities for treatment. This gap they sought to bridge.

"It was fully understood that clinics are primarily the function of physicians, therefore no infringement upon their particular sphere could be permitted. The relation of lay groups to the clinic must be essentially the same as that of church organizations to their endowed hospitals. In short the Elks assume responsibility for ways and means; the physicians do the work of examining. Physicians are not asked to give free treatment; this item of cost is to be met through county or state funds and voluntary contributions.

"The State was divided into nineteen districts known as Elk Jurisdictions and the work confined to one district at a time. The Beatrice Jurisdiction comprising all of Gage and part of Jefferson, Saline, Johnson and Pawnee counties was chosen for the initial attempt. This area contains approximately 40,000 people and is the smallest of the jurisdictions.

"During this canvass the field man was careful to get the individual reaction of physicians to the project so that when the material evidence was submitted to the county society, there was no dissenting voice to the proposal of holding a clinic.

"The final step in organization was the creation of a permanent general committee to be entrusted with the follow-up work. The personnel consisted of representatives of the medical society and participating civic bodies. The duties of this group are to pass on the

of patients appealing for aid, direct proper channels, approve expenditures and maintain contact with the may find personally or by letter. Much of the trial in the had by the patient depends on "That mythic.

the tact and perseverance of this committee. Parents often need to be stirred to action in the interest of these unfortunate children."

The results of the free clinic are described as follows:

"Eleven months have passed since the first clinic, time sufficient to give some idea of actual results. Thirty-three patients were examined though only thirty records are available for analysis. Grouped as to cause of disability they were:

- Poliomyelitis—10.
- Congenital Deficiency—6.
- Bone Tuberculosis—2.
- Birth Palsy—2.
- Club Foot—2.
- Arthritis—2.
- Spina Bifida—2.
- Traumatic Injury—2.
- Flat Foot—1.
- Epilepsy—1.

"Eighteen were favorable subjects for treatment; twelve should be classed as permanent institutional cases. Of the eighteen favorable cases ten could be treated at local hospitals or at home. Ten out of the entire group needed partial or entire financial aid.

"To date, fifteen clinic patients or fifty per cent are accounted for. Ten carried through the advice received—nine of these were benefited; one a three months old infant with spina bifida and congenital dislocation of the hips died following operation. Four others were found to be under satisfactory treatment and have continued as they were. One died of intercurrent disease.

"So far as the follow-up records show fifteen have not availed themselves of the advantages offered by the clinic."

Dr. C. P. Fall, a member of the Central Committee commented on the psychological attitude of the parents as follows:

"It is estimated that the average clinic represents a contribution of professional time and skill amounting to \$1,500.00.

"Parents are loath to let other people know their children are in any way defective. They are very neglectful, and very ignorant. When you start action, the psychologic condition is this: They resolve this question in their minds: 'If I take my child to the doctor, I

RELIEF FROM NEURITIC PAIN-

The same therapeutic agent which has proved so valuable in the alleviation of pain, reduction of swelling and increase of motion in arthritic and rheumatoid conditions is also proving unusually effective in relieving the pain associated with the various forms of neuritis.

A record of 582 cases classified as neuritis, showed definite improvement in 84% following treatment with Farastan.

Let us send you the latest digest of the published work and full size package for clinical trial.

is inadequate and will not insure competent service, or where the contract denies the patient the right of free choice of physician, or where competitive bidding for the contract is involved, does in fact constitute a violation of medical ethics of the A.M.A., Chapter 2 (Section 2, Art. VI). Under this ruling, each case will be decided upon its merits, and where these factors exist, singly or in combination, a county society in Texas will be well within its rights in requiring that contracts be abandoned which are thus held to be offensive."

The report of the Councilors to the House of Delegates assumes that certain forms of contract practice are proper, such as salaried doctors in the employ of Departments of Health. It also enumerates five principles under which contract practice is unethical, as follows:

"1. When the compensation received is inadequate, based on the usual fees paid for the same kind of service by the doctors in the same community.

2. When the compensation is so low as to make it impossible for competent service to be rendered.

3. When there is competitive bidding in order to secure the contract.

4. When a free choice of physicians is denied.

5. Solicitation of patients, directly or indirectly."

ANNUAL REGISTRATION IN PENNSYLVANIA

The annual registration of physicians, after the plan adopted by New York State, is attaining a growing popularity among the States, as the arguments in its favor become increasingly apparent.

What the medical leaders of Pennsylvania think of the Annual Registration Law of their State is shown by the following editorial in the June number of the *Pennsylvania Medical Journal*:

"A register of licensed practitioners is a public obligation of every State board. In Great Britain and some other countries the placing of a physician's name on the official register confers all the privileges of licensure.

"With the best of State board records, after the passing of a number of years, the licentiate is frequently lost sight of, making it difficult to determine if he is still active in ethical practice, deceased, or removed from the State.

"The advantages of annual registration are clearly set forth in the comprehensive article of Dr. Engberg of the Minnesota Board published in the March Bulletin. Periodic registration has been referred to as the salvation of reputable medicine in this country, and it certainly exercises a distinct leverage on the unlicensed practi-

tioner. It constitutes a reliable directory that will be a valuable source of reference for the public as well as for the medical profession.

"The process of annual registration as now conducted does not cause any particular annoyance to the practicing physician, and the fee is moderate. The fees are also a fund that can be devoted to law enforcement, thus distributing the burden of expense to a certain extent on those who are most concerned with its maintenance of licensure requirements and proper enforcement procedures. Annual registration is distinctly an advance in the right direction.

"Pennsylvania has an annual registration required by the medical practice act, effective in 1926. A fee of \$1 or such amount as the Department of Public Instruction may see fit is charged, and payable January 1 of each year. There is a penalty of a fine of \$10 to \$100 for failure to register. The secretary reports they have an appropriation of \$65,000 every two years which is not secured by special taxation of the State.

"The secretary believes annual registration advantageous as it 'gives a complete list of licensed physicians which is used to check violations, and is a valuable aid in securing law enforcement.'"

BIRTH CONTROL IN MICHIGAN

The attitude of the Michigan State Medical Society toward birth control is set forth in the following semi-official letter by Dr. B. R. Corbus, chairman of the Council, printed in the July Journal of the Society which records the proceedings of the Council:

"The Council of the Michigan State Medical Society looks upon this matter as a controversial subject, and has not been willing, when the matter has previously been brought up, to take such action as would commit the Society to a definite policy. The Executive Committee, speaking for the Council by Authority, and for the profession as a whole, believes that, while technically the matter is a medical subject, it remains mainly in the domain of Sociology. We believe that there is something to be said on each side of the controversy. We know that there are members of our profession who look upon this movement as a definite social-economic problem, others who feel that it is a definitely personal matter, and still others who oppose the movement on religious and moral grounds. Until there is a greater unanimity of opinion in the profession and in Society in general, we believe that the Michigan State Medical Society, as a unit

of Organized Medicine, should not take the formal position of an advocate.

"If and when Society agrees on the legitimacy and propriety of contraceptive measures, we believe it is for the physician to guide, control and safeguard the methods employed. The necessity for this we realize has been, to a considerable extent, recognized by the leaders of the Birth Control Movement.

"We see no reason why individual members of the profession, who are convinced of the wisdom of their course should not take an active part in the movement as individuals, but we do not believe that we are, at this time, ready to put the stamp of approval upon it.

"We feel that it is not unlikely that the time is approaching when it will be incumbent upon Organized Medicine to take a stand on this question. What that stand will be depends somewhat upon the form of the activities of the Birth Control League.

"If we look upon this movement as an experiment in Sociology, then the doctor is, by virtue of his professional contacts, in an unusual position to determine for himself whether the good that is to come out of this movement is to well over-balance the possible evils. Once convinced that the good predominates, he will have a great desire to have Organized Medicine further the project."

GRADUATE EDUCATION IN OKLAHOMA

The minutes of the House of Delegates of the Oklahoma State Medical Association printed in the June Journal of the Association, contain the following report on graduate education and motion picture films:

"I have been asked to report on the work that has been done in the Medical Extension Post-Graduate Course and the motion picture films. The University Extension Department very kindly prepared a map to show this (demonstrating map). This will show the work that was done. You have probably noticed the report of the Secretary relative to finances that \$700 was spent this year for post-graduate work and \$350 that was contracted for last year. The courses in gynecology and obstetrics are marked on this map by green dots. These were held at five centers with a total attendance of 331. The course in surgical diagnosis was also held in five centers with an attendance of 418. The cost to the State Medical Society was \$350 for each of the two courses, the County Medical Societies where the courses were held meeting any other expense. A total of 749 attended, making the cost to the State Medical Society less than a dollar a head. An-

(Continued on page 941—adv. xvii)

(Continued from page 940—adv. xvi)

other course was put out by the Extension Department, the State contributing nothing to the expense, the members of the County Societies contributing \$10 apiece—that was put on in the northeastern part of the State. Ninety-one took another course at Oklahoma City and forty-one attended a course in Ear, Nose and Throat. As Chairman of the Committee that has been interested in this post-graduate work I feel that our money has been well spent in reaching 749 at a cost to the Society of \$700. Seven hundred dollars has been put in the budget of the State Society to carry on this work for another year.

"And now just a word relative to the motion picture films. This map will show the centers in which these motion pictures have been shown. I can see no reason why they have not been more widely circulated. We have now fifteen films. There are four reels on forceps delivery, three on eclampsia, two on acute appendicitis, one on benign prostate hypertrophy and three on infections of the hand. These have been seen by 850 physicians throughout the State as near as we can figure, giving each County Society its membership. Probably more doctors than that have been present,—many times there is someone from the outside. More publicity should be given to the films. Probably more County Medical Societies would use them if they knew just how to get them. The only cost is the expense to and from Norman, and the only requirement that they be shown by a licensed operator. If the County seat does not have a picture show with a licensed operator, one can be sent out from Norman, the cost simply being his expense on the road. That is all it will cost. Or for \$15 or \$20 they will exhibit these films, bringing their own machine and putting them on. I am going to suggest that more publicity be given them in the Journal and see if more of the County Societies will not become interested in this method of instruction."

CULT PROPAGANDA IN NEBRASKA

The *Nebraska State Medical Journal* for July has the following editorial comment on an indirect appeal for support of an initiative petition to change the Constitution so as to favor the cultists:

"The state has been flooded during the past sixty days with propaganda for 'medical liberty' presumably by a non-medical cult whose sole aim is to nullify the provisions of the Basic Science law enacted some four years ago.

"The literature broadcast would have the reader believe it is propaganda against com-

pulsory vaccination, diphtheria antitoxin, etc., which it is not. It is a veiled attempt to befuddle the public into signing an Initiative Petition calling for an amendment to the Constitution as follows:

"Proposed Amendment to the Nebraska Constitution:

"No law shall be enacted or effective respecting the establishment or perpetuation of any exclusive method or methods of healing in any circumstance, nor infringing upon the free exercise of the right of any person to receive any method of healing, treatment or prophylaxis he or his guardian may choose.

"No law shall be enacted or effective whereby an applicant for a license to practice a certain method of healing shall be examined as to his qualifications for that method by any other person or persons than practitioners of such certain method of healing."

"Flimsy and silly as this appears to thinking people, there is a real danger that the necessary 45,000 signers may have been obtained by July 1st to get the proposition on the ballots for the November election. In that case the

medical profession must arise to its duty and see to it that it meets with a handsome defeat at the polls.

"It was thought when the Basic Science law was passed, and all those engaged in healing the sick placed on an equal basis of knowledge of the sciences fundamental to medicine,—that the matter was settled forever; but too many persons without a scientific foundation of any kind want to practice the healing art. Hence, this propaganda."

THE TEXAS JOURNAL

The following editorial in the April issue of the *Texas State Journal of Medicine* describes Volume XXVII of the Journal, which is completed by this issue:

"Last year there was a total of 1,688 pages, of which 750 were advertising (counting three pages for each unnumbered advertising insert, of which there were twelve), and 938 were reading pages. This year the total is 1,576, of which 644 are advertising pages (again counting three pages for each unnumbered insert, of which there are sixteen), and 932 reading pages. There has been,

(Continued from page 942—adv. xviii)

therefore, a decrease of 112 pages, of which 106 are advertising pages and 6 reading pages.

"Thus, it will be seen that despite our decrease in advertising patronage, this volume almost exactly approximates its predecessor in regard to reading matter. Unless there is an increase in advertising it will be difficult to maintain the standard. We appeal to our readers to use whatever influence they may have with advertisers of ethical goods to patronize the Journal.

"In the following comparison between the division of reading pages of last year's volume and the present one, it will be observed that the original article sections differ by only one page, and that the greatest difference is in the miscellaneous items section, which shows an increase of 8 pages in the present volume over that of last year. This increase was due entirely to the more extended program of the annual session, which this year contains synopses of papers to be presented before three different sections and the General Meetings. We believe that this extension is worth-while and will be appreciated by all concerned.

"Our reading pages last year were divided as follows: Editorial, 97; Original Articles, 466; Miscellaneous Items, 86; News, 17; Society News, 101; Auxiliary Notes, 49; Death Notices, 30; Book Notes, 23; Transactions, 70. The index is among the miscellaneous items.

"This year the division is as follows: Editorials, 78; Original Articles, 466; Miscellaneous Items, 97; News, 21; Society News, 100; Auxiliary Notes, 44; Deaths, 29; Book Notes, 23; Transactions, 75.

"It will be noted that the principal cut in our reading pages was in the editorial department, where we thought the cut could best be made. It is the policy of the Journal to stress the production of scientific literature by our members. Our editorial efforts are devoted primarily and principally to the necessary propaganda among ourselves. Our Miscellaneous items, including all of the rest of the Journal are purely a matter of passing interest and public record of medical events of our day.

"As heretofore, there will be an exhibit at our annual session, comprising bound volumes of past numbers of the Journal and preceding volumes of Transactions, together with numerous medical journals, including the several Association-owned journals published in this country. Our package library service will be demonstrated at the same time and in the same exhibit."

WOMAN'S AUXILIARY IN TEXAS

The June issue of the *Texas State Journal of Medicine* contains the following opinion of the Woman's Auxiliary expressed by Dr. J. O. McReynolds, in his Presidential message to the House of Delegates on May fourth:

(Continued on page 944—adv. rx)

Thank You Doctor

The baby is doing splendidly and Tom and I are so pleased.

When you first told me that Junior would have to have bottle feedings I thought I was due for a lot of trouble and work because I remembered what a time my sister had when her baby was on the bottle. She sent for a formula that was advertised to be recommended by many authorities, but something was wrong. She used to spend hours in her kitchen mixing this, that and the other thing. And in spite of all her trouble, her baby fretted and cried and didn't gain properly.

This S.M.A. you have prescribed for my baby is a new one to me. In fact, I have never seen it advertised. But, believe me, it works like a charm and it is so simple to prepare—no fuss or bother at all.

Junior reaches to take the bottle right out of my hands and drinks it all up. And he's the best child. Always happy when he's awake, and sleeps the whole night through.

And talk about a picture of health! I believe he would take first prize in any baby contest.

I'm going to bring him down to your office Wednesday as you suggested. That S.M.A. folder you gave me says even a breast fed baby should be under the supervision of a physician and I think myself that it's better to keep the baby well than to wait until trouble starts.

We certainly want to thank you for bringing our baby along so well, Doctor. It increases our confidence in you as our family physician. Tom has already "said it with dollars", but I wanted to thank you personally, too.

And I'm going to persuade Mrs. Brown,—that's my neighbor with the baby that's not gaining—to come along on Wednesday so you can prescribe the proper diet for him too.

Trial supply of S.M.A. Because S.M.A. has won favor un-offered without charge under typical conditions we are quite willing that you should try it in your own practice and under your own control. To make this easy we offer you a generous trial supply without charge or obligation. Simply attach the coupon to your prescription blank or letterhead.

S.M.A. Corporation. 4614 Prospect Avenue, Cleveland, Ohio

THE ABDOMINAL SUPPORTER CO.

47 West 47th Street

New York City

Aurora Health Institute

Mendham Road, MORRISTOWN, NEW JERSEY

Beautiful country; elevation 700 feet; only one hour from New York. Open all year. Diet, electro-therapy and hydro-therapy. Personal medical supervision. Suitable for convalescence, compensated heart lesions, hypertension, rheumatism, diabetes, anemia, etc. Homelike atmosphere. No bed-ridden contagious or mental cases.

ROBERT SCHULMAN, M.D., Medical Director

Telephone—MORRISTOWN 3269

THE DR. C. O. SAHLER SANITARIUM

Pleasantly located in the suburbs of the charming city of Kingston. Within easy access of New York, and with all modern facilities for treatment of selected cases of Organic and Functional Disorders of the nervous system and invalidism from any cause. Average price of rooms—without bath—\$5.00 per day including ordinary medical and nursing attention. No cases of insanity or communicable diseases accepted. Booklet on request. Telephone Kingston 948. Raymond S. Crispell, M. D., Medical Director.
Kingston-on-Hudson, New York

THE DOWN-TOWN PHYSICIAN'S PHYSIOTHERAPEUTIC SERVICE

renders all kinds of prescribed treatments in Physio-Therapy (incl Colonic Irrigation, Baking and Massage) to patients of the downtown district. All treatments given must be authorized by a physician

"The Woman's Auxiliary, which as you remember, originated in Texas, has become an important national force. It is utilized by medical societies in carrying the gospel of dependable health measures to the general public, by the encouragement of health programs in the various women's clubs. These club programs, which likewise originated in Texas, have grown in number and influence, and are now established in the women's clubs throughout our country."

The scope and purpose of the Auxiliary is described by Mrs. H. R. Dudgeon, of Waco, President of the Woman's Auxiliary of Texas:

"The Woman's Auxiliary has a splendid opportunity here to act as a public relations committee, assisting the medical profession in making the right kind of educational contact with lay organizations.

"The Woman's Auxiliary has made it an important part of its work to sponsor a wide distribution of *Hygeia*. We try to place it in the waiting rooms of the doctors, where their patients may read it, into the public libraries and especially the school libraries. We are presenting its merits to the clubs and are getting it into the homes whenever opportunity presents.

"We have sponsored radio health talks, as well as health talks before clubs whenever possible. These activities are undertaken, of course, with the approval of the local county medical society and our Advisory Council from the State Medical Association.

"We are doing what we can to aid in the establishment of more accurate birth registration, and we are stressing the importance of yearly health examinations.

"We have in operation a student loan fund, the purpose of which is to help deserving junior and senior medical students. We do not propose to give them this money, but we do let them have it at a very low rate of interest—lower than it can be had elsewhere. This fund has been greatly augmented through the generosity of Mrs. S. C. Red of Houston, who graciously donated to it, for a period of two years, the proceeds from the sale of her book "The Medicine Man in Texas," and the County Auxiliaries have been asked to donate to this fund such amounts as they will each year.

"We have also a Benevolent Memorial fund, which was started by a gift from Mrs. John O. McReynolds, in memory of her mother, to be used to assist widows and children of physicians who are in need.

"Since the woman's vote carries as much weight as any other, it is easy to understand the importance of organization of our Auxiliaries, as a source of political strength and influence in legislative and other public programs, both state and national medical associations."

VENEREAL DISEASE CLINICS IN ALABAMA

The June Journal of the Medical Association of the State of Alabama contains the following article by Dr. D. G. Gill, Director of the Bureau of Venereal Diseases of the State Department of Public Health, describing the standards for venereal disease clinics:

"The State Board of Censors recognizes that the ultimate success of any plan looking to the clinical control of the spread of venereal disease must have, not only the sympathetic support of the medical profession, but also that such support should be enlisted by giving to the members of the profession a voice and financial interest in the execution of such plans. In all public health work conducted in this State, the voice of the profession is now articulate. Inasmuch, however, as these clinics are operated and financed largely by the State Department of Health and are not an integral part of county health units, but often serve more than one county, the Board feels that, while every consideration should be given County Medical Societies in the selection of personnel and in the conduct of these clinics, the final decision as to personnel and policy should rest with this Board. In order to stimulate a keener interest among all members of the profession in this important work, the Board, at its last meeting, in April, adopted the following regulations governing the operation of the free venereal clinics.

"Hereafter, whenever a decision has been reached by a County Medical Society and the State Committee of Public Health that a free venereal clinic is to be established at any point in a county, the following rules shall govern:

"That the members of a County Medical Society, in regular meeting, shall submit to the County Board of Censors the names of one or more members whom they consider suitable and competent to do this particular work.

**Diuresis is recommended
in many forms of
Heart Disease
as an adjunct to other

"That, from the names submitted to the County Board of Censors, it shall recommend to the State Health Officer, the name of one member for the position of venereal clinician.

"That the salary of such clinician, when paid in whole, or in part, by the State, shall be fixed by the State Committee of Public Health.

"That the formulating of rules and regulations governing the operation of such clinics is the responsibility of the State Committee of Public Health."

ADVERTISING AGENT FOR THE CALIFORNIA JOURNAL

The minutes of the January 16 meeting of the Council of the California Medical Association, printed in the February issue of California and Western Medicine, contain the following article in regard to employing an advertising manager for the Journal:

"Doctor Kress, Editor, stated that the southern councilors had met with Mr. Butterworth, an experienced advertising man, who had kindly consented to give his time and advice in the selection of an advertising agent; that Mr. Butterworth stated that he felt that an advertising agent could secure considerable advertising in southern California but that a full-time man was necessary.

"On motion of Dr. Kress, seconded by Dr. Catton, the following resolution was adopted:

"Resolved, That this matter be turned over to the Los Angeles councilors with power to select an advertising representative for southern California; that such employment of such advertising agent be subject to a contract covering the terms, compensation, etc., as may be prepared by this Council upon advice of the general counsel, Mr. Peart."

"Resolved, That the councilors from southern California be authorized to engage an advertising agent on a drawing account not to exceed \$200 per month and not to exceed in the aggregate \$600."

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three cents each for additional words.

WANTED: Salaried Appointments everywhere for Class A physicians. Let us put you in touch with investigated candidates for your opening. No charge to employers. Established 1896. Aznoe Service is National, Superior. Aznoe's National Physicians' Exchange, 30 North Michigan, Chicago.

ARLINGTON, New Jersey, 211 Stewart Av.—Attractive 7-room house; plot 120x103; oil burner; 2-car garage; 8 miles from New York City; 5 minutes' walk from station and bus lines; rent \$100 month or sell, easy terms, at a bargain price. Owner, Box 5, Care N. Y. State Journal of Medicine.

60S, EAST—4 rooms, suitable Doctor; co-operatively owned; for sale; great sacrifice; upkeep \$66.00; owner leaving city.

50S, EAST—Corner, 4 rooms, 2 baths, including large living room, suitable Doctor; building co-operatively owned; rent very reasonable; possession. MURRAY Hill 2-8514. Address: Box 27, Care N. Y. State Journal of Medicine.

MASSEUR OR ATTENDANT—Swedish, wishes position in private or institution. Thorough knowledge Swedish system of massage and medical gymnastics; also colonic therapy. First class references. Willing to go anywhere. Reply, Alfred Nordstrom, 75 Sherwood Place, Greenwich, Conn. Telephone: Greenwich 1775.

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed; in the hilly country one and a half miles from Long Island Sound where the air is tonic. Truly homelike, no institutional appearance. See page xxiii.—*Adv.*

WHAT IS MALTCOA?

Maltco is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

"MALTCOA" ANALYSIS:

Moisture	3.03%
Cocoa Butter	4.42%
Butter Fat56%
Milk Solids not Fat	10.09%
Crude Fiber89%
Cane Sugar	45.07%
Maltose	14.72%
Total Protein	9.87%
Dextrin and Other Carbo- hydrates	7.36%
Mineral Ash	3.99%

100.00%

The ash contains:

Sodium Chloride	0.84%
Iron	0.09%
Calcium Oxide	0.52%
Phosphates as P ₂ O ₅	1.41%
Calories per Pound:	1830

See page xiv.—*Adv.*

HAY FEVER CLINIC

Due to the increased demand of people sensitive to Hay Fever Pollens and allied diseases, the New York Polyclinic Medical School and Hospital has enlarged this department to meet their needs. Clinics are held every morning from nine-thirty to eleven o'clock. See page iv.—*Adv.*

SIMPLIFYING SUMMER INFANT FEEDING PROBLEMS

Vacation travel presents fewer difficulties in caring for infants on S.M.A. Instead of using milk from dairies of unknown standards, the mother feeding S.M.A. is using a food made from milk which her physician knows to be produced under strict sanitary requirements and rigorous inspection.

Refrigeration is unnecessary because individual feedings of powdered S.M.A. may be made up as needed. If the supply runs out, S.M.A. is available virtually everywhere in the United States in prescription pharmacies from Skowhegan to Hollywood. S.M.A. is not a grocery product for adults, but a scientific antirachitic breast milk adaptation designed for infants.

S.M.A. is made to resemble nature's own formula, breast milk, as closely as modern scientific knowledge and laboratory control can accomplish, certainly closer than a trial and error formula. See page xix.—*Adv.*

ANTIPHLOGISTINE

The summer vacation exodus is in full swing and thousands are flocking to country and seaside in search of relaxation and pleasure.

Many vacations, however, are doomed to end unhappily through illness and accident, and physicians will be called upon to treat innumerable traumatic injuries of the muscles, tendon sheaths, bursae and synovial structures about the joints; sprains, abrasions, lacerations, dermatitis caused by poison ivy and other plants, sunburn, etc.

In these cases physicians will find Antiphlogistine one of the most useful and efficient all-round dressings.

In addition to its antiseptic, analgesic and osmotic qualities, Antiphlogistine by stimulating the flow of blood to the parts, favors the absorption of infiltrations, exudations and adhesions.

Injuries resulting in blood and fluid in the various synovial sacs are particularly responsive to Antiphlogistine; and the associated edema and stiffness of a joint, following fracture, are usually much relieved.

Physicians are invited to write for sample and literature. See page ii.—*Adv.*

CHOOSING A HYPNOTIC

Every physician is familiar with several agents from which to choose when called upon to prescribe a sedative for nervousness, hyperthyroidism, menopausal symptoms, neurasthenia, or psychasthenic states, or where the indications point to need for rest and repose.

Since the use of the product prescribed must often be continued over a considerable period it becomes important to select an agent that will accomplish the desired results without effects that are harmful.

Unlike barbital and phenobarbital, Amytal is reported to be completely destroyed in the body. Extensive experimentation is said to have been conducted in a study of the effect of Amytal on the kidneys. Reports show that there was not even microscopic evidence of injury. No known decomposition products of Amytal have been recovered from the urine. By regulating the dose of Amytal, the physician is said to find it easy to produce ambulatory sedation, to quiet the nerves before undergoing trying ordeals, or to produce sound sleep from which the patient will awaken rested and refreshed without depressing after-effects. See page x.—*Adv.*

INFANT FEEDING

The Texas State Journal of Medicine for February, 1932, comments editorially on the growing custom of drug chain organizations to adopt so-called merchandizing methods in handling well-known products, such as infant foods,—referring to the practice that drug stores shall handle only those products whose manufacturers make special concessions to the retailers, and that, in return, drug clerks will push the sale of the preferred products. The people are ready to believe that the clerks know how to prescribe infant foods, but the results of their advice are often deplorable.

There is so much lay feeding of babies now going on, thanks to ill-advised "public education," that sooner or later many of these babies are brought to the pediatrician when they are in pretty bad shape and the frantic mothers do not know what to do about it.

We have been trying for years, and especially during the depression, to keep medical practice in medical hands. We could probably make a good deal more money than we do, were we to go directly to the public with our products. But we believe that our interests are closely linked with those of practicing physicians, and theirs with our own. Mead Johnson & Company will co-operate with the medical profession in the future as in the past. See page xxvi.—*Adv.*

TRAUMATISMS OF THE FRONTAL AND TEMPORAL REGIONS AND THEIR RELATION TO MENINGITIS FROM THE STANDPOINT OF THE GENERAL SURGEON

By WELLS P. EAGLETON, MD, NEWARK, N. J.

Opening the discussion on Cerebral Trauma before the Annual Meeting of the Medical Society of the State of New York, at Syracuse N. Y., June 3, 1931

SURGERY in any injury to the brain or its coverings can accomplish but two things—first, it may relieve compression, second, it may cure sepsis, or, better still, it may prevent infection, that is, meningitis. It can do nothing more. Consequently, from a surgical standpoint the questions in every cerebral injury are first, is compression present? second, is sepsis apt to occur?

In the automobile accidents of today about 10 per cent die as the result of brain laceration with its associated extensive intracerebral hemorrhage. They become unconscious immediately upon the receipt of the injury and never regain consciousness. They die as the direct result of damage to the cerebral tissue, although they may live for several days. In brain laceration, surgery but shortens the few hours or days that the patient otherwise may live, for any surgery simply adds a further trauma to the already over-damaged brain.

Barring cases of brain laceration, in skull fracture it is now a recognized duty immediately to convert a compound linear or depressed fracture into a simple fracture through debridement (the excision of the soft parts of the wound, the removal of all loose fragments of bone, the elevation of any bony depression, and finally the tight closure of the skin without drainage). For so sensitive to infection are the meninges that a large proportion of compound skull fractures with a dural tear that are treated by drainage end in meningitis.

Rule I. Every compound fracture should be converted into a simple fracture—it should not be drained.

But I have elected to discuss simple linear fractures of two areas of the head—the frontal and temporal regions—because these areas possess peculiar anatomical and physiological properties that permit of certain injuries which do

not make the patient seriously ill immediately following the trauma, but if improperly treated result fatally in a large proportion of cases. A fatality in such a case, then, is a complication of what in reality is an unimportant injury. The questions are—how are these cases to be recognized and when and how treated?

Types of Cases To Be Discussed

First type, a patient has an injury to his frontal region—he has bleeding from his nose, a black eye, he is dazed or unconscious for a short time and then gradually regains consciousness, the x-ray reveals a linear undepressed fracture through his frontal bone. On arrival at the hospital nothing surgical is done because, the immediate effect of the injury having passed, the patient is apparently normal. Suddenly, a week, perhaps three weeks or even several months after the injury, he has a severe headache, the temperature rises and he rapidly becomes unconscious. A lumbar puncture now shows a purulent meningitis. In a few days he dies. This occurs because his recognized compound fracture—for with bleeding from the nose the fracture entered the base—with an injury to the brain or its coverings had not been converted into a simple fracture.

Second type. A man is struck on the temporal region. He is unconscious but soon regains consciousness. He has great dizziness, vomits continuously and has marked nystagmus. Blood comes from his ear, this is followed by a flow of cerebrospinal fluid. He manifestly has a compound fracture of the base which has perforated the dura. Immediately following the accident and for the next day or two the patient looks very ill but in a few days all symptoms disappear and outside of total deafness of one ear and possibly an annoying buzzing he is well and so remains.

There are thus two types of linear fracture of the base of the skull—in one the patient is immediately following the injury desperately ill with outstanding cerebral symptoms but there is a rapid and prominent recovery; in the other, he has slight or no cerebral symptoms at the beginning but later death occurs from sudden and unexpected meningitis.

Surgical Anatomy and Physiological Consideration in Fractures of the Frontal and Temporal Regions

To understand traumatic lesions we must appreciate the physiological and anatomical differences in the two regions—both of the skull and of the brain. For all anatomical differences have a physiological basis and these anatomical and physiological differences supply the cerebral and peripheral symptoms and should dictate the character of our surgery.

The frontal and temporal areas of the head are anatomically different because they serve different purposes in the evolution of life.

The frontal bony region contains a mechanism, the nose with its accessory sinuses. The mucous membrane of the nose was evolved by life to prevent infection of the brain. It was present while life was still in the water. So efficient is this mechanism that, although the mucous membrane of the nose is constantly the seat of bacteria, brought to it from the air; and although the nose is separated from the brain by but a thin layer of bone with many holes in it—the cribriform plate—still the normal mucous membrane mechanism prevents infection of the meninges. It is only when this protective mechanism is broken down by trauma or disease that we have cerebral sepsis, that is, meningitis, from the nose. On the other hand, the temporal region is preserved by life to protect the brain from trauma. This protection is because the temporal region contains the ear—the organ of hearing—the most delicate of all life's mechanisms and the most important of life's attributes in its evolution from the material into the spiritual. From hearing speech was evolved. Hearing is a late addition in life's evolution.

Fishes do not hear as we understand hearing, but some fishes perceive sound—the same as man hears a roar as the train "thunders" through a tunnel.

But after life crawled out of the water on to the land there developed a mechanism for the reception of grades of sound—the cochlear apparatus. At the same time the central nervous system was undergoing a consummate expansion. In land-confined vertebrate animals, smell is the important sense—the rabbits, the rodents, the deer—they all recognize their food, their mates, their enemies, chiefly by smell assisted by hearing. In them the cerebral area of the sense of

smell is so important that it composes a large part of the brain. But when life took to the trees the cerebral part of the smell area diminished, and the visual area increased. So that in the primates the olfactory area is insignificant in size compared to the rest of the brain; but in the mantle, the neopallium, which grows over the brain from behind, the visual area is large; and with the growth of the mantle forward there appears greater and greater intelligence.

And at last, in man, out of the complicated peripheral mechanism of hearing—the auditory apparatus—adapted to receive different grades of sound; and its cerebral connections in the temporal cortex of the brain—for the analyzing of pitch and tone—there came speech.

Speech was made possible by the evolution of the peripheral cochlea for the reception of different tones and by an addition to the cerebral cortex of a specific area. The speech area is placed between the frontal and parietal lobes and is covered by the squamous portion of the temporal bone—the thinnest part of the skull and where the sutures of the skull are the last to unite. For it is the late closure of the sutures that gives man an advantage over the animal. It allows his central nervous tissue to continue to develop long after birth. If a child does not hear, it does not talk, and a child does not begin to talk until it is two years old.

The temporal bony area of the skull because of its thinness and because of its unclosed suture would be especially liable to injury were it not protected by a flying buttress of bone, the zygomatic process.

Again, injury to the brain behind the thin squama presents few symptoms, for the temporal lobe is a silent area outside the cortical area for speech on the left side, so there may be extensive damage to the temporosphenoidal lobe from direct trauma or by contrecoup laceration without symptoms.

Consequently, from a physiological standpoint we find: (1) the frontal region especially adapted to the prevention of infection from attacking the brain; and (2) the temporal region, especially adapted to prevent trauma from injuring the brain.

If the frontal bony region is adapted to the control of infection, then an intracranial complication from nasal sinus suppuration should be very uncommon, and such is the case, for although suppuration of the frontal and ethmoidal sinuses is almost universally present in people living in rapidly changing temperatures, intracranial complications from suppuration in the nose occur but seldom. There is only one cerebral complication—brain abscess, meningitis or venous sinus thrombosis—from suppurative disease of a nasal sinus to about forty from discharging ears.

On the other hand, linear fractures which extend through the nasal region into the skull with a *tear in the dura* have a mortality of 25 per cent; while linear fractures of the temporal region in which the dura is also injured (for there is a flow of cerebrospinal fluid from the ear), have a mortality of only 8 per cent. So in these two regions, the nose and the ear, we must be able to diagnose which are dangerous fractures.

Fractures of the Frontal Region

In all simple linear or depressed fractures of the frontal region (that is, without rupture of the skin) it is of great clinical importance to determine whether the fracture is (1) external to the sinuses or (2) through a sinus. Any fracture which passes through the sinuses is a dangerous fracture *provided the dura is torn*, because a fracture which extends from a frontal sinus through the dura and into the brain has a direct communication with the outer world. It is in reality a compound fracture but the communication with the external air is hidden; it is inside the nose.

A fracture through a nasal sinus with a *tear in the dura in those regions in which the dura can be stripped from the bone*, such as the posterior surface of the frontal sinus, may cause meningitis because the mucous membrane of the nose is a low grade, rapidly proliferating tissue, and if there be a tear in the dura, mucous membrane from the nose may grow into the brain before the fracture becomes united. Later if the mucous membrane of the nose becomes infected by a cold, the bacteria may pass from the nose, through the crack, through the dura and into the arachnoid by direct continuity of tissue infection.

With cracks through the cribriform plate this does not happen. In this region the dura cannot be separated from the bone; the dura and the bone are one structure; and here again, at the roof of the nose, the mucous membrane is a highly specialized sense epithelium, which does not proliferate rapidly. Fractures through the cribriform plate do not cause meningitis, excepting in cases of a wide defect between the fragments, or from displacement of pieces of bone through the dura.

I have said that 25 per cent of the patients with fracture of the posterior wall of the frontal sinus with a tear in the dura die of meningitis. How can these dangerous fractures be recognized and how treated so that meningitis may be prevented? This must be done while the patient is still in good condition.

Linear fractures through the sinuses produce (a) bleeding from the nose, and (b) black eye. The position of the fracture and whether it involves the posterior wall of the sinus may be seen in the (c) x-ray; or its position may be suspected by (d) the presence of exophthalmus; if the fracture goes through the cavernous sinus. In the latter cases there is apt to be a bruit upon

listening to the head. This bruit is sometimes present without exophthalmus. Consequently, auscultation of the head should be performed routinely in every fracture of the frontal region. Again, if the fracture goes through the sella turcica we may have (e) pressure on the optic nerve, in which case there will be visual or visual field disturbances. Therefore, in all frontal fractures we should test the vision and in fractures of the frontal or temporal regions we should map out the visual field. But in the absence of all localizing symptoms what we want to know is whether there is a tear in the dura or not. (f) This a lumbar puncture may decide by showing whether there is blood in the spinal fluid.² If there be no blood the dura probably is not torn.

Rule II. All fractures of the inner table of the frontal sinus with a tear in the dura should be widely opened and a layer of skin or fascia lata tucked in, thus short-circuiting the nose from the pia-arachnoid by walling off the sinus, so as to prevent a later infection from colds. If the patient has not been operated upon immediately following the accident, and he later develops headache and fever, operation is imperative, and the better his condition the greater is the indication for operation, for if the infected fluid is early evacuated the meningeal inflammation may be stopped.⁴

Simple Linear Fractures of the Temporal Region

Simple linear fractures of the temporal region from a diagnostic and surgical standpoint should be divided into (1) fractures through the squamosal portion and (2) those through the petrous portion of the temporal bone.

Linear fractures through the squamosa without severe symptoms are especially important because of the possibility of injury to the middle meningeal artery.

The middle meningeal artery in its upper part is adherent to the dura, and in its lower part is within the bone; consequently it cannot retract, and so stop bleeding from a tear in its wall. The result is that a middle meningeal artery, torn by a linear fracture, may slowly bleed over and over again, and ultimately, an extradural clot may cause cerebral compression; and this hours after the receipt of the injury.

Rule III. All fractures of the temporal region followed by an interval of consciousness should be operated upon if the patient later becomes unconscious, because, if there has been a free interval, the compression which causes the coma, in part at least, must be from an extradural clot.

A subdural hemorrhage—pachymeningitis hemorrhagica interna—may be present if the free interval has been of days' duration. All surgeons know that patients with extradural hemorrhages from fractures through the middle meningeal artery—in which the patient after receiving a blow

is conscious and then lapses into unconsciousness—die suddenly of medullary compression.

How can we be warned that respiratory paralysis is imminent?

Rule IV. If there be a suspicion that there is a fracture of the temporal region and the patient has had a conscious period *no matter how short*, take his blood pressure and count his pulse at least every half hour. If the systolic blood pressure persistently rises and the diastolic drops, that is, an increasing pulse pressure develops—which is a sign of the medulla's call for blood—and especially if the pulse becomes slower, signifying general brain compression; respiratory failure will occur if the increasing intracranial pressure is not promptly relieved.

But it is asked—what about brain laceration with its associated hemorrhages into the brain substance, which is the cause of death in the majority of cases of cerebral traumas that end fatally? The patients do not have a conscious interval. In brain laceration which is sufficient to cause compression the patient is immediately unconscious and remains so, although I have seen one case of cortical laceration with subdural space hemorrhage from brain laceration in which the patient did not become unconscious for several hours.

The practical thing in all fractures of the anterior portion of the temporal region is to ascertain (1) if the fracture is in the region of the middle meningeal; and (2) whether there has been an interval of consciousness.

Rule V. In all cases of cerebral trauma in which the patient is unconscious find out if there has been a free interval.

Cases of injury to the temporal region without fracture in which the patient is unconscious for a few minutes and then regains consciousness.

In such a case the pathologic condition is either (1) concussion of the brain or (2) subdural space hemorrhage.

Concussion: What is concussion?

It is caused by multiple punctate hemorrhages into the perivascular spaces of the brain.^{5, 6} Diffuse punctate hemorrhages do not cause cerebral compression. If the hemorrhages are extensive enough and especially if they involve the basal ganglia, the patient may die. He never regains consciousness.

Ordinary concussion—in which consciousness is lost for a minute or two—does not kill the patient but still it is a serious condition as regards his future comfort and well being. For if he is allowed to exert himself for some time after the accident, later he is apt to develop headache and vertigo, from which he may never recover. In all of my cases of brain concussion in which consciousness has been lost if only for a few minutes the patients are confined to bed for at least a month. During this time the slightest appearance

of compression or brain irritation—headache, slow pulse, etc.—calls for lumbar puncture (to remove the irritating blood from the cerebrospinal system) and dehydration (the administration of magnesium sulphate and intravenous injections of glucose). The restoration of the dynamical equilibrium between the hemic pressure, the cerebrospinal dialyzing, and the intercellular nutritional systems is a delicate physiological problem once the normal equilibrium has been disturbed by trauma.

Blood in the cerebrospinal fluid system over the cortex causes cortical irritation, headache and even delirium. Blood in the fluid of the base causes stiff neck.

Rule VI. In cerebral trauma, headache or delirium calls for lumbar or occipito-atloid punctures to remove the irritating blood as well as to reduce the pressure.

How can the otologist be of assistance in determining whether or not there was a cerebral trauma in those patients who weeks after the accident claim to suffer from headache and dizziness without other neurological symptoms, and in whom a radiogram fails to reveal a skull fracture? By demonstrating whether there is a reduction of at least 50 per cent in the duration of the induced nystagmus after rotating the patient.^{7, 8}

Rule VII. In all cases of doubt as to whether the brain has been injured have the patient's vestibular apparatus carefully examined, but not until at least eight weeks after the accident.

Subdural Space Hemorrhage

There is a group of cases of injury to the temporoparietal region—subdural space hemorrhages—that show delayed signs of local compression—papilloedema, ocular paralysis, headache and vomiting without a skull fracture; but the spinal fluid is yellowish from old blood.

Rule VIII. If following a trivial injury of the head the patient continues to have headache, make repeated ophthalmoscopic examinations and search for evidences of blood in the spinal fluid.

In fractures that go through the petrous portion of the temporal bone—that is, the posterior part of the temporal region—how are the dangerous ones to be recognized?

If the fracture passes through the labyrinth the patient is totally deaf on that side, and there are nystagmus and bleeding or an escape of cerebrospinal fluid from the ear. If there is bleeding but the patient still hears, the fracture is not apt to cause meningitis.

Rule IX. Ascertain if there is any hearing in the affected ear, for if there is hearing the prognosis is good.

Again, in all cases of linear fracture of the petrous portion even with total deafness, nystagmus and vomiting and an escape of fluid but without a rise of temperature, or pain in the head,

nothing surgical should be done. For experience shows that linear fractures of the base through the labyrinth without brain laceration develop meningitis only in 8 per cent of the cases.

All surgeons now appreciate the danger from syringing the ear in case of bleeding, that it may light up a meningitis.

In linear fractures of the petrous portion what are the signs which should warn the surgeon that the suppuration is advancing toward the meninges?

Rule X. If following a fracture of the petrous bone, fever and headache appear (especially in the presence of a suppurating ear) operate at once. Expose the line of fracture along the petrous bone at least beyond the middle ear and the eustachian tube, for meningitis has developed and it must be combated.

Conclusions

This paper would emphasize

(1) The limitation of surgery in all cerebral injuries whether accompanied by a skull fracture or not, to (a) the prevention of sepsis and (b) the relief of compression.

(2) The diagnostic importance of consciousness and unconsciousness in injuries of the frontal and temporal bony regions. If unconsciousness is present the importance of ascertaining whether there has been a free interval even if it was only a very short one.

(3) How to diagnose clinically, while the patient is in good condition, the deceptive cases of linear fracture of the frontal bone that are apt to develop meningitis.

(4) The conversion of compound but hidden fractures of the frontal sinus with a tear in the dura into simple fractures.

(5) The value of lumbar puncture for the removal of blood from the cerebrospinal fluid in injuries of the brain.

(6) The value of the turning reactions in determining whether or not the brain has been damaged by an apparently trivial head injury.

(7) When to operate in fractures of the petrous bone.

THE SUB-ERYTHEMA METHOD IN ULTRA-VIOLET RADIATION

By JOSEPH ECHTMAN, M D, NEW YORK, N Y.

From the Physical Therapy Service of the German Polyclinic New York City

SINCE the ultra violet rays became popular and in great use by medical practitioners, lay practitioners, and laymen their misuses and abuses claimed a number of victims more so than it is really known.

The main cause responsible for the mischief is that the only warning which ultra-violet radiation is always "sensing" to the patient—the erythema—is not taken into consideration or is misinterpreted. It is however in the erythema where the danger is hidden.

I could cite many instances of great harm done to the healthy and the sick by ultra-violet burns, but for lack of space I shall limit myself to the following one which prompted me to write this paper.

We have here a case of a tragic end of a

young woman (age 26) treated somewhere with ultra-violet radiation for six months. About that time certain symptoms, among which dyspnea was the most prominent one, became so alarming, that they compelled her to discontinue the treatments and look for help and advice. An accompanying condition was a chronic gc arthritis of the left knee which was also a source of great worry to the patient, and I had a chance to see her in consultation in my clinic.

Of great interest to me was the following part of her history. She stated that she was a mother of two children and had always felt well, except for the arthritis for which she was treated by the same operator who irradiated her with the ultra-violet light. She em-

phasized that she had felt constitutionally perfectly well when the radiations were started, but later on she began to experience palpitation, dyspnea, especially on exertion, and this condition grew rapidly worse. She finished her story with the words, "and how he used to BURN me! . . ." She especially accented the word "burn" uttering it with a pleasant smile which denoted satisfaction and imparted to the listener the impression that the patient and operator were heartily sure that the greater the burning the greater the benefit derived from the treatment. She presented an ideal picture of cardiac decompensation. In addition she was an advanced nephritic. I learned later that she died within two months after this consultation. There was no doubt in my mind that her death was at least hastened (*) by the ultra-violet erythemas. Six months of repeated burning of the skin created all those agents, known and unknown to us, (as we still are ignorant of the mysterious influence of these rays upon the animal body) that caused the damage to her heart and kidneys, manifested by the alarming symptoms which compelled her to discontinue the ultra-violet treatments and look for relief, but it was too late. . . .

It is therefore the aim of this paper to point out a simple and safe method for the use of Quartz Light, and to show that the skin burn, the erythema, is dangerous and is a total unnecessary item in the treatment of diseases where general body radiation is considered of benefit. This method discards the erythema entirely, wherefore the author names it the Sub-Erythema Method.

There are four main factors which are responsible for the injurious effects of ultra-violet radiation and the resulting erythemas. These are: penetration, energy, skin injury, and liberation of histamine.

Penetration. It was always considered that the penetration of the ultra-violet rays is very inappreciable. It was thought that these short rays, having a wave length of about 2900 A.U. do not penetrate even all the layers of the skin. The experiments however, of Gassul and Levy have proven that they do penetrate considerably. These authors, as quoted by Laurens¹, "marshal considerable evidence in favor of their view that ultra-violet radiation has considerably more penetrating power than is usually accorded it." They irradiated mice with a Hg. Quartz Lamp for varying periods of time up to a certain number of hours and then killed them. Upon examination they found severe pathological changes in the lungs, spleen, liver, kidneys

and blood vessels. Irradiation with red light produced no demonstrable changes in the viscera. They regarded this as proof of direct deep action on the part of the ultra-violet on the internal organs and blood vessels.

Parallel with the experiments of these authors, the following incident is of interest. Clausen² quotes MacCormack and McCrea reporting the case of a man who fell asleep during a self-administered treatment from a Quartz Lamp. He received an exposure lasting one hour and ten minutes. This overdose was followed by a grave constitutional illness.

Energy. John Bunker,³ Professor of Biology and Physiology of the Mass. Institute of Technology, sounding his warning with regard to the abuse of ultra-violet radiation says, "Ultra-Violet Light is still a mystery. It is mysterious, it carries energy and transmits it to the patient. Ultra-Violet Light is energy, and this energy, at times, is very powerful. This type of energy can, we know, be absorbed by the body. The laws of the behavior of energy in this universe apply to the behavior of energy in the body. It cannot be lost, but most of it must be transformed because obviously there is a limit to its storage. What the transformation may be we do not know."

So little is written on the possible damage by ultra-violet energy that there is hardly a case on record to cite for illustration. The following however, may serve as examples of damage due to this energy.

a. Ergosterol is a constituent of the skin and a precursor to Vitamin D. The irradiated ergosterol is the Vitamin D. Application of too much energy in the form of ultra-violet light to ergosterol results in destruction of the Vitamin after its formation. (Bunker. *Ibid.*)

b. Discussing the effect of ultra-violet radiation on the blood, Laurence⁴ says, "of considerable interest is the demonstration that too much, or too frequent, irradiation is definitely harmful. Hobart regards the damage as of double nature, first in the too rapid maturing of the red cells, and by the formation of more reds succeeded by an accelerated storing of reds giving rise eventually to an anemia." The rapidity of the process observed only on too much or too frequent irradiation may be explained as due probably to excess of ultra-violet energy absorbed by the body.

Skin Injury. Actinotherapists differentiate four degrees of actinic ray skin reactions (erythemas). In all these reactions we deal practically with various degrees of injury to the skin. Taking into account the physiologic functions that this organ has to per-

* On the supposition that this patient was a mild cardionephritic at the beginning of the radiations.

form, we may appreciate the importance of its integrity. These functions are protection, sensation, EXCRETION, RESPIRATION and HEAT-REGULATION. The last three are particularly influenced by the ultra-violet erythema, and therefore will be discussed from this point of view.

Excretion It is our knowledge that the skin assists greatly the kidneys in their catabolic process. Injury to a large skin area interferes with this assistance. Repeated injury to the skin means repeatedly overburdening the kidneys. Even a first degree erythema (*) causes injury to the skin. This can be judged from the fact that desquamation, though not easily visible, is, nevertheless, present in this degree of erythema, and, to quote Lewis⁵, "desquamation is a sequel to almost all forms of injury" since it may be read legitimately as the removal of the husks of killed cells. Consequently a first degree erythema may interfere with proper excretion.

Respiration The skin excretes carbon dioxide and absorbs oxygen utilized by the body. This cutaneous respiration, as mentioned by Bardeen⁶, equals to about 1/25 of the total normal respiration of the body. When repeatedly injured by erythemas, the skin shares poorly or not at all in the process of respiratory function. This leads to overwork in the lungs and consequent weakening of the latter. We thus find a solution to the strange phenomenon repeatedly observed that ultra violet radiation (erythemas) has caused the mischievous awakening of dormant pulmonary T B foci which resulted in the destruction of this organ.

Heat Regulation This function explains why ultra-violet radiation is contraindicated in cases with fever. The injury to the skin caused by the erythema hinders this function.

Histamine This substance plays a great (or probably the greatest) role in the causation of injury to the body by erythemas.

Histamine is a highly toxic substance. When in sufficient amount in the body, it is capable of producing shock. It is found in the muscles and viscera, and probably in every organ and tissue of the body, and is released from the viscera either by irritation to the latter, e.g. when the liver or intestines are roughly handled by the surgeon, or by injury to the skin, e.g. by an ultra-violet erythema.

According to Lewis⁷, histamine, or substances behaving like histamine, designated by him collectively as the H-substance, are liberated by trauma to the skin or during a

dermatitis caused by various agents, such as scalds, fire, ultra-violet light, etc. Again, the H-substance in the burnt skin may, by way of circulation, reach the viscera, and thus become a constant source of toxin to the body. Simultaneously the dermatitis causes, probably by some reflex action, a release of histamine in the viscera which results in damage to the latter*. Furthermore there seems to exist a definite physiologic relation between the injury produced in the skin (by erythemas) and resulting pathological changes in the viscera. Not only are these changes caused by severe skin burns, but they may follow even mild erythemas.

Bardeen⁸, who studied a number of cases that suffered superficial burns, states, "Death has often followed burns so superficial as to give rise merely to an erythema. It is clear from this latter class of cases, at least, that alterations in the internal organs may follow the burning of the skin which cannot be accounted for on the supposition that they are directly caused by the heat. Thus arises the question as to the nature of the physiologic relations between the lesions produced in the skin and the resulting constitutional effect."

Now,** "it remains to determine to what extent the response (injury) to ultra-violet light is comparable to this more immediate response" (burns by fire, scald, etc.). But the experiments of Lewis⁹ have shown that "the ultra-violet reaction is built up of precisely the same components as is the more speedy response to other forms of injury" (by fire, scald, etc.).

From these authoritative statements it seems logical to conclude that an extensive ultra violet erythema, even of a first degree nature, may be detrimental to some patients at least. For absolute safety therefore to every patient, it were best, using ultra violet general body radiation, to avoid the erythema entirely by employing the sub erythema method (described below).

Apprehension, however, exists in the mind of the physician and public of America and Europe*** that if the patient is not "well sunburnt" by an ultra-violet exposure the treatment is worthless. In order to assure the physician that the sub erythema method is

* Titus, discussing a paper on ultra violet radiation read by Edgar Mayer of Saranac Lake at the New York Academy of Medicine (1931), cited a case of gastric hemorrhage caused by over exposure to quartz light due to liberation of histamine.

** Using the words of Lewis.

*** Rosewarne of London in his book on Actinotherapy page 94 relates that eosin which produces a strong sensitizing effect relatively to ultra violet rays was at one time much used in the hospitals of the City of Berlin (after the war when the demand for ultra violet rays to reduce the length of administration of eosin in the treatment of erythema, the index of proper exposure as accepted by the physicians and the public.

* A first degree erythema is characterized by (a) the pink-which is visible by good light, and (b) exfoliation—which does follow, though not easily visible.

reliable, the following cases may serve as worthy illustrations.

Case 1: A male patient, age 26, presented symptoms of intestinal tuberculosis though not confirmed by X-ray. The lungs and sputum were negative. Meanwhile an ischio-rectal abscess, for which he was operated upon, made its appearance. Due to frequent hemorrhagic diarrheas he developed a secondary anemia with hemoglobin of 45 and red blood cell count to $2\frac{1}{2}$ millions. A blood transfusion was deemed necessary by his physicians, but for some reason it could not be carried out, and they referred him to me for ultra-violet radiation.

The patient had a ghastly look and was emaciated, as he had lost 48 pounds since he had taken ill. Pulse 120 per minute. Temperature by mouth was 102.8. (It was not taken rectally because of the wound from the operation for the abscess, which was healing very poorly.) He received 80 exposures to quartz light (given almost daily). Result: The temperature and pulse went down by lysis. The blood count and hemoglobin became normal. The ischio-rectal wound was healing rapidly. The stools gradually became normal in every respect. His weight increased and toward the end of the treatments he weighed more than before he took ill. His body was mildly tanned in spite of the fact that not one exposure was accompanied by a discernible erythema.

The only medication used was calcium which, as pointed out by the author elsewhere,^{10, 11} may be of benefit in tubercular and other diseases, especially in conjunction with ultra-violet radiation.

Case 2: A widow of 43 years who had worked as a saleslady in a store for the past eighteen years, contracted pulmonary tuberculosis. She was treated for over a year by country rest and medication, but her condition became progressively worse. Almost semi-ambulant she came under our care. Chief complaint: She was unable to utilize food. A small quantity of the latter, in liquid or solid form, would cause distressing cough and vomiting. She lost considerable weight. Her usual weight being 104 pounds, her weight then was 76 pounds. The pulse was 110. The temperature was 101 degrees. There was dullness and sibilant r  ls at both apices. Sputum was negative, X-ray positive. Diagnosis: Active apical tuberculosis of both lungs. The gastric disturbance was of reflex origin. She received exposures to quartz light for a period of ten months. Medications consisted of: Calcium salts, dram doses of Spiritus Frumenti (with the milk) which was of good service, and hypodermic injections of Sod. Cacodilate.

Result: the clinical symptoms disappeared and the patient regained her usual weight.

Modus Operandi. The operator should determine the time necessary to produce a first degree erythema at a distance of 36 inches from the burner to the patient. This is known to every physician who uses an ultra-violet lamp. Special appliances are also sold on the market for this purpose, or the method described in books on Actinotherapy, such as Rosewarne's,* Sampson's,** etc., may be advantageously utilized.

Having found the proper time, expose the patient at the first treatment for $\frac{2}{3}$ and increase each subsequent treatment by $\frac{1}{3}$ of that time. The increase is continued until the patient receives 12 minutes on each side, front and back, making a total of 24 minutes, this being the maximum time for exposure. The patient is instructed to examine his body 6-8 hours after a treatment and note the presence of erythema. If the latter is reported (which will always be negligible) the time of exposure for the next two subsequent treatments is not increased. Then continue as before.

This method, because of its harmlessness, permits ultra-violet radiation to be administered without exception in all morbid conditions (where this treatment is useful) even if the latter are accompanied by such symptoms as fever and hemoptitis, manifestations universally recognized as contraindications to ultra-violet radiation. The interval between treatments evidently may be shortened so that more exposures per week can be received by the patient.

In spite of the fact that no visible erythema is produced by this method, nevertheless, some tanning of the patient's skin is noticed after a sufficient number of exposures. Though the author does not consider this tanning (pigmentation) of therapeutic value, for the sake however of the reader, some authoritative opinions of pro and contra on the subject in question will be mentioned.

The importance of the tanning (pigmentation) produced by ultra-violet radiation has been discussed by many authors, such as Clark, Laurens, Jungling, Hausser, Vahle, etc. The rays that bring about pigmentation must lie between the limits of 290-330 au. From a clinical standpoint the theories as to the therapeutic value of pigmentation have been expressed in two ways.

1. That the formation of pigment has a positive value, and is a sine qua non of cure. Bernhard, and Rollier to a large extent, based their prognosis on the production or non-production of pigmentation in the patient's skin. Rollier

* A textbook on Actinotherapy, Mosby & Co., 1928, page 128

** Practice of Physical Therapy, Mosby & Co., 1926, page 244

is convinced that patients undergoing the sun cure who do not pigment readily do less well than those who do, but many others have not found this correlation between pigmentation and light effect, the amount of pigment at most serving as an index of the reaction of the body to the radiation.

2. That the formation of pigment in the skin is of negative or doubtful value. This view has been expressed by Finsen, Reyn, Peacock, and Mayer, and these writers aim at keeping the skin of their patients sensitive to light by avoiding a heavy pigmentation. (Laurens. *Physiological Effect of Radiation*. *Physiological Reviews*, Volume VIII, No. 1, page 76, January, 1928.)

I believe that pigmentation may be looked upon as a protective substance which appears when the body is constantly or too often exposed to rays possessing an injurious element.

Home¹² came to this conclusion after he performed some experiments on his own skin while being in the tropics. He states that the black skin of the negro living in the tropics is his protection against the scorching power of the sun's rays. . . . The Wise Providence has given extraordinary provision to the negro for the defense of his skin while living within that zone. For, the power of the sun's rays

to scorch is destroyed when applied to a black surface.

In conclusion, the author wishes to mention certain substances which when administered to the patient act as sensitizers to ultra-violet rays. These are: quinine (a very powerful sensitizer), mercury, buckwheat, iodine, iron, glandular extracts, eosin, hematoperphyrine (a purple substance, a derivative of hemoglobin. Some individuals have in their body fluids small quantities of this substance, rendering them especially sensitive to light treatments. Bunker, Lorand and others). It is important to inquire of the patient, before radiation is started, whether he is receiving any of these substances.

SUMMARY

The writer aims to impress upon those who employ the mercury quartz lamp as a therapeutic modality that burning of the skin is dangerous, that death lurks in the erythema, which is totally unnecessary in the treatment of diseases where general body radiation is considered of benefit. Cases are cited showing that patients with apparently poor prognosis were treated by ultra-violet radiation, avoiding the erythema entirely, with desirable results. The author calls this form of radiation the sub-erythema method.

OBSERVATIONS ON THE TREATMENT OF ACUTE GONORRHEAL URETHRITIS

By MEYER M. MELICOW, M.D., NEW YORK, N. Y.

From the Urological Department, College of Physicians and Surgeons, Columbia University.

BEFORE one can treat gonorrhea intelligently, one must know the salient characteristics of the gonococcus, the pathology it excites, and the actual effect of our remedies on parasite and host.

The Gonococcus.—In the test tube the gonococcus is a rather delicate organism. It dies when

it dries. Heat, sunlight, x-ray, and ultra-violet ray kill it. Cold inhibits it. Any antiseptic, even in great dilution, either kills or inhibits it. Mild alkalinity is inimical to it.

Gonorrheal Urethritis.—Within the human urethra, the gonococcus becomes virile, is unaffected by x-ray or violet-ray; it is inhibited but

not killed by heat, and can resist chemicals to a remarkable degree.

Thirty-six hours after contamination the interstices between the simple columnar cells of the affected part of the urethra are already occupied by gonococci. Thereafter they quickly penetrate into the submucosa; in which, sheltered by the overlying epithelial layer, they strike root and multiply rapidly. The presence of these foreign bodies or their exo- or endotoxins, causes a severe inflammatory reaction. There is a dilatation of blood vessels, exudation of serum; and a local mobilization of phagocytes. The involved mucosa and meatus becomes red and swollen. This is the Cellulitis Stage, and lasts for 1 to 4 days.

The battle begins. Phagocytes apparently ingest diplococci, and fully laden, pseudopode to the surface. Here and there injured epithelial cells die and are shed together with the leucocytes. A discharge appears which gradually becomes frankly purulent. The flow lasts for 6 to 8 weeks.

The fight is biologically won when gonococci are no longer present. The inflammation subsides, resolution occurs; but injured cells continue to be desquamated until a line of demarkation is formed followed by healing with epithelium of the squamous type. This period is characterized by a morning drop of mucus, and by shreds in clear urine.

There are thus in addition to the incubation period, three stages in an uncomplicated case of gonorrheal urethritis: 1—the stage of cellulitis; 2—the stage of pus, and 3—the stage of resolution. Furthermore, while a real biologic immunity against the gonococcus is apparently not established, nevertheless it seems that gonorrhea is a self-limited disease. There is a tendency to get well; and the cure is apparently affected by a "shaking off" of the invader, and replacing the delicate columnar epithelial lining by the more mechanically resistant barrier of squamous epithelium.

Treatment of Simple Gonorrheal Urethritis:—Keeping in mind the all-important fact that we have no cure for gonorrhea, and also that uncomplicated gonorrheal urethritis has a tendency to be self-limited, it should be the aim of the physician to guard his patients against the development of complications. This he can usually accomplish by giving him proper general care, and desisting from the too frequent and too forceful use of local medications which irritate and damage the mucosa.

The following is an outline of the procedures which the writer has instituted over a period of three years with satisfactory results and with a minimum of complications:

1. General Care.

Every patient receives a copy of the instructions printed as follows:

GENERAL DIRECTIONS

1. Avoid physical strain; tennis, running, jumping, bicycle riding, swimming and diving, too active gymnastic exercises, horseback riding, too much driving, lifting heavy bundles.
2. Plenty of rest, but also plenty of fresh air and sunlight.
3. Avoid late hours, salacious shows, mushy movies, etc.
4. Wash frequently, especially hands. Avoid touching eyes.
5. Do not allow your bladder to become overdistended, empty it as soon as the impulse to urinate arises.

DIET

1. FLUIDS: A glass of water every hour, but not after 7 P. M. May also drink vichy, milk, weak tea, weak coffee (not at night), fermented milks, malted milks. Soups and broths are allowed without spices. Avoid liquors of all sorts.
2. FRUITS: Cooked fruits are preferable to raw fruits.
3. VEGETABLES: All except tomatoes, asparagus, cauliflower, cabbage. No dressings.
4. MEATS: Eat moderately, but need not restrict.
5. STARCHY FOODS: May eat bread, toast, etc. Avoid overeating. Avoid pastries. May eat cereals.
6. SPICES: Avoid all spices and seasoning (vinegar, pepper, mustard, horse-radish, ketchup).
7. SMOKING: Smoking is not prohibited, but do not over-do it.

2. Local Care.

A daily instillation of a mild medication, for cleansing purposes is helpful. It is better for the physician himself to do this as most patients do not know how to properly treat themselves and are apt to contaminate their urethra with secondary organisms. Four to six cc. of the *warm* reagent (either sterile saline, boric acid solution, 5% argyrol, 1:5000 acriflavine or 1:5000 potassium permanganate solution etc.) injected slowly and gently by means of a glass, smooth-tipped syringe, with rubber bulb, is the method of choice. The injection is repeated several times at one sitting, the patient retaining the last one for several minutes. The gravity method and the Janet Irrigator have been discontinued. "Burning" is undesirable, and a warning that the medication is too strong. The use of a cotton plug at the meatus has been condemned because the discharge is thereby held back. A sanitary or "gonorrhea bag," changed daily is better and serves, when inspected regularly as an index of the progress of the purulent stage. Forcing fluids and alkalis are

important measures. There seems to be no beneficial effect from the internal use of methylene blue, hexamethylamine hexyresorcinol, or the sandalwood oils, upon either the symptoms or duration of the disease. Their overuse is often accompanied by urgency, and at times hematuria.

When the discharge becomes mucoid and microscopically shows fewer leucocytes and gonococci, and an increased number of epithelial cells, the stage of resolution is reached. The instillation of the medications noted above is either discontinued or replaced by astringents such as 1:10,000 silver nitrate solution or 1:500 zinc sulphate solution. It is unwise to increase the strength of the medication when the mucoid discharge persists, because a chemical urethritis may follow and the discharge becomes purulent once again. This vicious circle happens frequently, the patient loses confidence, goes elsewhere, only to have something similar done to him. The shedding of dead epithelium manifested by the presence of shreds in a clear urine, is also an expected sequel, just as the desquamation of the skin after scarlatina, and one cannot inhibit either. Heroic measures to eradicate a mucoid discharge or shred are not only unsuccessful, but at times disastrous. Patients should be taught that a non-gonococcus containing drop of mucus or shred following an uncomplicated attack of gonorrheal urethritis, is to be expected. They should be discouraged from repeatedly gazing at their urines, and of the habit of milking the urethra to express a possible discharge.

Complications.—It is the development of complications through involvement of the crypts, ducts, lacunae and glands that line the urethra which prolong the infection indefinitely and lay the foundation for sequelae that often last a life time. The clinical picture also changes. Instead of a mere local irritation whose chief feature is a discharge there appear during the acute stage, constitutional symptoms such as general malaise, anorexia and fever. The chronicity of these conditions is caused by poor drainage, for the gonococci may eventually die out, the orifices of the ducts or their tortuosity, or upward inclination, so interferes with the evacuation of the infected cavities as to make them vulnerable to secondary invaders which may arrive via the blood, lymph, urine or by contiguity, or through injections, or instrumentations (Fig 1).

The development of complications is apparently dependent on any of three important factors:

1 **A Low Individual Resistance.**—While an active or passive immunity to gonorrhea, in the biologic sense, apparently does not exist in the human species, nevertheless as already pointed out, this disease has a tendency to get well. There are, however, patients who, in spite of the best of care, go through a prolonged illness marked by many complications. They lack not only im-

munity, but also an efficient fighting mechanism. It is a factor concerning which we know little, yet is probably of some biologic significance. The tall, thin, blond-haired fair-skinned individuals often fare badly. They are the ones with delicate mucosa.

FIGURE 1

Schematic representation of the urethral canal and important structures opening into it

A. Infections of the urethra anterior to the Danger Zone are self limited, and if any structure opening into it becomes involved, the downward direction aids drainage. Should it become chronically inflamed the focus is readily accessible to instrumentation.

B. The structures posterior to the Danger Zone drain against gravity (as the epididymis, or vas deferens), or through narrow channels (as the ejaculatory duct and prostatic ductules), and if involved, the condition has a tendency to be prolonged indefinitely.

2 **Improper General Care.**—It is more important to impress upon patients to avoid fatigue from overwork and excessive use of the lower limbs than to prescribe a complicated diet difficult to carry out. Liquors should of course be banned, water should be taken freely, overeating should be avoided, but there seems to be no harm in meat or "red meat." It is rest which should be stressed. Dancers, chauffeurs, truckmen, bicycle riders, peddlers, etc., must be especially careful. The obviously important interdiction against eroticism, sexual intercourse, should be made routinely, for often sweethearts continue to "pet", husbands maintain the same sleeping quarters with their wives, salacious shows and suggestive movies are frequented.

3 **Improper Local Care.**—This accounts for the greatest number of complications. There seems to be an unbounded faith in the curative value of local injections. Physicians and patients alike consider them of paramount importance. When a patient does not do well, either the im-

stillations are increased in frequency or strength or other potent ones substituted. When a posterior urethritis develops, deep and forceful irrigations are often instituted; catheters are passed

FIGURE 2

Schematic representation of the structures which can become involved when the infection extends beyond the Danger Zone.

It is of interest to note that both the urethra and its appendages are lined by the same type of cell, columnar or transitional; an epithelium which is extremely vulnerable to invasion by the gonococcus. Above the trigone, the bladder is lined by stratified squamous cells, an epithelium which is mechanically resistant to the gonococcus, and thus this organ is practically immune.

into the posterior urethra in order to flush the region directly. Even sounds, Bang's instillators, and diathermy electrodes are inserted. Yet when one recognizes the salient fact that the gonococci are in the submucosa it becomes apparent that mild medications cannot reach them, and very strong ones, sufficient to penetrate and destroy the deep-seated organisms, must necessarily damage the overlying epithelium, interfere with the all-important process of phagocytosis, and thus leave an ideally fertile field for invasion by any cocci that remain. Not any of the chemicals employed today is a specific, not one can pick out the gonococcus, kill it, yet spare the surrounding cells.

Surface organisms and debris can be removed by gentle washings, and therefore, as cleansing agents irrigations are useful, but that is altogether different from the aim in their extensive use today. The passing of any instruments in the presence of a gonococcus-containing discharge (except in cases of retention unrelieved by other means) is absolutely contra-indicated.

The accompanying chart is a compilation of 25

cases, taken at random, in which complications had occurred. (Fig. 3.) In each, the possible causative factor was elicited and tabulated. The role played by improper local treatment is thus well illustrated.

Treatment of Complications:—When a complication occurs, its treatment supersedes that of the urethritis. The discharge, whether from the inhibitory effect of the rise in temperature or some other cause, is usually temporarily checked; whereas the complication fills the clinical picture and urgently demands relief. As already noted (Fig. 1), the structures along the urethra open into it through narrow tortuous tracts affording poor drainage and interfering with the effectiveness of injections or instrumentation. The use of the latter is dangerous. They may aggravate and extend the process. Bed, catharsis, fluids and sedatives are in order. A swollen testicle should be immobilized. Local applications of heat or cold, or some counter-irritant help to lessen the pain. An acutely swollen prostate may be gently palpated in order to establish the diagnosis, but must not be massaged. Hot rectal irrigations, and the insertion of suppositories of opium, codeine or atropine lessen discomfort. Similar measures should be resorted to in cases of seminal vesiculitis. Small doses of vaccine or foreign protein in gradually increased dosage, may be given with benefit. The acute process usually subsides within a week, and then it may go on as follows:

1. **Complete Resolution:**—Resolution similar to that in pneumonia can occur. The patient recovers completely from his complication, leaving the urethritis to be taken care of.

2. **Abscess Formation:**—The breaking down of foci is a frequent occurrence. The abscesses may rupture and drain spontaneously, when large and fluctuating, incision is necessary.

3. **Incomplete Resolution:**—Incomplete resolution and abscess formation often go together. Incomplete resolution constitutes the greatest group. It is the usual cause of failure to cure, of mistaken prognoses and of recurrence. The poor drainage characterizing these foci accounts for their chronicity. In them the gonococci may remain virile, in symbiosis, dormant, attenuated or displaced by secondary invaders. How long a gonococcus will remain alive in a given focus is a moot question. Some claim that within a year or two the organism will become extinct, and cite as an example the frequency of sterile cultures in cases of salpingitis. Others are of the opinion that gonococci never disappear, and call attention to the so-called "spontaneous" recurrences which come after an apparent cure of many years standing, of rheumatic states and iritis traced to long standing gonorrheal foci; and ask why the gonococcus could not persist in its pocket any less than the tubercle or typhoid bacillus. It seems logical to accept both points of view; for while there is

FIGURE 3
ANALYSIS OF POSSIBLE ETIOLOGIC FACTORS IN TWENTY FIVE CASES OF GONORRHEAL URETHRITIS WITH COMPLICATIONS

Case No	Name	Duration of Infection	Duration of Complication	Type of Complication	Possible Etiologic Factors as Elicited from Patient's History
1	P C.	2 wks	23 ds	Acute Prostatitis	Admitted coitus in presence of discharge. Was not warned by his doctor, and he thought that by means of a condom no ill effects could follow. Prostatitis developed 2 days after coitus.
2	J C.	2 wks	1 wk	Acute Epididymitis	Admitted coitus at height of infection, and treated himself immediately afterward with a very strong medicine which he himself prepared. Evidence of posterior involvement occurred next day.
3	J F W	4 wks	4 ds	Acute Epididymitis	Admits occupying same bed with wife while infection was at its height. Erotic effects followed. Not cautioned by his physician.
4	D Mc	8 wks	5 ds	Acute Epididymitis	Went on alcoholic spree two days prior to onset of complication. Not warned by his doctor.
5	D B	4 wks	5 ds	Acute Epididymitis	Three days before onset of epididymitis he went swimming and diving. Overdid it. Posterior involvement noted following day. Was not warned about danger of certain type of overactivity.
6	G H	2 mos	12 ds	Subacute Epididymitis	Two weeks ago his doctor changed the treatment, because the infection was persistent. He gave a deep injection with a strong medicine which burned strongly. That week the testicle swelled.
7	F W	5 wks	3 ds	Acute Epididymitis	Had intercourse 1 week ago. Was not warned.
8	F N	2 wks	1 wk	Acute Prostatitis (Acute Epididymitis later)	Sound passed by his doctor 9 days ago. Posterior involvement noted next day.
9	C E. B	5 wks	1 wk	Acute Epididymitis Acute Arthritis Vesiculitis	His physician passed a catheter daily and irrigated the urethra. Posterior Urethritis developed almost at the beginning of treatment.
10	A O	3 mos	2 mos	Abscesses of Urethra Abscess of Prostate Acute Epididymitis	Treated with catheter from the start. Entire urethral tract involved. In addition to this patient was allowed a young pretty nurse, and was in constant state of eroticism.
11	M K	17 ds	2 ds	Ac Ac	by Janet Irrigator Medicine bladder
12	M S	4 mos	1 wk	Acute Vasitis Acute Epididymitis	Had Diathermy treatments. Electrode passed into urethra twice weekly. Evidence of posterior involvement from the start.
13	J Ca	8 mos	6 mos	Recurrent Epididymitis Seminal Vesiculitis	Treated by Gravity Method. When a complication occurred medicine was changed (a stronger one than the preceding).
14	M H	8 ds	4 ds	Acute Prostatitis	Made up a solution of silver nitrate which he himself injected and noticed severe burning from the start. Meatus black from silver nitrate burn.
15	Ch J	4 wks	3 ds	Acute Prostatitis	His doctor passed a sound because 'he was not doing well'. Two days later evidence of posterior urethritis.
16	M K	10 wks	4 wks	Subacute Epididymitis	His doctor used Gravity Irrigator. Patient injected himself via piston syringe.
17	J K	2 mos	5 wks	Acute Epididymitis	Ate no meat, but drank alcohol.
18	J A.	3 mos	5 wks	Subacute Epididymitis	Treated via catheter. Used cotton as dressing. It acted as a plug and as a source of re-infection. Had tight foreskin. Refused circumcision.

Case No. Name	Duration of Infection	Duration of Complication	Type of Complication	Possible Etiologic Factors as Elicited from Patient's History
19. S. T.	2 mos.	2 wks.	Subacute Epididymitis	Apparently no obvious cause for the complication. Was a chauffeur and drove about all day. Allowed <i>bladder</i> to become <i>overdistended</i> if inconvenient to urinate.
20. M. S.	1 wk.	2 ds.	Posterior Urethritis Prostatic Abscess	Treated with diathermy.
21. J. R.	2 wks.	3 ds.	Posterior Urethritis Acute Epididymitis <i>later</i>	No obvious cause. A <i>blond haired</i> individual.
22. H. B.	5 mos.	3 mos.	Subacute Epididymitis	Used a <i>piston-syringe</i> . <i>Pin-point meatus</i> . Urethritis began to improve with meatotomy.
23. G. D.	6 wks.	1 wk.	Acute Prostatitis	Was treated with <i>Gravity Method</i> . Medicine changed several times because he was not doing well. Each time medicine was " <i>stronger</i> ."
24. P. B.	2 wks.	2 ds.	Acute Prostatitis	<i>Gravity Method</i> used. No advice against taking spices or alcohol.
25. E. A.	10 ds.	2 ds.	Acute Prostatitis	Received diathermy treatments. Electrode passed into urethra.

a tendency for the host to sterilize a gonorrheal focus, this tendency varies with each patient; with the location and character of the infected area, with the type of local treatment (or maltreatment); and with other unknown factors.

It is conceivable then, that any given focus in the urethral tract, if unmolested, can in time develop sufficient local resistance to the gonococcus and build a barrier against it. The organism will become dormant and finally die. However, it is also apparent that at any time before the last gonococcus dies, any favorable circumstance to the organism, such as an alcoholic debauch, or any form of local irritation, can break down the barrier or open up new channels. The interval between the development of the local barrier, and the extinction of the invader varies in each case. It is because of this, that confusion as to relapses, and cures has arisen. Therefore, in the treatment of a chronic focus, the criteria of cure must be applied with special care and patience.

DETERMINATION OF CURE

A. Uncomplicated Case:—Positive evidence of cure in a case of gonorrhea is not obtainable. All the evidence is indirect. One can merely tell the patient that, in view of the tests being favorable to him, the *probabilities* are that he is cured. The writer has taken the following steps before discharging any patient:

1. Prostatic Massage Test:—When the discharge has stopped, and the urine has remained clear for about a week, the patient is given a prostatic massage and the expression, if any, examined for pus and gonococci. If the test is negative, the massage is repeated in three to four days, and if again negative, the next step is taken.

2. Alcohol Test:—The patient is advised to take some alcohol, and is again observed for several days thereafter.

3. Coitus Test:—If the two preceding tests do not elicit any purulent reaction, or the appearance of gonococci, the patient is allowed to have intercourse (using a condom for protection), and then he is observed on several occasions thereafter.

4. A Complement-Fixation Test, and a Wassermann Test are then taken.

It has not been necessary to make use of an injection of a specific vaccine, or the instillation of a strong chemical into the urethra, or the passing of a sound. The tests described above have proven sufficiently reliable.

B. Cases with Complications:—In addition to the procedures already mentioned, the injection of vaccines and the insertion of sounds are valuable aids. The various tests are applied with caution, and over a greater period of time.

CONCLUSIONS

It is important to keep the following facts and principles in mind when treating a case of gonorrheal urethritis in the male:

1. There is no cure at present for gonorrhea, but acute anterior gonorrheal urethritis has a tendency to be self-limited.

2. None of the preparations used today is a specific against the gonococcus.

3. The gentle instillations by the physician (as a surface washing), of small amounts of a warm and mild antiseptic solution, through a smooth-tipped glass syringe with a rubber bulb, is of value in keeping the patient comfortable, and the infected area clean.

4. The development of complications prolongs a case of gonorrhea indefinitely. Complications occur most frequently in cases with posterior urethritis.

5. Posterior urethritis and complications can best be avoided by proper general management,

and avoidance of excessive and irritating local treatment.

6. Complications are most apt to occur if forceful, frequent injections with irritating medications are made. The organisms are thereby enabled to get past the Danger Line. (Fig. 1.) The use of gravity apparatus is unnecessary. The insertion into the urethra of foreign bodies is contra-indicated.

7. Heroic chemical measures to eradicate a morning drop which is free of gonococcus or shreds in a clear urine (*i.e.*, immediately at the end of an attack of acute gonorrheal urethritis)

are unnecessary. They often lead to an intractable chemical irritation and secondary infection.

8. Gonorrhea with complications also has a tendency to get well if treated gently. But owing to the poor drainage of the involved area, its vulnerability to secondary invaders, and inaccessibility to direct treatment, chronicity in most instances is inevitable.

9. The evidence of a cure of a case of acute gonorrheal urethritis is indirect and negative in character. It should be obtained in every case and the patient should be given to understand both the purpose and significance of the tests.

TWO CASES OF THROMBOSIS OF BOTH CORONARY ARTERIES

By JAMES R. LISA, M.D., and ALFRED RING, M.D., NEW YORK, N. Y.

From Department of Pathology, City Hospital, W. I., Department of Hospitals, New York, N. Y.

IN a previous communication (1) a case of occlusion of both coronary arteries due to thrombosis was reported. The following two additional cases of bilateral coronary thrombosis were noted while analyzing one hundred cases showing cardiac infarction or gross myocardial fibrosis in another study.

Case 1. J. T., age 60—colored. Admitted January 2, 1930 and died twenty hours after admission.

The patient entered the hospital in a state of shock, T. 94.6°, P. 58 and very weak, R. 14 and shallow. B.P. unobtainable, skin cold and clammy. No history could be elicited. Examination revealed equal, somewhat contracted pupils, the right fixed and the left sluggish to light; emphysematous chest with hyperresonance; heart sounds faint with no murmurs; abdomen negative, absent knee jerks and abdominals but no pathological reflexes or evidence of paralysis. Urinary examination showed a trace of albumin, granular casts, a few R.B.C. and many W.B.C. Blood Urea Nitrogen 42 mgm. Blood Wassermann —negative.

The patient showed no response to attempted stimulation. Temperature rose to 103° and pulse to 120. Semi-comatose state persisted along with marked restlessness. Exitus occurred within twenty hours after admission. Diagnosis was cerebral hemorrhage and syphilis of the central nervous system.

Anatomical Diagnoses: Old and recent cardiac infarction, coronary thromboses, syphilis of aorta, arteriosclerosis of brain and kidneys, cirrhosis of liver, chronic suppurative prostatitis and lymphosarcoma of mediastinal and upper abdominal nodes.

Heart: Weight 300 grams. Pericardial sac contained a normal amount of clear fluid. The parietal pericardium on the posterior surface of both right and left ventricles was adherent. All chambers were dilated and filled with currant jelly clot. The valves were all normal. At the apex of the left ventricle was a fresh, moderately adherent clot around the periphery of which were smaller adherent thrombi. The endocardium of the upper portion of the left ventricle extending on to the interventricular wall was depressed, thick, white and scarred. Section of the left ventricular wall revealed a large, white scar occupying about two-thirds of the wall. This scar extended into the upper posterior portion of the interventricular wall. The remainder of the left ventricular wall was very soft and spotted thruout by numerous small hemorrhagic and yellow areas. The entire musculature was very soft and light yellow brown in color. The aorta in its first portion had a crescentic area, thick, raised, firm, yellow white in color, sharply delimited and distinctly pig skin in appearance. The remainder of the aorta showed moderate atheromatous changes. The left coronary commissure was moderately widened.

Coronary Vessels: The mouth of the left coronary was wide. The vessel wall of the main branch was thickened with patchy sclerosis but had a wide lumen. Microscopy of this portion of the vessel revealed intense atheromatous and slight calcific deposits in the wall. At the periphery of the cholesterol deposit there was a lymphocytic and phagocytic cell reaction. The elastica was disorganized and the adventitia showed only a slight lymphocytic reaction.

FIGURE 1

Case 1. Section through the circumflex portion of the left coronary artery at the uppermost portion of the fresh thrombus showing the intense atherosclerosis and narrow extrinsic lumen.

The first two centimeters of the anterior descending branch had a thicker, more calcified wall, and contained a thrombus one centimeter in length, which was organized and canalized. Below this point the vessel wall was thickened with moderate narrowing of the lumen but no thrombosis. Small accessory branches contained recent thrombi.

FIGURE 2

Case 1. The circumflex portion of the right coronary artery with the completely organized thrombus and very fine canalization (A).

The circumflex branch of the left coronary artery was also thrombosed, the thrombus beginning just beyond its most proximal portion. Microscopy revealed this to be a recent thrombus within a markedly thickened and arteriosclerotic wall with heavy calcific deposits and active organization. The adventitia showed heavy perivascular lymphocytic foci. The small neighborhood arteries had markedly hyperplastic media. Beyond the thrombus the vessel wall was less sclerotic with a wide lumen and showed no evidence of inflammatory lesions.

The mouth of the right coronary was slightly irregular and slightly narrowed by fibrosis. The proximal third of the main trunk had marked arteriosclerotic changes and a wide lumen. The middle third was intensely arteriosclerotic and apparently completely thrombosed. This thrombus was old and well organized. Microscopy showed some canalization. The right circumflex branch had a good lumen but a thick, stiff wall. In the most proximal portion of the posterior descending branch was an organized thrombus, one-half centimeter in length in a pipe-stem portion of the vessel. Below the thrombus the wall was thickened and fibrosed with a narrow eccentric lumen. Beyond this the vessel wall appeared grossly normal.

Case 2. C.H., age 65 — white. Admitted August 16, 1930, with diagnosis of cardiac decompensation.

His chief complaint was marked dyspnea. His illness dated back twelve years with periodical "heart attacks." These became more severe and frequent as time went on. He also noted swelling of his ankles and nocturia.

Examination revealed a well developed and nourished elderly male evidently markedly dyspneic. Pupils reacted to light and accommodation. Lungs were emphysematous with rales at the bases. Heart was enlarged, apex beat being in the 6th intercostal space outside the nipple line. Sounds were distant. B.P. 108/78. Abdomen was thought to contain some fluid; liver was enlarged to three fingers below the costal margin. Both legs were edematous. No knee jerks could be obtained. Tentative diagnosis was chronic myocarditis with insufficiency and chronic nephritis. Urinary examination: Specific gravity 1.012, albumin two plus, glucose negative, few fine and coarse granular casts.

The evening of admission the patient was obviously in serious condition. Despite medication with morphine, he remained quite restless with progressively increasing dyspnea. The following day he was quite cyanotic with cold extremities. His pulse became imperceptible and he died about thirty-six hours

after admission. His temperature had hovered between 101° and 103°, pulse between 70 and 90, and respirations between 20 and 32.

Anatomical Diagnoses: Old cardiac infarction, coronary sclerosis with thrombosis, chronic myocarditis, general arteriosclerosis, chronic passive congestion of all organs, chronic gastritis.

Heart: Weight 650 grams. Appeared quite enlarged. Many small areas of hemorrhage were noted both on visceral and parietal pericardium. Tricuspid and pulmonic valves were normal. The mitral and aortic valves showed some atheromata at their bases but were otherwise negative. The left ventricular wall from the apex up about seven centimeters showed a marked thinning. At the apex the wall was slightly thicker due to the gelatinous

FIGURE 3

Case 2. The circumflex portion of the left coronary artery proximal to the point of most marked narrowing.

remains of heart muscle. The endocardial surface of the entire area was covered by several layers of organized and adherent thrombus. At the upper end of the area, the thinning was so marked that endocardium and epicardium seemed apposed. The aorta showed marked arteriosclerosis, some ulcer formation and a small area of striation in one portion of the arch.

Coronary Vessels: The mouth of the left coronary was wide with speckled atheromatous deposits. Beyond the mouth in the main branch the same changes were present. At about the mid-point of the left circumflex artery there was a transition from a comparatively soft wall to one with intense arteriosclerosis and complete thrombosis with organ-

FIGURE 4

Case 2. The right coronary artery showing the extremely narrow excentric lumen and the marked arteriosclerosis.

ization. This thrombus occupied the artery for a distance of about one centimeter. Beyond this was a softer wall with an early propagated thrombus. The remainder of this branch was comparatively normal. Just beyond the proximal portion of the anterior descending artery was a thrombus completely occluding the vessel. The wall here was pipe-stem in character. Below the thrombus the lumen was small, almost pin-point and ex-

FIGURE 5

Case 2. The anterior descending branch with the organized canalized thrombus.

centric. This was followed by another stretch likewise completely occluded. In about the mid-portion of the interventricular septum the lumen was very narrow but not thrombosed. At about the junction of the middle and lower one-third of the wall there was complete thrombosis again. Beyond this the vessel could not be traced grossly.

The mouth of the right coronary was only slightly narrowed with a funnel-like type of deformity. The proximal portion of the artery was thick-walled with a large lumen but not thrombosed. About one centimeter beyond the mouth was a pipe-stem area completely thrombosed by old, organized thrombus. This extended thruout the major portion of the main and circumflex branches and passed gradually into a portion with an extremely fine and excentric lumen. This change did

not extend into the posterior descending branch to any degree. However, the proximal portion of this vessel had a thick wall with a slightly excentric lumen. The lower three-fourths of the posterior descending branch was grossly normal.

SUMMARY

Two cases are reported showing bilateral coronary thromboses. In one case the thrombi were old and the myocardium showed old cardiac infarction. In the other case in addition to these findings a fresh thrombus with recent infarction was noted.

Thanks are due to Miss L. B. Miller for the microphotographs.

REDUCING DIETS

By ARTHUR H. TERRY, JR., M.D., NEW YORK, N. Y.

In a previous article in the *NEW YORK STATE JOURNAL OF MEDICINE*, October 1, 1929, page 1192, the reducing diet was discussed with special reference to its effect on blood pressure in the obese. This present article aims to present concrete diets for the many people whose principal complaint is obesity, and who come to the doctor's office for the purpose of getting thin.

Patients expect the doctor's directions regarding their diet shall be as explicit as those regarding their doses of medicine—what to eat, how much, and when. They will eat a specified diet prescribed by their physician much more willingly than one which they estimate for themselves after much effort and confusion of thought. However, after patients have seen the effect of the diet prescribed by the doctor, they will use their intelligence and experience in devising changes, to suit their individual tastes.

Two types of diet are here presented, together with lists of vegetables arranged according to carbohydrate content. The amount of food is measured in grams, in order to conform to the

amount of carbohydrate, protein, and fat contained, so that the total calories may be seen and calculated by those to whom arithmetic is no burden. Household measures are also provided for those preferring neither to toil nor to spin.

The strict diet is very low in calories, but ample in choice of protein from the meat, fish, and fowl groups. This pattern may be further reducing without injury by elimination of the 10% vegetables. It may also be rendered less severe by adding a 20% vegetable, or a slice of bread at each meal, thereby increasing the carbohydrate content about 60 grams, and consequently the total calories by about 240 grams.

The Seven-Day Diet is less exacting physically or mentally, providing an average of 900 calories daily with 55 grams of protein. Vegetables and fruits may be varied to suit the taste by substituting others of the same carbohydrate content. No fats are to be used in cooking.

Either of these regimes has ample protein, yet such an insufficiency of total calories that the fat melts away like a lighted candle.

CARBOHYDRATE CONTENT OF FRUITS AND VEGETABLES

	5%	10%	15%	20%
Asparagus	Brussel sprouts	Beets	Green peas	Beans—Lima
Celery	Broccoli	Carrots	Parsnips	Beans—Baked
Cucumber	Cauliflower	Pumpkin	Apples	Beans—Shell
Chard	Cabbage	Squash	Cherries	Green corn
Endive	Egg plant	Turnip	Grapes	Macaroni
Greens	Artichokes	Blackberries	Huckleberries	Potato
Lettuce	Leeks	Muskmelon	Pears	Rice
Marrow	Mushrooms	Oranges	Raspberries	Banana
Rhubarb	String beans	Peaches		Figs
Spinach	Sea kale	Pineapple		Plums
Sorrel	Tomato	Strawberries		Prunes
Sauerkraut	Grapefruit	Watermelon		

Explanations

1 gram (G) of carbohydrate (C) = 4 calories	A H = average helping
1 gram of protein (P) = 4 calories	h tb = heaping tablespoon
1 gram of fat (F) = 9 calories	30 grams = 1 ounce = 2 tablespoonfuls
1 gram of alcohol = 7 calories	8 ounces = 1 glass
House measurement (H) = tablespoonfuls	6 ounces = 1 coffee cup

THE SEVEN-DAY DIET

First Day	BREAKFAST	G.	H	C.	P.	F.

A STUDY OF THE DEEP AND SUPERFICIAL REFLEXES OF THE NEW-BORN

By JOHN H. NOLAN, M.D., NEW YORK, N. Y.

THIS study was undertaken because of the many conflicting reports on reflexes in infants. Garrod, Batten, Thursfield and Patterson,¹ without indicating that their examinations were done on new-born, state that the "abdominal reflexes are not present in young babies." They add that the "cremasterics are also developed during the first year of life. Knee jerks are present. Ankle jerks may be absent if knee jerks are absent." Their view of the plantar reflexes is as follows: "In babies the toe is sometimes flexed, but more often the big toe is sharply extended and, in association with this, the little toes are extended. It is the slow extension of the big toe which is of important diagnostic value."

Dunn² says that the knee jerks are hard to elicit, and should be disregarded if absent unless there are some additional signs of disease of the nervous system.

Crothers³ states that the superficial reflexes are extremely erratic in childhood, and that the Babinski phenomenon, if constantly present on one side alone, is significant. Rolando⁴ gives it as his opinion that, because of the variety in type and intensity of reflexes in the new-born, no standardization is possible.

Von Reuss⁵ comes to the conclusion that: "Opinions concerning the condition of the various reflexes in the new-born are by no means in agreement. This fact is doubtless due in part to the fact that some reflexes, even when they are quite active, cannot always be elicited, owing to the low tone of the muscles of the extremities. The knee jerk can almost always be elicited as early as the very first day, and is usually fairly active. During the first weeks, Furmann was frequently able to obtain reflexes on both sides of various strengths. According to Furmann, the ankle jerk is positive in sixty per cent of cases. Bychowski was only able to elicit it four times out of sixty-four children under six months old. Babinski's plantar reflex is, according to Furmann, positive in the majority of cases. Stroking the inner border of the sole always produces dorsiflexion of the big toe under normal conditions (Engstler). The reflexes are often very brisk. According to Furmann, the cremaster reflex is positive in the majority of cases in the first six weeks; Cattaneo was not able to observe it during the first three months; Peritz thinks it is seldom present; Farrago, on the other hand, only failed to obtain it in 10% of cases. Furmann considers that the abdominal reflex is but seldom observed in the first period of life; Bychowski also does not count it among the congenital reflexes. Farrago, on the other hand, was always successful in eliciting it in 117 children, by stroking the region above the mons veneris

with a needle. The pharyngeal and nasal reflexes are usually but not always observed, premature infants especially often show a very slight reaction in this respect."

There seems to be a prevailing belief that the presence or absence of reflexes may be normal and that a Babinski sign appearing up to the age of two years may be regarded as normal. Moreover, no effort has thus far been made to indicate the relative degree of activity of the reflexes. In the present study, observations were made upon the reflexes of thirty-three new-born babies in the service of Dr. L. S. Loizeaux at the Fifth Avenue Hospital, New York City, ranging in age from a few moments to fourteen days. Six additional breech presentations were examined before birth. In specifying the degree of reflex activity, the symbols used in the neurological department of the Vanderbilt Clinic were employed, *i.e.*, 0, absent; 1, weak response; 2, active; 3, very active; 4, with transient clonus; 5, with permanent clonus.

In order to insure more satisfactory conditions a routine procedure was closely followed.

The Method: Usually the baby was picked up asleep on its pillow. It was not undressed, excepting insofar as was necessary for proper exposure. At first the diaper was loosened and laid open and then the abdominal binder was opened to give a proper field. The reflexes were then tested in the following order:

(1) Abdominal Reflex. These were the most difficult to elicit and were always tested before the baby had a chance to wake up or cry. If he could be examined while asleep or when quiet, the sharp point of an open safety pin was lightly stroked in the usual manner over the lower and upper abdominal quadrants. At first a very light touch was tried and, if successful, the results recorded. If not successful varying degrees of pressure were brought to bear. Of the thirty-three babies examined, thirty-two gave a prompt reaction in all quadrants the first day tested; the thirty-third baby responded the second day. The failure on the first examination may have been due to overdistension of the abdomen with gas. I also found that babies with considerable wrinkling of the skin due to loss of weight or whose abdomens were wet or covered with vernix caseosa did not respond readily.

(2) Cremasteric Reflexes. The testicles being in the scrotum and the scrotum being relaxed, light stroking of the inner and upper side of the thigh elicited this reflex promptly in each of the eight boys in the series. Even pricking the sensory area in almost any spot in the distribution of the genito-crural nerve gave positive results.

(3) Plantar Reflexes. A safety pin point was

used in making this test. Because of the exquisite hyperaesthesia of the outer portions of the soles of the feet in all babies, considerable time had to be spent in an effort to offset the resulting defensive withdrawal of the foot. The sole was touched lightly here and there with the point of a safety-pin. The baby at first would violently jerk his foot away, but after a little while he would become accustomed to the stimuli. Then the test was made as lightly as the pin could be drawn along the outer edge of the sole from heel to toe. In all the children during repeated tests, both plantar and dorsal flexion could be obtained, but twenty-seven showed more plantar than dorsal flexion responses and six showed about equal reactions. In no case was a constant Babinski present.

It is my conviction that the dorsal extension of the great toe usually observed (alternating with plantar flexion) is part of a normal defense reaction but that a Babinski reflex, if constantly present without such alternation, cannot be considered normal.

The plantar reflex was tried in at least six breech presentations before the baby was born and plantar flexion was obtained in all more frequently than dorsal flexion.

The plantar reflex is one of the earliest if not the first of the reflexes to appear in the new born. In two cases of asphyxiation I was able to obtain the plantar reflex at least several minutes before I could elicit the corneal, pupillary or pharyngeal reflexes during the process of resuscitation. The plantar reflex is obtainable in breech presentations before delivery even when the mother is deeply anaesthetized.

(4) Patellar Reflexes. It was found that even a small reflex hammer was too large to tap the quadriceps tendon exactly in the right spot. The method used was to employ a heavy teaspoon as a percussion hammer. The leg was flexed on the thigh, the tendon was localized with the thumb and was tapped briskly by the edge of the bowl of the teaspoon. Twelve babies gave a very active (3) response, sixteen gave active (2) responses, and five gave weak (1) responses. If the response was not forthcoming at once, many attempts were made, placing the leg at different angles. In every event all babies reacted during the first trial.

In six breech extractions, the patellar reflex could not be obtained during the process of birth.

(5) Achilles. The baby was now turned over on his abdomen, the foot was gently grasped and dorsiflexed to stretch the Achilles tendon and take up the slackness of the calf muscles. The tendon was struck in the same manner with the

edge of the teaspoon. Fourteen cases were (1) plus, seventeen (2) plus, and two gave no reaction on the first day. These two reacted promptly the next day. My experience has shown that these tests cannot be performed satisfactorily unless the babies are relaxed and quiet.

In the six breech cases, the normal Achilles reflex was obtained before birth, in every case, if the mothers were lightly anaesthetized. Under deep anaesthesia, the reflex was not elicited.

(6) Biceps. The upper clothing was now gently removed, the arm was flexed to a right angle, and the biceps tendon was isolated by finger and tapped smartly with a small reflex hammer. Twenty gave (1) plus, thirteen a (2) plus reaction.

(7) Triceps. The arm was flexed to bring out the tendon which was tapped with the edge of a spoon. Twenty eight gave a (1) plus reaction and five a (2) plus.

Various other reflexes were tested, such as the jaw jerks which were always active. The pectorals were usually (1) plus. The pharyngeals were always present and active in normal cases.

(8) Corneal Reflexes. These were tested by applying a small point of paper or a wisp of cotton to the cornea. It was necessary to give a definite amount of touch. The reflex response was prompt in every case.

(9) Pupillary Reflexes. The baby's head was turned away from the light, the eyelids were gently opened by the nurse and light was introduced from the side. The size of the pupils naturally depended upon the degree of darkness of the room. In twenty seven cases they were 2 mm., in six they were 3 mm in diameter. The reaction in the thirty-three cases was present but not brisk.

The results show that in following the technic described in a series of thirty-three quiet babies, the deep and superficial reflexes are present in new born normal infants and that a plantar response was more frequently obtained than a defense Babinski reflex.

VENEREAL DISEASE CONTROL

The civic aspects of the treatment and prevention of venereal disease were considered by the Committee on Public Relations of the Medical Society of the State of New York as reported on page 979 of this Journal. The history of the anti-tuberculosis movement is repeating itself in venereal disease control. Most general practitioners in past years have

not welcomed venereal patients for several reasons:

1. Social stigma.
2. Unreliability of the patients.
3. Lack of accepted standards for diagnosis and treatment.
4. Unwillingness of doctors to provide the

diagnostic and therapeutic equipment without the prospect of an adequate financial return for their outlay.

Departments of Health and genitourinary specialists have developed standard methods of diagnosing and treating venereal diseases.

Public Health organizations and laymen have popularized the education of the people regarding venereal diseases and the methods of their control, and have aroused public sentiment to demand the establishment of facilities

for the diagnosis and treatment of this class of affections.

Medical societies are giving more and more consideration to the opportunities and duties of practitioners of medicine in venereal disease control.

The Committee on Public Relations is in close contact with the New York State Department of Health and the State Charities Aid Association, and is developing a working plan for the satisfactory cooperation of the three groups in venereal disease control.

A HOSPITAL MEDICAL LIBRARY

An article on a Hospital Medical Library by Charles Frankenberger, Librarian of the Medical Society of the County of Kings, New York, was printed in the June Bulletin of the American College of Surgeons. The author outlines a plan adapted to the larger hospitals which can afford to purchase the books and to employ a librarian to look after them. (See page 983)

The Associated Physicians of Long Island is developing a plan by which the resources of a large central library may be made available to medical societies and smaller hospitals in the surrounding territory. The Library of the Kings County Medical Society ranks among the largest medical libraries in the United States; and its governing board offers its services to medical

groups throughout all Long Island. The plan was first suggested over twenty years ago, but was not developed because of the lack of organized groups of physicians in the several geographic centers of Long Island. But the organization of hospital staffs and of group medical societies subsidiary to the county societies, have provided the means by which the books may be distributed and returned. The clerk of a hospital, for example, may attend to the routine of ordering the books, keeping a record of their distribution to the doctors, and attending to the details of their return to the Brooklyn library. It is probable that the service will be inaugurated in the Fall, and demonstrate how a library may serve the physicians of several surrounding counties.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

The Alcohol Problem: That there is very little new in the alcohol problem is shown by the following items in this Journal of August, 1907:

"Provision for Drunkards.—The annual report for 1906 of Bellevue and Allied Hospitals shows that the State abounds in charitable enterprises for almost every class of unfortunates, but as yet provides no institution for those who have become the slaves of alcohol. Such institutions if they could be established, might convert a certain proportion into useful citizens again. It is suggested that habitual drunkards should be committed by proper judicial authority to State

or municipal institutions in which they might be restrained and treated scientifically. The cost of maintaining such institutions would be considerable, but their need will not be questioned.

"To check the prescribing of liquor:—The Jefferson County Medical Society, in Alabama, has placed itself on record as being opposed to the indiscriminate prescribing of liquor by physicians, and suggests, to limit such illicit prescriptions, that every prescription be recorded in a book open to inspection by the county health officer, the record to show the name of the prescriber, date, amount and kind of liquor."

MEDICAL PROGRESS

The Inoperable Prostate.—Kenneth Walker, writing in *The Practitioner* for June, 1932, while claiming that prostatectomy is the ideal treatment in the majority of cases of prostatic obstruction, admits that there are a certain number of patients who for one reason or another cannot or will not consent to this operation. The author therefore notes the different methods of treatment other than exsection which may give relief to the prostatic sufferer. These he considers under the headings of (1) medical treatment, (2) electrotherapy, (3) minor surgery. It is not possible, he says, to reduce the size of the gland by medical treatment, yet symptomatic relief may sometimes be so obtained. Retention may be due to the size of the prostate or to spasm of the sphincter, the latter being often that which calls most urgently for relief. The symptoms in such a case may vary greatly, the patient at one time being able to pass water with the greatest ease and being disturbed only once or twice in the night. This condition calls for the avoidance of any kind of exposure, especially to cold and damp. Warm clothing is most important and overfatigue of mind or body is to be most scrupulously avoided. There is little to be said concerning the diet other than to caution against alcohol, strong coffee, and highly spiced viands, which are absolutely forbidden. Alkaline drinks are to be recommended and the bowels must be kept open, though without purgation; warm enemas may be useful.

The most usual forms of electrotherapy are diathermy, the static wave current, galvanism, and the x -rays. Diathermy probably acts by diminishing spasm of the sphincter vesicae. The x -ray may be used alone or in conjunction with the static wave or diathermy. In order to effect a reduction in the size of the prostate enormous doses must be given, thereby incurring the risk of injury to the skin or to the mucous membrane of the rectum. Electricity in the form of the sinusoidal current, the static wave, galvanism, or the high frequency current acts by causing either contraction or relaxation of the muscle fibers. The effect of contraction of the sphincter brought about by massage or by electrical means is to dispose of the prostatic secretion and epithelial cells which fill the acini of the enlarged gland.

When the amount of the residual urine increases and renal efficiency is thereby threatened, partial emptying of the bladder is im-

perative, and for this it may be necessary to resort to catheterization which, however, reduces markedly the life expectation of the patient. Better is it to establish permanent suprapubic drainage with all its inconveniences. But if the main obstruction comes from the presence of an enlarged middle lobe or a fibrous bar, "forage" is indicated and will enable micturition to be reestablished. The operation may be done satisfactorily under low spinal anesthesia.

The Physiopathology of Senility and the Neurochemism of the Aged.—A study of the problem of senility shows, says Nicola Pende, that in the entire complex of senile changes it is the mesenchymal apparatus that is failing. To this belong not only the so-called histiocyte and reticulo-endothelial system, but also the elastic tissue, the adipose tissue, the adrenal cortex and the interstitial and lutein tissue of the genital glands. The mesenchyma is the *nutritive sponge* which bathes all the parenchymal tissues, sustains them with its elastic fibers, protects them from exogenous and endogenous poisons and repairs their losses. We know today that the earliest senile changes are not chargeable to the so-called noble differentiated parenchymal cells but to the mesenchyma. The atrophy of the elastic tissue of the skin, together with the capacity for fixation of water and salts on the part of the colloid micellæ, with passive accumulation of water in the connective tissue, is what causes the first wrinkles and the first collections of fat in face, chin, and abdomen, where the skin most readily yields to the action of gravitation; and it is the atrophy of the connective tissue that produces the first senile changes in the lung and in the intima of the arteries. Similarly the atrophy of the lymphatics and connective adipose tissue substitutes hard fibrous connective tissue for the nobler elements of the mesenchyma. In short, there is in the aged an involution, a decadence of the great mesenchymal apparatus, between the ages of 50 and 75. We know that the mesenchyma, together with certain endocrine glands of mesodermal origin which probably stimulate the reticulo-endothelial function, is the regulator of lipid metabolism and of acid-base equilibrium. A senile insufficiency of this entire apparatus must lead to deficient fixation of lipoids in the tissues, with all its secondary results in loss of nervous and muscular energy. We may therefore conceive that in the last analysis the essential morphologic-dynamic change is the functional degenerescence of the mesenchyma, that is, of the group of tissues whose function is to protect the

parenchymal tissues from physiologic intoxication by their own catabolized acids, and to furnish them with their indispensable lipoids in a form readily utilizable. It is not the noble elements of the parenchyma that degenerate, but the humoral medium in which they are bathed. Prolongation of the period of vitality of such organs as brain, heart, liver, kidneys, and endocrine glands can be accomplished only by caring for the integrity of the humble working class of cells represented by the mesenchymal vegetative apparatus.—*Riforma medica*, October 12, 1931.

Endometriosis and Endometriomata.—Daniel Dougal discusses the principal etiological, pathological, and clinical features of endometriosis and endometriomata on the basis of 137 cases in which he has operated during the past five years. He defines endometriosis as the pathological state brought about when endometrial fragments invade the uterine wall or, passing through the Fallopian tubes in regurgitant menstrual blood, reach the pelvic cavity and structures within it. When these endometrial implants proliferate sufficiently to form tumors they are known as endometriomata. Cullen's diverticula and Sampson's retrograde menstruation and cellular spill are accepted as providing the most reasonable explanation of uterine and extrauterine endometriosis, respectively. The tumors are largely made up of hyperplastic fibromuscular tissue, containing numerous islets of misplaced endometrium, some of which become cystic and filled with blood. Stress is laid on the multiple character of these lesions. Tumors are not infrequently found on the Fallopian tube, round or uterosacral ligaments, pelvic colon, small intestine, and more rarely in the appendix, umbilicus, inguinal canal, or scar of a previous abdominal operation. In Dougal's series the tumors were distributed as follows: Diffuse uterine, 6; cornual, 6; ovarian, 44; rectovaginal, 44; ovarian and rectovaginal 34. There appears to be no relationship between endometrioma and carcinoma of the uterus. There are no pathognomonic symptoms of endometrioma, but increasing dysmenorrhea, menorrhagia, and dyspareunia should lead one to suspect the condition. In the case of intrauterine growths, any fixation of the uterus and ovaries associated with a shotty nodular tumor behind the cervix affords conclusive evidence. While endometrioma, in the early stages is not an absolute bar to pregnancy, it seriously interferes with childbearing. Owing to its wide distribution and infiltrating character conservative measures are possible only in the early stages. In the author's series the uterus and all ovarian tissue were removed in 83 per cent of the cases. Total is preferable to subtotal hysterectomy; it is quite unnecessary to excise infiltrating growths in the rectum or other parts of the alimentary

tract, as atrophy will follow if both ovaries are removed.—*British Medical Journal*, November 21, 1931, ii, 3698.

Silent Pneumonia in Children.—G. Mouriquand and J. Savoie, writing in the *Journal de médecine de Lyon*, say that there is a form of silent pneumonia appearing in children, and especially in infants, which is not betrayed by any of the classic signs, such as râles, souffles or dullness. Its diagnosis is accordingly difficult, unless, with the possibility of pneumonia in mind, the physician has recourse to radioscapy, which will reveal the characteristic triangular shadow. The onset is sudden, the child runs a high temperature, usually without remissions; a dry cough may or may not be present, with expectoration. Respiration is superficial, and slightly labored. Nervous or meningeal phenomena may easily mislead in the diagnosis of this condition, of which persistent fever remains the essential symptom. Unexplained fever continuing for several days should lead the physician to look very carefully for 3 signs: (1) Limited sub-dullness that cannot be called true dullness; (2) respiratory obscurity, or, to a less degree, diminution of murmur; (3) exaggerated resonance of the cry. The sub-dullness, although not constant, is a good sign of the affection, and may be the only one. It must not be looked for in any considerable zone of the thorax, but should be sought not only in the back, but also in front, under the clavicle and in the axilla. The area of dullness may extend, so to say, only the breadth of a fingertip. It is not at all unusual to find the focus at an antero-axillary spot, or deep within the axilla. Respiratory obscurity is not so constant, but deserves to be looked for, as it is an early sign; it is ordinarily quite localized, and may be masked by a compensatory emphysema around the hepatized focus. The type of cry constitutes the best sign of all. A comparison of the sound when one listens alternately to the healthy lung and the hepatized focus shows in the former case a cry that sounds distant and badly transmitted, as if interrupted by a tissue that in some way deadens it, while in the latter case it seems close by, and piercing, produced immediately under the wall. This sign has been an invaluable means of diagnosis in a good many cases. In children too old to cry the same information is given if the child is asked to say *EE*. The sound undergoes a transformation in the pneumonic focus, and becomes *EH* (English long A) or even *AH* in transmission. A possible explanation of silent pneumonia is that it is not the triangle of hepatization that gives râles and souffles in any pneumonia, but the surrounding splenization and congestion. This congestion might conceivably be lacking, for some reason that at present eludes the most painstaking study.

The Shape of the Pelvic Brim as the Determining Factor in Childbirth. — Kathleen Vaughan points to the fact that in India the women who live out of doors, tending cattle, planting crops, doing heavy work, have their children safely and with no more difficulty than the animals around them have in parturition. Women of the same race who on account of the custom of "purdah" remain in seclusion find their confinements increasingly difficult. That difficult labor is not a racial question is further illustrated by the Negress. In her natural surroundings she gives birth to her children with ease, but when living in large cities in America she has more difficulty than the white woman herself. The fundamental cause of difficult labor and high maternal mortality is that the child's head and the mother's pelvis do not fit. The writer examined and measured the pelves of various races in the museum of the Royal College of Surgeons, and at once noticed that the female pelvis assumed a great variety of shapes—kidney-shaped, oval, round Y-shaped, and irregular, or one side larger than the other. The part of the fetal head which engages the pelvic brim is always a circle. This is the part known as the occipito-bregmatic circumference, which in full flexion is brought into the maternal brim; it is in this plane alone that the fetal head can be safely diminished in volume, while still preserving its circular form. Unequal pressure or pressure in other planes leads to tearing of the tentorium and hemorrhage. In England and America rickets is almost universal, and affects the bones most where growth is most rapid and calcification is proceeding most quickly. Such a part of the body is the pelvis. Pelvic development is influenced by the sacroiliac joints, and we know that ankylosis of these joints produces atrophy of the pelvis. The pelves at the Royal College of Surgeons showed that in native races the sacroiliac joints were well developed. All circular pelves have this joint well developed. Most important in the development of this joint is the crouching posture used by women living out of doors in attending the calls of nature. In England the still soft pelvis is bent by long sitting in school, and this is not counteracted by the proper action of the sacroiliac joints, which should be used daily, if only during the acts of defecation and urination. The wearing of high heels also limits and cramps movements, throwing the body weight forward on the arch of the foot, altering the pelvic angle and causing the back to be unduly hollowed to preserve the balance. It is of interest that perfect teeth are found with the round pelvis, and this is well understood among primitive people, who consider such teeth essential in a bride. These facts are the real explanation of our increasingly difficult maternity.—*British Medical Journal*, November 21, 1931, ii, 3698.

The Frequency of Syphilis of the Aorta.—On the basis of 1,000 autopsies performed on cadavers of adults in a large public hospital of the Middle West (U. S. A.) with 3,300 beds, whose patients are drawn from the poorest classes, R. H. Jaffé reports that he found syphilitic changes of the aorta in 10.3 per cent. The examinations covered the entire aorta, descending as well as ascending, which may account for differences in his figures from earlier statistics, which customarily relate only to the ascending aorta, although frequently the descending aorta alone is affected. These changes were 3 times as frequent in colored as in white patients (22.02 against 7.43 per cent). In females the discrepancy was much less marked (Negroes 10.14, whites 8.53 per cent). Despite the relative frequency of syphilis of the aorta in women, the mortality among these is small in comparison with men, being in white women 1.8 against 4.67 per cent in white men, and in colored women only 0.7 against 10.1 in colored men. The total mortality was 4.9 per cent. The importance of syphilis of the aorta is seen by a comparison of the figures with those for cardiac affections of rheumatic origin. Rheumatic valvular affections, acute and chronic together, were the cause of death in 2 per cent, while they were noted as secondary findings in 5.6 per cent. There was no essential difference between white persons and colored. The average age of death from lues of the aorta was 9 years younger in Negroes than in white persons, which is attributed to the early infection of the former. The overwhelming majority of the cases of syphilis of the aorta had received no specific treatment. Of the cases that terminated fatally, 76.5 per cent gave a positive precipitin reaction (Kahn's). Syphilis of the aorta in the colored race is marked by the great extent of the necrotic changes present. This may perhaps account for the great frequency of aneurysm of the aorta among colored persons. Lues of the pulmonary artery was observed in 3 cases of the 1,000. In one of these it was combined with a large aneurysm of the abdominal aorta; in both of the others the changes in the aorta were very slight in comparison with those in the pulmonary artery. In all 3 cases, which exhibited a moderate hypertrophy of the right auricle, luetic arteritis of the pulmonary artery was the cause of death, due to an advanced thrombosis which had led to almost complete occlusion of both main branches.—*Klinische Wochenschrift*, November 7, 1931.

Cardiac Pain and Sudden Death.—Alexander Lambert, writing in the *American Journal of the Medical Sciences* for December, 1931, clxxxii, 6, says that, contrary to the beliefs of both the medical profession and the laity, sudden and unexpected death is but rarely produced by cerebral

hemorrhage. Statistics prove that the great majority of sudden unexpected deaths occur in certain forms of heart disease, but the overwhelming majority of deaths in heart disease are neither sudden nor unexpected. Thrombosis of the coronary artery without rupture of the heart is probably the most common cause of sudden and unexpected death. In discussing cardiac pain Lambert states that most of the theories held concerning it are unsatisfactory. He offers a theory based on many years of clinical observation, which explains cardiac pain logically, and is borne out in each of its separate factors by experimental work in physiology. Pathological anatomy does not offer an explanation of cardiac pain. Experimental evidence strongly indicates that the myocardial muscular tissue is insensitive, and does not cause pain by ischemia or failure of action through anoxemia or degeneration. Cardiac pain is expressed only through the afferent nerves of the sympathetic portion of the autonomic nervous system. The sensory afferent nerves of the heart and aorta originate and run in the adventitia of the first portion of the aorta and of the coronary arteries and belong only to the sympathetic system or the autonomic nervous system. Stretching and overdistention of these vessels is brought about by normal circulatory reflexes which in diseased tissue cause excessive stretching of the aorta before the depressor reflexes bring relief, or by overfilling cause overdistention of arteriosclerotic walls of the coronary arteries. So long as the circulatory reflexes do not upset the equilibrium between the myocardium and its blood vessels there is no pain. When, however, the afferent functions of the nerves are adequately disturbed, or the myocardium is so degenerated that it cannot contract normally under reflex stimulation, the normal increased rise of blood pressure and the circulatory reflexes produce excessive dilatation of the diseased blood vessels and pain results when the heart endeavors to answer the demands for increased work. This theory explains the various clinical exhibitions of pain in coronary infarcts and thrombosis. It also accounts for the fact that in some operations of sympathectomy, even with none of the sensory fibers cut or disturbed, the attacks of pain may entirely cease when the continuity of reflex action is prevented, and the rise of blood pressure does not take place, and on exertion the adventitia of the aorta is not over-stretched to give pain. Experimental evidence strongly indicates that vascular distention is the usual cause of cardiac pain rather than vascular spasm.

The Problem of Stiff Joints—Sir Robert Jones has chosen this subject because the text-

books deal with it in an indefinite way, with the result that unqualified practitioners render stiff joints mobile with success sometimes disconcerting. He lays down a rule, admitting a few exceptions, that a joint stiffened by simple adhesions, whether intra- or extra-articular, should be moved actively or passively, or even forcibly if necessary. A joint stiffened by arthritis should be kept at rest until pain and inflammation have subsided, when active, rather than passive movements should be practised in the absence of weight-bearing. It is essential, therefore, to make a differential diagnosis between the two conditions. As a rule a joint whose movements are limited in *all* directions, is, or has been, subject to arthritis, while a joint is limited in certain directions *only* is not arthritic. In adult tuberculosis an ankylosing operation on the ankle, knee, or hip is justifiable as soon as an accurate diagnosis is made, as it saves time, lessens danger, and secures a firm joint for all time. In treating joints the aim should be to combat all elements which make for stiffness. When a joint has recovered from fracture or mild arthritis, the patient may be allowed to move his joint within a painless area, or the surgeon may employ one single movement in each direction once a day, and then let the joint rest. If ligaments are torn they should be protected from strain until movements can safely be practised. Massage immediately after an injury (before effusion has taken place, checks hemorrhage into the part, relieves pain, and leaves the tissues ready to commence immediate union. If the joint is sprained, elastic pressure should be firmly applied in order to prevent or minimize effusion, and to allow repair of the injured structures. When ankylosis seems inevitable the surgeon should recommend measures which will insure its fixation in the position in which the limb concerned will be most useful and least crippling to the patient. What these positions should be in the various joints the author clearly indicates. Stiffness following fracture is usually only temporary. It should be remembered, however, that a joint stiffens much more readily if it is rested in a fully extended, rather than the slightly flexed, position. In the presence of traumatic myositis ossificans neither massage nor movements should be employed. An arthrodesis near or at the hip-joint will transform a weak painful joint which cannot bear weight to a strong, painless limb. It should be reserved for comparatively young and healthy individuals. It should never be undertaken in the presence of active disease, but should be delayed until at least two years after its cessation. The technique applicable to the various joints is described.—*British Medical Journal*, December 5, 1931, ii, 3700.

LEGAL

INSURANCE—DEATH BY SUICIDE

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

One of the difficult problems which our courts frequently face is that of determining the manner in which an individual's life came to an end, whether by accident, natural causes, suicide or at the hands of another. A large group of interesting cases has been brought before the appellate courts of this State where the issues involved whether a deceased died by suicide or otherwise. The question is of first importance where a contract of insurance contains a clause preventing recovery of the amount of the policy if the assured died by suicide during a specified period of time after the policy was taken out.

Circumstances may combine to make up a picture which, to the average person, would seem to indicate nothing else than that the deceased person took his own life, but yet the law in general will not presume suicide unless the facts afford no other reasonable explanation. A review of the facts of a few of the adjudicated cases will serve to illustrate the application of the rule.

In one case the deceased was last seen alive walking toward a railroad bridge over a culvert, across a stream emptying into Long Island Sound. His body, which indicated death by drowning, was found not far from the bridge a few days thereafter. It appeared that the deceased some years before had been temporarily insane and had been confined for three months in an institution. He had, however, been discharged therefrom as cured. Under the circumstances it was held that since the death might have been caused by either accident or suicide, the law presumes the cause of death to have been accidental.

Another similarly simple case was that of a collection agent who left home one morning in apparently good spirits. He was seen later in the day at his office by a man whom he asked to go with him to Staten Island to make some collections, but who declined. He was never seen alive thereafter, and eight days later his body was found floating in the bay near Staten Island. Examination of the body by a physician revealed no marks of violence or any conditions which would indicate the presence of epilepsy. It was definite, however, that he had lost his life by drowning. The court held that a jury was authorized upon such evidence to say that death was caused solely by accident and not by suicide, even though the case was destitute of direct proof of any accident befalling the deceased,

Somewhat less clear is a case in which an insurance company defended, on the theory that its assured had died by suicide through the use of cyanide of potassium. Upon the trial the plaintiff established the fact of death, and the defendant introduced into evidence a copy of the record of proceedings at a coroner's inquest. The said record showed that the coroner's jury had determined that the deceased had committed suicide by poisoning. No other proof of suicide was given by the defendant's attorneys. The court, on appeal from a judgment based upon a determination that the defense of suicide was established, ruled that the proceedings before the coroner were not conclusive of the matter and were not binding as admissions on the beneficiaries of the deceased's insurance. The court ordered a new trial to permit the insurance company to establish, if possible, by direct proof its defense of suicide.

Another case of death by poisoning is interesting. The plaintiff was the widow of a man who had carried a life insurance policy, and in her attempt to collect thereon litigation had arisen over the so-called "suicide clause." The deceased had registered as a guest at a hotel in the evening, had done some drinking at the bar and then gone to his room. He was found dead the next morning with the door locked on the inside. Three letters written by the deceased were found in the room, one to his wife, one to the chief of police, and one to his employer. However, what was contained in these letters did not get into the trial record. On the bureau was found a box of white powder and a glass containing a sediment. A medical witness testified that he had ascertained the powder and the sediment to be bichloride of mercury. With such evidence before them, the jury decided for the plaintiff against the insurance company, thereby deciding that suicide had not been shown. On appeal the higher court declined to change the jury's determination.

A rather surprising result was reached in a case where the defense was that the deceased died by suicide and where it was conceded that he died from self-administered carbolic acid. The plaintiff conducted her case under the theory that the dose was taken accidentally. The deceased was a barber by trade about thirty-eight years of age. For some time his health had been poor and his eyesight bad, and he had suffered great pain at intervals. It appeared that he was under a

doctor's care and frequently carried medicines with him. Shortly before his death he had bought a four ounce bottle of carbolic acid. He then went into a saloon and ordered two glasses of beer. He took one glass into the washroom, and he came out declaring that he had killed himself and asked for a doctor. A doctor was called but the man soon died. His lips, mouth, throat and stomach were found burned from carbolic acid, and the bottle about a third empty was found upon his person. A letter was also found addressed to his wife, asking her forgiveness and requesting her to take care of the children, and containing the further statement that he could stand it no longer. There was also testimony that he had previously had a revolver permit and that his wife had seen him standing in front of a mirror with the revolver in his hand, after which she had taken steps to have the permit revoked and the revolver taken away from him. Said circumstances spell out a very clear case of deliberate, premeditated suicide, but the appellate court faced with said facts ruled that the evidence was insufficient to permit the court to dispose of the matter as a question of law and that a jury question was presented, and that the jury might reasonably determine that the acid was taken by mistake in the belief that it was proper medicine for the man's illness.

The sort of case, however, that the court will take from a jury and determine as a clear case of suicide, is illustrated by a case of death by illuminating gas. The deceased had sometime prior to her death been operated upon and had there after suffered from hemorrhages, and about two weeks prior to her death she had been discharged by her physician as cured. The evening before her death it was observed by her landlord that "she appeared greatly excited. Her eyes were very glassy in color. Her hair was somewhat disheveled, which was unusual with her, and she said nothing." The next day she was found in her room dead, lying on her bed, with the two gas jets in the room fully turned on. The room was filled with illuminating gas. There was no evidence to show that the supply of gas had been in any way interfered with or that there was any draft which might have extinguished the flames. A gas engineer was called by the plaintiff to testify that there might have been a leak in the gas main which might have caused water to get into the pipes, which might have accidentally put the lights out. On such evidence a verdict was rendered based upon accidental death. The appellate court ruled that the testimony of the gas engineer was improper, being wholly speculative as there was no proof of a single fact upon which his theories as an expert were based. The court, therefore, reversed the verdict as against the weight of all the evidence.

A somewhat different type of case arose where the question to be determined was whether the

deceased had lost his life by suicide or by murder. His body was found early one morning hanging from a rope attached to a railing in a secluded part of a railroad station. Obviously the man had not met with an accident, and his death had been premeditated either by himself or by others. There was nothing to indicate the existence of any signs of a struggle. The spot where the body was found was a place the deceased would not ordinarily visit so that either he went there deliberately to hang himself or he was abducted and taken there by murderers. There was evidence that he had been suffering from pains in the head and had the fear that he might become insane. There was also evidence that he had complained about his family relations. On the other hand, there was no evidence that anyone would have had the slightest motive, even that of robbery, for taking his life. The appellate court definitely ruled that the decision necessarily had to be that the deceased took his own life. The court summarized the principles controlling its decision as follows:

"Upon the trial the burden rested upon the defendant to establish by a preponderance of evidence its defense that the deceased came to his death as the result of suicide. If there was a dispute in the evidence as to the controlling facts or if, there being no dispute as to said facts, the latter were still so inconclusive in their nature that reasonable men might draw different inferences therefrom, an issue of fact was presented which should have been passed upon by a jury. Upon the other hand, it would not have been permissible to allow a jury to indulge in conclusions and deductions which were not legitimately and legally deducible from the facts testified to, but which would be mere speculation and guesswork. No principles have been laid down in any of the recent decisions referred to which in any way destroy or impair such well-grounded rules."

"Keeping such principles in our mind it seems to us that the defendant produced evidence which fairly and legitimately sustains the claim that the deceased committed suicide, and that upon the other hand, to permit a jury to find that he was murdered would be to allow the wildest kind of speculation to pass for legitimate inference."

The law has set up a presumption against suicide, and it seems properly so. It would be extremely harsh if, on mere speculation a deceased person could be branded as having taken his own life and his estate thereby often deprived of the financial benefits of his insurance. Hence the presumption is against suicide, and the party seeking to rebut that presumption must clearly establish that the deceased did in fact die at his own hands. The result is that the cause of death is legally considered other than suicide, unless suicide is the only reasonable conclusion that can be drawn from the proven facts.

ALLEGED NEGLIGENT TREATMENT OF BURNS

A doctor engaged in general practice was called to the home of a man who had accidentally received certain burns about his legs. The doctor was told that the man's trousers had caught fire as a result of the explosion of a stove in which he was starting a fire. The doctor examined the man and found extensive second and third-degree burns on both of his legs and his feet. The doctor immediately suggested that he go to a hospital for treatment, but the patient refused. The doctor then treated the man at his home, using unguentine for an ointment and applying sterile dressings which he changed every twenty-four hours. A large number of blebs developed on the legs and feet, and the doctor opened them as the condition required. The condition of the burns was such that after nine days of treatment at the man's home the burns had not healed but gave indication of infection setting in. The doctor, therefore, insisted on the patient entering a hospital in order that he might have proper nursing care.

The patient accordingly was taken to a hospital where he remained a patient for about five

months. During this period of hospitalization a great amount of slough developed and it was necessary that skin-grafting be resorted to in the treatment of the man's condition. The doctor attributed the infection and slough which developed both to the severe nature of the original injury and the extremely unsanitary conditions in which the patient had lived.

A damage suit was brought against the doctor claiming that as a result of negligent treatment by him the man's injury developed from a first-degree burn to a third-degree burn and caused infection to set in. Contrary to the facts of the case, the patient also charged that the doctor had prevented him from entering a hospital and obtaining proper care for his injury. The case came on for trial and at the close of all the evidence introduced on behalf of the patient, it appeared that he had been unable to produce any proof to the court to show that the doctor in any way departed from proper and approved practice, and, therefore, on motion of the attorney for the defendant the plaintiff's complaint was dismissed.

CLAIMED FAILURE TO PROPERLY TREAT MENTAL CASE

This was an action brought against the defendant, a specialist in psychiatry. It appeared that the mother of the plaintiff came to the office of the doctor and explained to him that her daughter was confined for some mental disease in a sanitarium, asking the physician if he would visit the sanitarium and examine the patient. The doctor went to the sanitarium the following day and was taken to a room in which the patient was locked up. He psychoanalyzed the patient's condition and after an examination advised the family that he thought he might be able to improve her condition. Acting on the suggestion of the doctor, the family brought the patient home.

The doctor saw her almost daily for the next two months at his office, and attempted by psychiatric treatment to eliminate the mental hazards which he felt were responsible for her condition. After he had treated the patient at his office for a short time, the doctor diagnosed her condition as manic-depressive insanity and immediately attempted to treat her along the lines which are proper and accepted for this condition. On one or two occasions the patient was so unruly and restless that the doctor, in his best judgment, prescribed codeine.

After the doctor had seen the patient for approximately two months and she had not improved to any great extent, he advised the family that she be put in some sanitarium as it was evident to him that her condition had so far progressed that he could not effect a cure. The family assented to this and the doctor arranged to have the patient put in a State sanitarium. He never saw her after this.

Sometime thereafter an action was instituted by the patient in which it was alleged that the doctor had failed to use reasonable or proper care in endeavoring to cure her of the malady from which she was suffering, and that he had unskillfully and negligently prescribed certain drugs which were injurious in their nature, all to plaintiff's damage. The action was commenced by the plaintiff herself, but later a motion was made by the plaintiff's attorney to substitute the parents of the patient as her guardians ad litem for the purpose of prosecuting the action. This motion was granted by the court. The parents, however, evidently realizing the futility of the claim of neglect and malpractice, permitted the case to be dismissed on motion of the doctor's attorney, thus terminating the action in the doctor's favor.

NEWS NOTES

PUBLIC RELATIONS COMMITTEE

A meeting of the Committee on Public Relations of the Medical Society of the State of New York was held on July 26, 1932, in the Hotel Roosevelt, New York City. There were present Dr. James E. Sadlier, Chairman; Dr. W. H. Ross, Secretary; Dr. George M. Fisher, Dr. A. J. Hambrook, Dr. T. H. Cunningham, and Dr. O. W. Mitchell. There were also present Dr. F. H. Flaherty, President-Elect; Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education; Dr. J. S. Lawrence, Executive Officer; and Dr. Frank Overton, Executive Editor.

The principal subject of discussion was the relation of the Medical Profession to the State Department of Health and the State Charities Aid Association in regard to public measures for the control of venereal diseases. The specific subject was the interpretation of a circular letter of January 12, 1932, issued by the Committee on Tuberculosis and Public Health of the State Charities Aid Association describing a project for the control of venereal diseases. This project had been adopted by the State Charities Aid Committee at a regular meeting on December 9, 1931, and was as follows:

A Project to Be Undertaken by the State Charities Aid Association, Through Its State Committee on Tuberculosis and Public Health, to Secure Citizen Interest and Support for the Control of Venereal Diseases in Up-State New York

1. *Purpose:* The purpose of this project is to provide the State and local health authorities, in the more intensive work they are about to undertake, with that supplementary interest and assistance which they need from voluntary organizations of public spirited, informed citizens, in order to round out and make their programs of work for the control of venereal diseases increasingly effective.

Medical science in recent years has made a number of discoveries for the detection, treatment and control of these diseases, and real progress can be achieved if this new knowledge is put to use. The problem of the control of these diseases is second only in its social significance to that of tuberculosis in the entire field of public health. Syphilis, which is the most serious of these diseases, is also the best understood scientifically from the point of view of prevention, diagnosis and care.

The tragic happenings that may follow in the train of this disease, if inadequately treated, cannot be overstated. Among them are: many thousands of deaths of infants before birth; thousands of patients in the wards for the incurable and crippled, who sit in wheel chairs year after year, or drag themselves about with feeble and halting steps; multitudes of patients in the hospitals for the insane suffering from a special and extremely serious type of mental and physical breakdown, until just recently always incurable.

On the recommendation of the Governor's Special Health Commission, of which President Farrand of Cornell University is Chairman, and the State Commissioner of Health, Dr. Thomas Parran, Jr., is Secretary, the State Department of Health is about to undertake a more thorough-going effort in conjunction with local health authorities for the control of syphilis and gonorrhea.

The State Commissioner of Health feels that the support of voluntary organizations and of public spirited citizens is urgently needed for this intensive campaign, and he has said that our Association's State and Local Committees on Tuberculosis and Public Health are, by reason of their successful and extensive experience over a period of 24 years in the fields of tuberculosis prevention, health legislation, diphtheria prevention and general health education, the voluntary societies best fitted for participation in such intensive social hygiene work up-State.

The State Charities Aid Association has voted to enter this field of work if special funds for the purpose become available, and a special committee was appointed to formulate a suggested program of work of which the State Commissioner of Health was Chairman, and of which the General Director of the American Social Hygiene Association, Dr. William F. Snow, was a member. The report of that committee has been accepted by the Association, and the program of work recommended by it is set forth below.

The sum of Six Thousand (\$6,000) Dollars is needed by the State Charities Aid Association with which to undertake a modest beginning program in this field.

2. *Program:* Following is an outline of the program, all the items of which supplement the present or proposed activities of the State and local health authorities:

1. To promote the extension to nearby rural communities of the social hygiene clinical facilities that are now available in particular up-State cities.

The State Department of Health would advise our Committee as to what counties or rural areas immediately adjacent to cities are in great need of clinical help.

2. To endorse and secure legislative support for the proposal of the State Health Commission that *State Aid* (at present available for counties only) be extended to *municipal* boards of health as a means of securing the establishment of satisfactory local diagnostic and treatment facilities for venereal diseases.

3. To secure the *help* of the Local Committee on Tuberculosis and Public Health *in improving the organization, equipment and service of local public venereal disease clinics* along the following lines:

(a) Providing funds over a temporary demonstration period for the salary or salaries, in part or in full, of qualified medical personnel, or of a technically qualified public health nurse or nurses, or funds for a qualified epidemiological investigator to search out cases and contacts and to help develop and put into effect new administrative techniques for bringing and keeping "lapsed" cases under effective clinical supervision.

(b) Providing the funds for the *post-graduate* education of locally employed clinic personnel, including physicians, nurses and social workers.

(c) Using their good offices, and funds, if need be, for making the local clinic quarters more commodious, inviting, attractive and better adapted for the efficient performance of the work of the clinic.

This may involve the renovating, painting or papering of the quarters, the provision of suitable floor covering, of furniture, including comfortable chairs in place of hard, stiff-backed benches; pictures and posters for the walls; plants and cut flowers; appropriate literature, magazines and other reading matter for waiting patients.

4. To assist in building up an informed public opinion regarding venereal diseases and the essential measures for combating them. Also to be of service to the State and local education authorities, if desired, in work they may undertake or have in hand in the field of sex-character education in the schools.

5. To endorse and secure legislative support for the State Health Commission's recommendation that the State Health Department be enabled to carry out in at least two areas—one a rural area, and the other an urban area—model programs for venereal disease control.

Endorsement by the State Commissioner of Health: A letter from the State Commissioner of Health, Dr. Thomas Parran, Jr., follows, in

which he endorses this project, and expresses the hope that funds may be secured with which to enable the State Charities Aid Association to undertake it:

"December 28, 1931.

"Mr. George J. Nelbach,
Executive Secy., State Committee on Tb. & P.H.,
State Charities Aid Association,
105 East 22nd Street,
New York City.

"My dear Mr. Nelbach:

"I was very much gratified with the discussion which took place at the last meeting of your Executive Committee, and pleased with the approval given to the report of the special committee appointed to recommend a social hygiene program for the State Committee.

"It is my personal feeling, which I think is shared by many members of the Governor's Health Commission, that our next big advance in public health should come in the control of venereal diseases, and particularly in the control of syphilis. As I have recently read the history of the anti-tuberculosis movement in the State, I have been impressed with the fact that the effort of your Association in this field was started at a time when there was much less scientific knowledge as to specific measures of control for tuberculosis than we have today for the control of syphilis. During the past twenty-five years, tuberculosis has been reduced by one-half.

"I am sure that during the next quarter century even more than that can be accomplished in the control of syphilis if public education and the provision of better medical care for its victims can be stimulated by voluntary agencies in the same way as anti-tuberculosis measures were stimulated. The technics need to be different, but the general purposes are the same.

"I attach considerable significance, therefore, to your decision to enter the social hygiene field, and hope you will find it possible to develop an active program.

"Sincerely yours,

"(Signed) THOMAS PARRAN, JR."

This project had been reported to the Executive Committee of the Medical Society of the State of New York on February 11, 1932, by Dr. J. N. Vander Veer, and referred to the Committee on Public Relations. The Committee on Public Relations had expressed its opinion of the project in a resolution which endorsed its educational features, while opposing the general establishment of clinics. Dr. Sadlier presented the correspondence which he had carried on with Mr. Homer Folks, Secretary of the State Charities Aid Association, in regard to its plans for establishing clinics for venereal diseases. Mr. Folks had referred to clinics already established in

cities, some of which admit cases from the surrounding rural communities. He said that the Association would not establish new clinics in any rural section; but it planned to utilize the existing clinics of some city for the benefit of a rural section around the city, the object being to determine the response of the rural cases and physicians to the clinic, and to develop a practical plan for conducting a clinic in a rural community, if one should be needed.

The Committee considered the excellent work of Dr. N. Vander Veer, who had been appointed a liaison officer to represent the State Medical Society in its relation to the Venereal Disease Division of the State Department of Health. The plans of Dr. Vander Veer had been outlined in a clear and comprehensive report printed in the Journal of June 1, 1931, page 712. A further development of his work is reported in the Journal, describing the method by which any doctor may take a specimen of serum from a suspected carrier for examination by the State Department of Health, thereby greatly promoting the early diagnosis of syphilis. (See page 869 of the Journal of July 15.)

Dr. Ross described the satisfactory development of the work of the Department of Health of Suffolk County by which family doctors were paid by the County for treating indigent cases of venereal diseases. A large element in the success of the work was that the treatments by county departments of health were mandatory under the State Law. The fiscal boards of the counties seem to be willing to assume financial burdens provided the responsibility is imposed on them by the State.

The members of the Committee on Public Relations felt that the methods of venereal disease control are now in a stage of development and evolution, and that the greatest prospect of success lies in the cooperation by the trinity of public health organizations:

1. The Medical Profession.
2. Official Departments of Health.
3. Unofficial Lay Health Organizations, especially the State Charities Aid Association.

The peculiar field of work of the Committee on Public Relations is to study the activities of these three groups of public health workers and to advise their members how they may coordinate their efforts in a friendly way. The Committee has already established a reputation for dealing wisely with all public health workers, and for fair impartiality as referee in public health disputes.

The subject of the private practice of medicine by members of the Medical staffs of the State hospitals, prisons, and other State institutions was discussed. Dr. Ross reported that the attitude of the leaders in the State Department of Mental Hygiene was that the State employs its physicians on a full-time basis; and that any time left over after the performance of their daily duties should be devoted to study, or to recreation, in preparation for the efficient performance of their professional work in the institution. The Committee will consider this subject further as occasion arises.

The Committee considered a letter from Dr. William A. Howe outlining the tentative plans of the State Department of Education for promoting the physical examination of school children through the cooperation of family physicians. The members of the Committee expressed their appreciation of the cooperative attitude of Dr. Howe in consulting the representatives of the family physicians in regard to the proposals of the Department.

The Committee also approved a plan submitted by Dr. W. P. Brown of the Medical Inspection Division of the State Department of Education for promoting anti-tuberculosis work among school children, especially by taking x-rays.

The Committee gave considerable time to the consideration of details of border-line problems which had been referred to it for advice.

The meeting closed with a discussion of methods of reaching the county medical societies, and inspiring their leaders to enter into active cooperation with other health agencies in the local communities. Dr. Sadlier called attention to the great progress which has already been made, one-third of the counties having established cordial relations with the other health organizations during the five years of the existence of the Committee on Public Relations of the State Medical Society.

Dr. Sadlier also called attention to the interest aroused by the district conferences of the chairmen of the County Public Relations Committees, as reported in the Journals of April 1, 1932, page 406, and May 15, page 614. The next meeting of the Committee is scheduled for September 15 in Buffalo, and will include a regional conference of the Public Relations Chairmen of the counties in the western end of the State.

WILLIAM H. ROSS, *Secretary*.

JAMES E. SADLIER, *Chairman*.

The State Department of Health would advise our Committee as to what counties or rural areas immediately adjacent to cities are in great need of clinical help.

2. To endorse and secure legislative support for the proposal of the State Health Commission that *State Aid* (at present available for counties only) be extended to *municipal* boards of health as a means of securing the establishment of satisfactory local diagnostic and treatment facilities for venereal diseases.

3. To secure the *help* of the Local Committee on Tuberculosis and Public Health *in improving the organization, equipment and service of local public venereal disease clinics* along the following lines:

(a) Providing funds over a temporary demonstration period for the salary or salaries, in part or in full, of qualified medical personnel, or of a technically qualified public health nurse or nurses, or funds for a qualified epidemiological investigator to search out cases and contacts and to help develop and put into effect new administrative techniques for bringing and keeping "lapsed" cases under effective clinical supervision.

(b) Providing the funds for the *post-graduate* education of locally employed clinic personnel, including physicians, nurses and social workers.

(c) Using their good offices, and funds, if need be, for making the local clinic quarters more commodious, inviting, attractive and better adapted for the efficient performance of the work of the clinic.

This may involve the renovating, painting or papering of the quarters, the provision of suitable floor covering, of furniture, including comfortable chairs in place of hard, stiff-backed benches; pictures and posters for the walls; plants and cut flowers; appropriate literature, magazines and other reading matter for waiting patients.

4. To assist in building up an informed public opinion regarding venereal diseases and the essential measures for combating them. Also to be of service to the State and local education authorities, if desired, in work they may undertake or have in hand in the field of sex-character education in the schools.

5. To endorse and secure legislative support for the State Health Commission's recommendation that the State Health Department be enabled to carry out in at least two areas—one a rural area, and the other an urban area—model programs for venereal disease control.

3. *Endorsement by the State Commissioner of Health:* A letter from the State Commissioner of Health, Dr. Thomas Parran, Jr., follows, in

which he endorses this project, and expresses the hope that funds may be secured with which to enable the State Charities Aid Association to undertake it:

"December 28, 1931.

"Mr. George J. Nelbach,
Executive Secy., State Committee on Tb. & P.H.,
State Charities Aid Association,
105 East 22nd Street,
New York City.

"My dear Mr. Nelbach:

"I was very much gratified with the discussion which took place at the last meeting of your Executive Committee, and pleased with the approval given to the report of the special committee appointed to recommend a social hygiene program for the State Committee.

"It is my personal feeling, which I think is shared by many members of the Governor's Health Commission, that our next big advance in public health should come in the control of venereal diseases, and particularly in the control of syphilis. As I have recently read the history of the anti-tuberculosis movement in the State, I have been impressed with the fact that the effort of your Association in this field was started at a time when there was much less scientific knowledge as to specific measures of control for tuberculosis than we have today for the control of syphilis. During the past twenty-five years, tuberculosis has been reduced by one-half.

"I am sure that during the next quarter century even more than that can be accomplished in the control of syphilis if public education and the provision of better medical care for its victims can be stimulated by voluntary agencies in the same way as anti-tuberculosis measures were stimulated. The technics need to be different, but the general purposes are the same.

"I attach considerable significance, therefore, to your decision to enter the social hygiene field, and hope you will find it possible to develop an active program.

"Sincerely yours,

"(Signed) THOMAS PARRAN, JR."

This project had been reported to the Executive Committee of the Medical Society of the State of New York on February 11, 1932, by Dr. J. N. Vander Veer, and referred to the Committee on Public Relations. The Committee on Public Relations had expressed its opinion of the project in a resolution which endorsed its educational features, while opposing the general establishment of clinics. Dr. Sadlier presented the correspondence which he had carried on with Mr. Homer Folks, Secretary of the State Charities Aid Association, in regard to its plans for establishing clinics for venereal diseases. Mr. Folks had referred to clinics already established in

working in city clinics, clearance of compensation cases for arbitration, practice of medicine by corporations purporting to render medical service, neighborhood health development, illegal practice, city comfort stations, examination of pre-school children, electric light rates, and the change in the sanitary code with regard to laboratories.

The Subcommittee on Radio Broadcasting of the Committee on Public Health reports the completion of its first year of work as of the first of July. Weekly broadcasts have been given over WBBC, a considerable number of broadcasts over WCGU and announcements with regard to diphtheria have been broadcast recently over these two stations as well as over WLTH and WAIL.

The Committee on Public Health in cooperation with the Health Department is urging greater activity with regard to diphtheria immunization—particularly in the Fort Greene health area.

The Milk Commission and the Special Committee on Certified Milk appointed by the Council have arranged trips to farms, conferred with producers; and in various ways even conducted more than the usual activity required by the routine of certification.

The Cancer Committee has practically completed arrangements for cancer study as a cooperative effort between the County Society's Committee on Public Health, the Cancer Committee, and the Brooklyn Cancer Welfare Service.

The Fall Series of the Friday Afternoon Practical Lectures scheduled to begin in October have been completed by the Clinical Committee. The subjects and the speakers to discuss the same promise much of interest and value to every practitioner of medicine.

The President of Kings County, as a subcommittee of the Coordinating Committee, with a group of advisers representing the Five County Societies, has been considering the Municipal Hospital Law and the report of the plan for further study of the relationship of the profession to Municipal Hospitals—particularly in connection with remuneration for services rendered when the patient was in a position to pay for professional service received—especially in compensation cases.

The President-elect, in getting ready for 1933,

has already begun to plan the work for his committees and make committee appointments. In June his Scientific Committee held its first meeting to map out programs for the coming year. The January and February programs are all laid out.

The routine activities of the Society in the Library, through the information service, and the like, continue without abatement.

The hospital and dispensary question has been quite a feature in medical discussion and action during the month. The President of the Medical Society of the State of New York, the Chairman of the Committee on Public Health of the County Society, and the Secretary of the Coordinating Committee of the Five County Medical Societies attended an all-day conference of a group working on the medical phases of the problem of neighborhood health development in preparation of a program for presentation to the representatives of the County Medical Societies to the Committee on Neighborhood Health Development for discussion and final recommendation.

The Director of Medical Activities has been appointed a member of the Committee on Nomenclature in Uniform Staff Organization of the American Hospital Association. The Chairman of this Committee is Mr. Boris Fingerhood, Superintendent of the Israel-Zion Hospital. Mr. Fingerhood was recently elected President of the New York State Hospital Association.

The Hospital Medical Library

Our Librarian, Mr. Charles Frankenberger, has given this subject a lot of thought during the past years, has helped many of our members with their hospital library problems and prepared a paper entitled "A Suggested Hospital Medical Library" and an exhibit for the last Clinical Congress of the American College of Surgeons. This article—with its carefully prepared lists of journals, books for a minimum working library and a suggested list for expansion will answer the questions of any hospital staff library committee—appears in the June, 1932, issue of the *Bulletin of the American College of Surgeons*. (See page 971.)

JOSEPH RAPHAEL, Reporter.

THE AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

The recognized sources of authority in the several specialties are the national organizations of their practitioners, a list of which is printed in alternate numbers of the *Journal of the American Medical Association*. The issue of July 23, 1932, contains the announcements of over fifty special societies whose scope is nation-wide.

A meeting of a national medical organization of interest to physicians of New York State is that of the American Academy of Ophthalmology and Otolaryngology to be held September 19-23, 1932, in Montreal, Canada. Dr. Arthur J. Bedell of Albany is the Chairman of its Committee on Publicity and Legislation.

THE DAILY PRESS

MUTE, INGLORIOUS MILTONS

Whatever theologians and psychologists may say about foreordination and freewill, heredity and training, most unsuccessful persons feel that they could become presidents or millionaires if they cared to do the unpleasant things that famous persons have to do in order to achieve

I never need to chide myself
Because my futile labors
Have brought me in no store of pelf
Like that of my rich neighbors.
That poverty has been my lot,
That hopes of wealth evade me,
I know is due alone to what
Heredity has made me.
That I cannot in box or vault
A heap of gold sequester,
I'm certain, is alone the fault
Of some remote ancestor.

My loathing for all forms of toil
Is not of my own making,
Nor is the fact that I recoil
From any undertaking.
I take no blame for being poor
For, back in ages hazy,

success. Moreover the unsuccessful are prone to say that their ill luck is a family trait.

James J. Montague writing in the New York *Herald Tribune* of August 5, expresses the plaint of the inglorious majority in the following verses, which contain more truth than poetry.

Some relative of mine, I'm sure,
Was slack, and loose and lazy.
From men I cannot even name
My troubles I inherit,
But I refuse to take the blame;
It's they who have to bear it.

While other men have done high deeds
I've tipped the foaming seidel;
While they have served their country's needs
I've been remiss and idle.
While they have made their names renowned
And spent their waking hours
In splendid works, I've sat around
And wasted golden hours.
The fact that I am not today
A governor or senator
And crowned with wealth and fame, I lay
To some remote progenitor.

DEATHS FROM VIOLENCE

The *Herald Tribune* of August 4 has an editorial on "Careless America" which says:

"The National Safety Council has published a lugubrious and instructive booklet, called 'Accident Facts,' by which the average American may learn how much more careless the average American is than anybody else. From the booklet's forest of statistics let us glean a few significant branches.

"No other country in the world that keeps any records is as rich in mechanical marvels as we are or as utterly careless in preventing them from hurting us. Our death rate from accidents is three times that of the safest country, Denmark, and considerably more than that of our nearest competitor, Canada—where, in spite of proximity and example, they have not yet learned to throw life away as fast as do we."

After discussing railroad accidents, drownings, and other forms of so-called accidental deaths, the editorial writer takes up the subject of automobile fatalities and says:

"The death rate from automobile accidents has been steadily increasing, while that from all other causes has been going down. Possibly because we spend so much more time in automobiles, we have less opportunity to drown, to be bitten and to fall downstairs than formerly.

"When you, as a passenger, step aboard a regular, scheduled commercial plane you will (statistically speaking) be killed only if you fly from coast to coast once a week for fourteen years, while each year one American out of every four thousand inhabitants is killed by an automobile.

"It seems as if the air were safer than the ground after all. And it is tragically and irrefutably certain that if a fraction of the effort expended in making the air safe were applied to the road, booklets such as 'Accident Facts' would not be so thick, or such melancholy proof of the incredible unwillingness of Americans to take elementary care of either their neighbor's life or their own."

CREDIT PLAN FOR MEDICAL FEES

The New York *Times* of July 21 contains a half column account of the operation of a mutual association of one thousand physicians and dentists of New York City, incorporated for the purpose of enabling patients to pay their professional advisors on the installment plan. The article says:

"A patient needing treatment signs an agreement with his physician or dentist, whom he selects himself, for the total amount of the fee. The association then advances to the physician 50 per cent of the amount and the patient pays it back on a monthly installment plan, in accordance with his income, at a receding interest rate of 6 per cent, amounting to \$2.75 for each \$100 if paid in ten months. The physician or dentist pays a collection and service fee of three-quarters of one per cent a month for the period of the note, amounting to \$7.50 for each \$100 on ten monthly installments. The patient is relieved of the burden of paying the entire fee at one time and thus is made to feel that he can afford the treatment. The physician is assured of his fee and is spared the task of collecting his own bill.

"Physicians have found that only 50 per cent of their patients remember to pay them in full, 20 per cent pay them in part and 30 per cent do not pay at all.

"On the other hand, 98 per cent of the patients who have agreed to pay on the installment plan have paid their doctors and dentists in full.

"The entire transaction is handled at the doctor's office, and the patient is not required to get co-signers on his note if he is a wage earner or has any other source of income. Many wealthy persons, inconvenienced by the depression, are availing themselves of the service, however, a majority of the patients are small wage earners and their families."

Commenting on the plan the New York *Herald Tribune* of July 25 says editorially:

"Enigmatically sensible—so sensible that one wonders why it was not thought of and put into effect long, long ago—is the plan whereby doctors will collect their fees in installments, via a central agency. About a thousand dentists, physicians and surgeons in New York have become members of such an organization, to which we wish success. It is a two-way plan, offering relief to both parties involved on the following basis: The patient, before sitting in the dentist's chair or lying on the operating table, agrees upon the amount of the fee, signs a note and pays it off in monthly installments geared to his income, plus interest of 6 per cent, to the central agency, which in turn advances immediately to the physician one-half the total amount of the fee.

"Such a plan would cure—at any rate, alleviate—the peculiar and unusually highly irregular financial relations of patient and physician. Doctors do not like to be demanding, as theirs is a vital service which should always be given, when really necessary, regardless of reward. And the public is incredibly lax and mean where doctor's bills are concerned, putting them at the bottom of the monthly pile, delaying them a good part of the time or never paying them at all. It always seems harder to pay for repairs than for acquisitions, and patients—unless they are visibly the richer by a handsome set of gold teeth—dislike parting with money for a state of health which they feel should be theirs by natural right.

"It is to be hoped that the plan will succeed as it deserves and be extended until the most important service one man can perform for another is on a basis at least as secure and accepted as the ownership of a vacuum cleaner or an electric icebox."

CREDIBILITY OF POPULAR SCIENCE

The alleged discovery of a live toad embedded in the masonry of an old wall inspired the following editorial in the *Herald Tribune* of March 13, 1932, on the subject of accuracy in observations:

"Among the thousands of relics of prehistoric man, the vast majority have had their scientific value ruined utterly because they were dug out hastily by inexperienced and ignorant bystanders, who destroyed what evidence there may have been of such vital

matters as original burial and age. What to do until the doctor comes may involve positive prescriptions. What to do with mysterious finds until the trained scientist comes is always negative.

"Do nothing. Let no one touch anything at all, until experience and trained observation are on the ground. Were this injunction universally known and observed, many facts even more interesting than the truth about buried toads might be saved to science."

BOOK REVIEWS

HANDBOOK OF TROPICAL FEVERS. By N. P. JEWELL, M.D., D.P.H. and W. H. KAUNTZE, M.D., D.P.H. Octavo of 485 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$6.00.

The authors, who write from their experiences in Kenya, a British possession in the eastern central portion of Africa, state that they have considered three classes of the medical profession,—the student, to supply the basic facts of tropical diseases, the practitioner in the tropics, who needs a handy reference book and the physician in temperate climates, who may be called upon to treat these diseases in patients who have been abroad. The methods which the authors have themselves found to be the best, are the ones described in the most detailed manner. Some of the diseases described, will of course not be met with in a lifetime, by practitioners in these parts, but it is very convenient to have so reliable a reference book with clinical data and laboratory facts combined.

Among the chapters on diseases most often seen by local physicians are those on Heat Exhaustion and Stroke and Cerebro-Spinal Fever, and there are some diseases described, which though uncommon here, are of much importance and interest, as they may be encountered but easily overlooked, at any time. Among these are Amoebiasis, Bacillary Dysentery, Psittacosis, Typhus, Tularemia, and Undulant Fever.

There are many observations of interest noted. With regard to Cerebro-Spinal Fever, the authors state that sub-conjunctival hemorrhages in the lower fornix of the conjunctiva are almost always present and are practically pathognomonic.

W. E. McCOLLOM.

SURGERY OF THE CHEST. By GEORGE F. STRAUB, M.D., F.A.C.S. Octavo of 475 pages, illustrated. Springfield, Charles C. Thomas, 1932. Cloth, \$10.50.

This book can be read with a great deal of interest and profit by most of the profession when we consider the tremendous advance in the surgical treatment of pulmonary tuberculosis. In the opening of his book the historical background and evolution of Thoracic Surgery is very lucidly and competently given by Dr. Straub. Although most of the common problems of chest pathology are discussed in the book the most practical portion is that given over to pulmonary tuberculosis. A commendable trend of conservatism is apparent in this book, always admirable in any new surgical contribution.

The rarer problems of mediastinal, esophageal and cardiac surgery are discussed, but, considering their rarity it does not have the same practical importance.

The book is unusually well illustrated.

E. J. GRACE.

THE WAY OF HEALTH INSURANCE. By A. M. SIMONS and NATHAN SINAI. Octavo of 215 pages. Chicago, The University of Chicago Press (c.1932). Cloth, \$2.00. (Publications of the Committee on the Study of Dental Practice of the American Dental Association: No. 6.)

The Committee appointed by the American Dental Association to cooperate with the Committee on Costs of Medical Care felt the need of definite information on health insurance. Most important was the lack of adequate information concerning the human relationships involved. With the American College of Dentists they provided the fund to make the investigation which is reported in this book. They only required the subject to be impartially studied and presented. To remain impartial, not swerved by the existing accounts and reports must have been a difficult task. There is a dearth

of literature on all phases of the subject. The articles and books are numbered in the thousands but there are few, very few, free from bias. Health insurance is not State Medicine, the authors show us, because "the physicians and dentists in insurance are not government employees; nor does it obtain its main support from taxation." In that sense there is no State Medicine in Europe.

How health insurance is obtained in different countries, how it grew from the lodges, clubs, workingmen's societies to its place of government recognition, regulation and political advantages, how the funds are raised, how the doctor or dentist is remunerated by single service fee, by fixed salary or by per capita fee for each person on his panel, are here concisely and clearly stated.

It does not suffice for a few doctors to know much about this subject, nor for many to know a very little about it. We can never forget that in the present inequitable distribution of this world's goods, many people in this country cannot secure and do not receive all the necessities of medical care, and what they do receive is principally from the charity of the medical profession. Until that distribution is right plans and laws for health insurance are and will be proposed in the legislatures of many states, and every doctor should be qualified to help in the enactments, the control and the direction of these health activities.

This book of 210 pages deserves reading by every doctor, whether or not he *thinks* he has interest in the subject, and the authors and dental profession deserve for it rightly merited appreciation and praise.

THOMAS A. MCGOLDRICK.

THE COSTS OF MEDICINES. By C. RUFUS ROREM, Ph.D., C.P.A. and ROBERT P. FISCHER, B.S., Ph.D. Octavo of 255 pages. Chicago, The University of Chicago Press (c.1932). Cloth, \$2.50. (Publications of the Committee on the Costs of Medical Care: No. 14.)

The authors of this book have presented in a most interesting and attractive way, facts and opinions that are of value to all Physicians and Pharmacists and would serve a good purpose if brought to the attention of the public.

The dependence of the Physicians upon the Pharmacist, even in these days of changing methods of treatment and use of remedies that are administered by other than the prescription method and the ability of the Pharmacist through experience and because of the additional knowledge gained in more extensive compulsory college courses, to meet the most delicate and exacting requirements of the Physician, is admirably and consistently set forth.

The detrimental effect upon the general practice of Medicine that is occasioned by inconsiderate, habit forming methods of ordering and directing the use of remedial agents, that is explained in such plain and convincing terms, should have the serious consideration of all Physicians for a decided change in some of these methods will prove to be one of the most effective means of curbing the much discussed and condemned self medication.

The need for thorough cooperation between Physicians and Pharmacists in a determined effort to protect the public by decreasing the number of persons that, through ignorance, rely upon commercial advertisements, rather than ability, training and education for their medical treatment, is fully covered.

The statistics contained in this book emphasize the need for such cooperation.

The costs of medicines as they apply to the charges made by the Physicians and Pharmacists are fully justified by the statements and records of this publication
WILLIAM C ANDERSON

DISEASES OF THE KIDNEY By W GIRLING BALL, FRCS and GOREFFREY EVANS, M.D., FRCP. Octavo of 424 pages, illustrated Philadelphia P Blakiston's Son & Co, Inc, 1932 Cloth \$7 50

Blakiston presents a four hundred odd page book about the kidney, written by a surgeon and a physician. It is about three parts surgery and one part medicine. The authors, particularly Dr Evans quote quite freely from the German and American literature, but in the main the book follows the English tradition. The two aspects of renal disease are well presented. The preface promises a "view point of a physician and surgeon in close collaboration". From this standpoint the book is disappointing. Perhaps another edition will do more to remind the physician how many times the mechanical skill and special knowledge of the urological surgeon will benefit his patients, and tell more of the real medical problems that beset the operating urologist.

TASKER HOWARD

METHODS AND PROBLEMS OF MEDICAL EDUCATION (Twentieth Series.) Quarto of 250 pages, illustrated New York, The Rockefeller Foundation, 1932

The Twentieth Series of this publication, issued in April 1932 is as usual very attractive and of excellent typographical make up. Much of the space is devoted to the Medical Schools of Yale and the American University of Beirut. A fine article on The Place of Preventive Medicine in the Medical Curriculum is reprinted from Public Health London. It would be well if subsequent volumes could be devoted to that most important subject
CHARLES A GORDON

GROWTH AND DEVELOPMENT OF THE CHILD. Part III Nutrition. Report of the Committee on Growth and Development, KENNETH D BLACKFAN, M.D., Chairman. White House Conference on Child Health and Protection. Octavo of 532 pages. New York, The Century Company (c1932) Cloth, \$4 00

Whether one gets satisfaction from this book depends on what he is seeking. If he opens it, expecting from its one word title and its source, that it will be a simple or a complete guide to Infant Feeding, he will be woefully disappointed. The amount of direct value to a general practitioner or a pediatrician in his practice is but slight.

However, if he reads a few lines that "nutrition implies, for present purposes, a study of the food substances and of the bio chemical processes which utilize them" and that is what he wishes, this book is an excellent presentation, not only of protein, carbohydrates and fats and the vitamins but also of Iodine Amino Acids, and the more and the less common minerals.

Moreover, in addition to what it tells, the Bibliography is extensive and you can go as far as you wish to original sources
W D LUDLUM

THE INSANITY PLEA By EDWARD HUNTINGTON WILLIAMS, M.D. 12mo of 169 pages. Baltimore. The Williams & Wilkins Company, 1931. Cloth, \$2 00

Throughout the law the question of insanity as a defense has always been a problem. Particularly since the time of the McNaughton case, law and medicine have been struggling to meet on a common ground, for apparently the concept of legal responsibility as understood by law and medicine is hard to harmonize.

Doctor Williams in an interesting manner discusses insanity as a defense. It is the result of his own experiences. In no manner is it a text book. The question of insanity as a defense is raised and discussed in the light of our medical information.

It is interestingly written
GEORGE I SWETLOW

BIOCHEMISTRY IN INTERNAL MEDICINE. By MAX TRUMPFER, Ph.D. and ABRAHAM CANTAROW, M.D. Octavo of 454 pages, illustrated. Philadelphia, W B Saunders Company, 1932. Cloth, \$5 50

The material presented in this book represents a good introduction to the interpretation of biochemical phenomena in internal medicine. The authors have devoted very little space to a description of technique in laboratory methods, but have on the contrary, devoted most of their efforts to a clinical evaluation of all biochemical methods. Their descriptions take on a didactic form and frequently eliminate controversial interpretations. The chapter on carbohydrate metabolism contains a description of the physiology of glucose utilization, significance of post-absorptive blood sugars, sugar tolerance tests, including glucose, levulose, and galactose, and a chemical differential diagnosis of the various glycosurias including dextrose, lactose, levulose, pentose and galactose. There is a chapter on protein metabolism containing a description of normal nitrogen metabolism and of clinical phenomena associated with the presence of pathological nitrogen constituents of nitrogen in blood and urine. Chapters follow on cholesterol, chloride, calcium and phosphate metabolism. A good part of the book is devoted to a discussion of the laboratory findings in diabetes, nephritis, nephrosis, hepatic disorders, gastric and pancreatic function.

The authors deviate from their general procedure by including descriptions of a number of methods employed in the study of hepatic and gastric disorders. They close with a valuable chapter on chemico-clinical differential diagnosis in which the important metabolic disorders are recorded with a listing of all the pathological chemical changes that are encountered in each of these diseases.

On the whole, the book is written in clear, simple style and is well organized. It is devoid of a bibliography and is intended to be a practical presentation of the subject to the student and physician.

WILLIAM S COLLENS

TEXT BOOK OF MASSAGE AND REMEDIAL GYMNASTICS. By L. L. DESPARD. Third edition. Quarto of 474 pages, illustrated. New York, Oxford University Press 1932. Cloth, \$6 00 (Oxford Medical Publications.)

In writing this third edition the author has given a work not only to the physio-therapist but also to the orthopedist.

A brief survey is made of the histology and physiology of the skin, muscles, cartilage and bone.

The work contains three chapters of beautifully illustrated anatomical plates covering every important detail of the skeletal and muscular systems, followed by a like chapter on the nervous system.

Massage movements are thoroughly dealt with including effleurage, stroking, massage a friction, petrissage, tapotement, vibration and shaking.

This is followed by two chapters describing the most modern methods and technique on Swedish remedial gymnastics.

Following this is worthy information to the orthopedist considering our recent epidemic of acute anterior poliomyelitis, namely, the re education of muscles, beginning with the facial, neck, and including all the groups in the body, then the correction of residual deformities is taken up thoroughly, including the various spinal deformities.

A good deal of ground is covered on the various deformities of the feet both congenital and acquired.

The final chapters deal with materials to be used in administering treatments such as compresses types of bandages and electrical apparatus.

The work is worthy of study by those who may prescribe as following sprains, fractures, paralysis, deformities and nerve lesions
JOSEPH H NEVINS

OUR NEIGHBORS

HEALTH ADMINISTRATION IN ARKANSAS

The June issue of the Journal of the Arkansas Medical Society contains the minutes of the 1932 House of Delegates, filling twenty-four pages, of which eight are on the relations of physicians to the State Department of Health and local administrators, including public health nurses. The subject was introduced in the report of the Committee on Health and Public Instruction of which the State Health Officer, Dr. C. W. Garrison, of Little Rock, is chairman. In regard to corrective clinics, Dr. Garrison reports:

"The early corrective clinics, usually tonsil and adenoid clinics, were not inspired nor organized by the health authorities, nor by members of the medical profession. They came about more or less logically as the result of a desire of the interested mothers of the State to have the children suffering with correctable defects given medical and surgical attention. An investigation on the part of the State Health Officer revealed that in almost every instance where clinics were organized by lay individuals unscrupulous and incompetent physicians were called in to do the surgical work.

"There is no law to prevent such a procedure. It, therefore, was felt that the only proper and logical agency was the State Board of Health. The following definite instructions were issued years ago and have been restated in writing and verbally many times.

"That the clinic is to be held only with the approval and under the auspices of the county society. In the counties where there are no societies, the practicing physicians control.

"That under no circumstances should the health personnel select the specialist or operator, this being left entirely with the county society, or physicians interested.

"That the physical examinations made by the health personnel shall not be accompanied with a diagnosis, but referred to the physicians for further determination.

"That a notice be sent to the parents directing that they confer with their family physicians.

"That reasonable fees be charged in accordance with the family's ability to pay.

"That it not be called a free clinic and the price each individual pays should be regarded as confidential.

"Clinics operated in this manner have afforded surgical service to thousands of seriously affected children who otherwise could not have received this service. Many others able to pay and did, and who have benefited by this service, probably never would have received this attention.

"The effect of these clinics has been to educate the parents to the necessity of having their children examined and corrections made when necessary, which has resulted in an increasing number going to the private physicians for examination and treatment."

Regarding free immunization, the report says "The Law directs that the State Board of Health make investigations as to the cause, prevalence, and distribution of communicable diseases and take such steps as may be necessary to ameliorate the same.

"The trained health officer is a specialist in the prevention of disease just as in any other branch of medicine. It, therefore, would seem that immunization of all classes against small pox, typhoid and diphtheria would be the duty as well as the professional privilege of the health authority.

"The medical profession of Arkansas is divided on this question. A number of the county societies, as well as many physicians outside of the societies, feel that it is not only the duty of the health authorities to do this work, but that it offers great relief to the medical profession in caring for many who will not or do not pay for the service, and ultimately results in increasing revenue due to stimulation of general desire for the service. On the other hand, another group is actually insistent that this practice is an infringement on the rights of the general practitioner and tends to alienate the public from the old established custom of depending on the private physicians for medical care, or in other words, tends to promote State medicine.

"This fact must not be overlooked, however, namely, that there is an increasing demand on the part of the public to have general immunization against the above enumerated diseases. A spirit of fair play and full cooperation must obtain on the part of the medical profession. This applies not only to the immunization question, but involves a prompt reporting of notifiable diseases to the health authorities, the filing of birth certificates, the signing of death certificates, and proper instructions to the patient and family members as to the proper precautions to avoid infection. The responsibility reaches even further than this. Hygienic and sanitary environment is a matter which should concern every physician; he, more than anyone else, can contribute to the improvement of the same."

The three associates of Dr. Garrison gave a written report opposing the non-pay feature of

(Continued on page 990—adv. xii)

It's QUICK ACTION

PREVENTS DEFORMITIES—

NO antiricketic substance will straighten bones that have become misshapen as the result of rickets. But Mead's Viosterol in Oil 250 D can be depended upon to prevent ricketic deformities. This is not true of all antiricketic agents, many of which are so limited by tolerance or bulk that they cannot be given in quantities sufficient to arrest the ricketic process promptly, with the result that the bones are not adequately calcified to bear weight or muscle-pull and hence become deformed.

A Specific for Rickets

Mead's Viosterol, on the other hand, is capable of terminating the ricketic process in a brief period in virtually every type of case. Thus if given as a prophylactic in requisite dosage it may be expected to prevent not only bowing of the legs but also the more insidious skeletal defects such as malformation of the chest, hypoplastic teeth, and pelvic abnormalities, which may develop unnoticed when less effective vitamin D products are administered.

Especially Indicated for Prematures

Prematures, twins, infants of low birth-weight, and rapidly-growing, full-term infants are especially susceptible to ricketic deformities because of their greater need for calcium and phosphorus. Yet the first three types of infants, due to their small digestive organs, are generally unable to take even the usual dose of cod liver oil, much less increased doses. For them Mead's Viosterol is specific in preventing malformations just as it is in all other types of rickets.

Mead's Viosterol is packed in brown bottles and light-proof cartons to prevent rancidity and deterioration. Unique dropper-stopper is a convenience and avoids waste.

Because of its potency Mead's Viosterol prevents and cures rickets . . . in small dosage . . . without gastric upset . . . quickly . . . before deformity sets in.

**Don't Confuse
Maltcao
with ordinary
chocolate drinks**

So far as is known, Maltcao is the only
chocolate food drink with added or-
ganic salts of calcium, iron and phosphates.

During pregnancy and lactation, when diets of high
calcium and phosphorus content are required to
permit more rapid calcification of the growing body,
Maltcao is a nearly perfect food.

Maltcao is especially recommended for
Expectant Mothers. Nursing Mothers.
Growing Children. Convalescents.
Athletes in training. The aged.

Cases of "nerves" and insomnia and for many per-
sons under severe mental or physical strain.

BUILDS FOR THE YEARS AHEAD

(Continued from page 988)

the clinics and immunizations. In the discussion
Dr. E. H. Hunt said:

"The wholesale mutilation of children in the
public schools, etc., is to be condemned by all of
us. He says the State Office isn't back of that.
The county health nurse in my county said she
was instructed to attempt to get up such a clinic
in Johnson County. The doctors in Johnson
County didn't back her in any way nor will we.
So far there have been no clinics and there will
not be any in Johnson County wherein the doc-
tors are connected with it. The nurse tells me
she has been in service for several years, and
before coming to Johnson County, she thought
the doctors should do the immunization, but she
had been instructed to do it. Dr. Horner of
Coal Hill said she knocked him out of \$600
during this past year.

"In Morrilton the other day, the county health
nurse received patients right there in the court-
house. The State Board of Health undoubtedly
knows about all this, and it is directly antagon-
istic to the doctors of the State of Arkansas."

Dr. C. E. Dungan said:

"Aside from the financial part of vaccination,
I don't believe the doctors will ever starve to
death because they don't get to vaccinate chil-
dren. I personally would like to get rid of that
part of my practice. I have helped to conduct
some clinics, especially following the flood of
1927, for typhoid immunization. The thing that
I saw that I thought was the most hazardous thing
about vaccinating against typhoid was the use of
those serums that may produce a reaction where
there was a lack of understanding of the physical
fitness of the patient to be vaccinated. I noticed
so many nurses, and even have seen some doctors,
give typhoid vaccination to tuberculars that pro-
duced a very profound reaction, and in some
cases, I thought, caused a reactivation of the
condition, a reaction that produced active tu-
berculosis when otherwise it may have become
quiescent. I think that is to be condemned, be-
cause the nurses are not acquainted; they give
little children the same size doses as adults."

A committee on an investigation of public
health administration had been working for a
year and submitted a report which said:

"During the investigation much objection was
found to the activities of the health agencies.
The activities objected to may be briefly stated
as follows:

"1. The free immunization of large numbers
of people against typhoid and diphtheria with-
out attempting to differentiate between those able
and those unable to pay for such services.

"2. The activities of unsupervised County
Health Nurses.

"3. The practice of curative medicine by full-
time salaried health officials.

(Continued on page 991—adv. xiii)

(Continued from page 990—adv. xv)

"4. The conducting of tonsil-removing and other clinics without consultation with physicians resident in the locality where the clinics are held.

"Of these, the greatest part of the objection was to the immunization program, and a minor part of the actual practice of medicine by health officers and nurses, and the manner in which the clinics were conducted.

"In fairness to the health authorities it was found that in certain counties the health work has been approved by the county medical society. The committee is convinced that these counties are in the minority.

"The reasons given above, the resentment of physicians to the activities of the health authorities in some of the counties of the State, is a real menace to all of the health program. It is further convinced that this resentment is growing rather than subsiding.

"We believe that plans should be perfected by the Board of Health whereby the physicians of the different counties may, if they wish, have active participation in any health program that is instituted. We believe that the physicians can be utilized in the examination of school and pre-school children for remedial physical defects. We would recommend that, in those counties, where objection has been raised to the wholesale immunizations by health nurses, this work be done by the physicians.

"Your committee would recommend that county medical societies actively participate in the management of tonsil-removing and other clinics. We think that there is a demand for such clinics and other clinics, and that they will be held regardless of whether the physicians of the county participate or not. To this end it would be wise for each society to establish general rules providing for such clinics and give publicity to them for the guidance of Parent-Teacher and other interested organizations. As outlined by its Secretary, your committee has not found any defects in the policies of the Board of Health for management of such clinics."

Dr. Garrison and his associates made a supplementary report which embodied the suggestions of the Council and proposed a plan for the cooperation of the medical profession with the Department of Health in regard to clinics. The essential features of the plan are as follows:

"Since conditions vary widely in different sections of the State as to population, accessibility, economic status and adequacy in number of physicians, that the plan be modified to meet the needs of each county as determined by the physicians therein and the State Board of Health.

"That every effort be made by the health personnel under the direction of the State Board

SARATOGA HATHORN MINERAL WATER

A Natural Saline Laxative

STATE OWNED AND STATE BOTTLED

SARATOGA Hathorn No. 2 is a naturally carbonated mineral water possessing mild purgative qualities. A relatively high content of magnesium bicarbonate and the presence of sodium chlorid, the alkaline bicarbonates and carbon dioxide gas make it extremely effective.

Saratoga Hathorn mineral water has proved beneficial in hyperacidity occurring in cases of acid catarrh of the stomach. Especially favorable results have been obtained in cases of dyspepsia due to mental over-exertion. Saratoga Coesa is an even milder saline laxative.

All Saratoga mineral waters are bottled just as they flow from the ground, under careful State supervision. The valuable catalytic activity of Hathorn and Coesa are retained in bottling by the complete exclusion of oxygen.

Upon written request, we will gladly send a complete analysis and a complimentary carton of Saratoga mineral waters for clinical tests, including 2 bottles of Geyser and 1 bottle each of Hathorn and Coesa.

Announcing Digismith—

A NEW NAME AND A NEW PRICE ON
AN OLD, ESTABLISHED PRODUCT

UPSHER Smith Digitalis, long known to the medical profession as the hallmark of digitalis quality, a product that is grown and processed under the closest personal supervision on the Upsher Smith Digitalis Farm, now costs no more than any other good digitalis preparation on the market.

Reduction in List Price

Reduction in Prescription Cost

Note these radical reductions in cost to you and your patient:

Reduction in List Price from \$9.00 a dozen (75c a bottle) to \$7.20 a dozen (60c a bottle)

Reduction in Prescription cost of 20%

You can now get International Unit Security at Cat Unit Price—thus, Upsher Smith Digitalis is not merely biologically assayed in terms of absolute Cat Units, but it is checked against the International Standard Digitalis Powder of the League of Nations. In this way the margin of error associated with biological assay is reduced to the minimum and the dosage can be more rationally determined.

NOTE: In future, products of Digitalis Purpurea (Upsher Smith) will be marketed under the name **Digismith**.

Digismith is available in three forms:

Tincture (1 oz. bottles)

Capsules ($\frac{1}{3}$, $\frac{3}{4}$ and 1 International Unit)

Tablets ($\frac{1}{2}$, $\frac{3}{4}$ and 1 International Unit)

Let us send you a clinical trial package of **Digismith** with our compliments.

Upsher Smith Co.

of Health to keep the physicians advised as to the health program.

"That the State Society requests and urges its members to cooperate to the fullest extent in promoting the health program, and where possible attend and participate in any clinics or group meetings occurring in their community.

"That publicity precede the holding of immunization clinics, setting out that they are to be held for the benefit of those who are unable to pay for same and that all be urged to secure immunizations from their family physicians.

"That the County Society be requested to authorize one or more of its members to be in attendance.

"That the State Society request the physicians of each county to fix a nominal immunization fee for those unable to pay the regular professional fee and offer free service to those who are unable to pay, and that biologicals be furnished the physicians through the local health personnel at the State Board of Health contract price for the under-privileged group.

"That all physicians fill out record cards to be furnished by the State Board of Health and filed with the local health personnel as a matter of permanent record for school use and other purposes.

"That corrective clinics—orthopedic, eye, ear, nose and throat; fact-finding, etc. be held in accordance with the prescribed policy of the State Board of Health as approved by the Council."

This report was unanimously adopted as the public health policy of the Arkansas Medical Society.

GRADUATE COURSES IN WISCONSIN

The June issue of the *Wisconsin Medical Journal* has the following description of a course in Pediatrics, sponsored by the State Society:

"An attractive opportunity for taking a post-graduate course in Pediatrics near at home will be offered by the Society this summer to physicians in the southeastern counties. A six weeks' course will be conducted at five centers under the leadership of Dr. Wayne A. Rupe of Washington University, St. Louis, Missouri.

"This is another in the series of post-graduate courses which have been sponsored by the Society in cooperation with the University of Wisconsin Medical School and the University Extension Division.

"The meetings will begin during the week of July 11 in the following cities:

"Milwaukee (2 classes), Racine, Waukesha, Kenosha, Burlington.

"The meetings in each center will be held on the same day each week and at the same hour and

(Continued on page 993—adv. rv)

(Continued from page 992—adv. xiv)

place. The arrangements for each group will be determined with reference to the desires of the greatest number of physicians registering. All registrants will be informed well in advance concerning these local arrangements.

"1. Discussion relative to newer methods of prevention and treatment of certain contagious diseases.

"2. Discussion of newer ideas about the breast feeding and the artificial feeding of the normal infant through the first year of life.

"3. Causes and treatment of the various types of infantile colic, including the so-called nervous colic. Diagnosis and treatment of pylorospasm, pyloric stenosis.

"4. Causes, prevention, and treatment of diarrhea in infancy. Treatment of the premature and immature baby. Treatment of the marasmic.

"5. Treatment of infantile skin diseases, eczema, the diaper rash, etc. Treatment of asthma. General discussion of the tonsil and adenoid problem.

"6. Treatment of pyelitis, enuresis, nephritis, and nephrosis. In discussing clinical cases the handling of many physical diseases as well as the handling of psychic disturbances and behavior problems will be taken up. The following disturbances will be touched upon: breath holding, nervousness, intestinal parasites, anorexia in older children, the underweight child, thumb-sucking, convulsions, etc."

EX-PRESIDENTS' CLUB OF MISSISSIPPI

The June issue of the New Orleans Medical and Surgical Journal contains the following account of the Ex-Presidents' Club of the Mississippi State Medical Association.

"One of the interesting side-lights of the State Medical Association meeting was the annual banquet of the ex-presidents. This took place at 12:30 on Wednesday in the Tea Room of the Robert E. Lee Hotel, where an excellent chicken dinner was served. The chairman presides in the order of sequence. Dr. D. J. Williams of Gulfport, president in 1912, was the presiding officer. After dinner, Dr. Williams called on a few of the members for remarks beginning with Dr. P. W. Rowland, Oxford, president in 1895, and the oldest member present. Dr. Rowland has been a member of the State Medical Association for 49 years, and has attended nearly every meeting. Four years ago at the organization of this club, he issued a challenge to the ex-presidents to meet him every year for the next ten years. He certainly looks good for the balance. Chairman Williams next called on Dr. John C. Culley of Oxford, as the youngest ex-president, his term of office expiring with this meeting. Dr. Culley is an old Jackson boy, son of our Dr. B. L. Culley, and has made good as an executive officer

A delicious food-drink for high-calory feeding

Fortified by Vitamin D

Licensed by the

Wisconsin Alumni

Research Foundation

COCOMALT is a delicious, high-calory liquid food, especially recommended during pregnancy and lactation, during illness and convalescence, and for malnourished children.

Prepared according to directions, Cocomalt adds 110 extra calories to a glass of milk—increasing its food-energy value more than 70%. Provides extra proteins, carbohydrates and minerals (calcium and phosphorus)—and contains not less than 30 Steenbock (300 ADMA) units of Vitamin D per ounce.

Comes in powder form, easy to mix with milk, HOT or COLD. In ¼-lb., 1-lb. and special 5-lb. size. Reasonable in cost.

Free to Physicians

We will send a trial can of Cocomalt, free, to any physician requesting it. Just mail coupon.

Cocomalt

"Cocomalt is a scientific food concentrate of barley malt extract, selected coconuts, skimmed milk, sugar, whole eggs, flavoring and added Vitamin D."

ADDS 70% MORE NOURISHMENT (FOOD-ENERGY) TO MILK
(One ounce per glass or cup)

R. B. DAVIS Co., Dept. 71J, Hoboken, N. J.

Please send me a can of Cocomalt without cost or obligation.

of the association. Dr. W. S. Leathers, formerly dean of the Medical Department of the University of Mississippi, and for many years executive officer of the State Board of Health, now dean of the Medical Department of Vanderbilt University, was next called upon and made a very enjoyable talk. Dr. James M. Acker, President-Elect, whose administration begins at the close of this meeting, was next called. He expressed his appreciation for the honor conferred upon him and asked the advice and assistance of his fellow club-men in carrying out the work of the new year. Another veteran, Dr. H. H. Haralson of Vicksburg, president in 1896, was called on and responded with some reminiscences of former days.

"This is the fifth meeting of the Ex-Presidents Club, which has shown a remarkable attendance, the last three years showing the high water mark of 80 per cent present. Considering their ages and residences in many states, this certainly is a remarkable showing of continued interest on the part of the ex-presidents, and should be an example well worthy of emulation by the younger members."

MENTAL HYGIENE IN PENNSYLVANIA

The Medical Society of the State of Pennsylvania has a Committee on Medical Hygiene. Dr. J. Allen Jackson is Chairman. The objects of the Committee are set forth editorially in the May issue of the *Pennsylvania Medical Journal* as follows:

"1. Arrange programs on mental hygiene before:

"(a) County medical societies, stressing neuroses and psychoneuroses this year.

"(b) The woman's auxiliary of each county medical society.

"(c) Parent-teacher associations, federated clubs, service clubs, etc.

"(d) Radio audiences, by encouraging and promoting the broadcasting of mental hygiene subjects in the central and western sections of the State under the auspices, respectively, of the Dauphin and Allegheny County Medical Societies.

"(e) Medical readers, by preparing editorials for the *Pennsylvania Medical Journal* on Mental Hygiene and Psychiatry.

"2. Arrange, if possible, for one paper on mental hygiene before the General Session of the Medical Society of the State of Pennsylvania, and for a combined symposium on surgical and psychiatric problems, before either the Section on Surgery or the Section on Medicine.

"3. Request county, municipal, and State men-

(Continued on page 995—adv. xvii)

(Continued from page 994—adv. vii)

tal hospitals, institutes, and schools to arrange a clinic for the county societies in their hospital or school district at the hospital, school, or institute.

"4. Stimulate our medical colleges to the need of further practical training of medical students in psychiatry through clinical and didactic lectures and during internship training

"5. Procure the cooperation of our general hospitals in treating certain bordering cases.

"Speakers for such a program may be procured through the cooperation of the Pennsylvania Mental Hygiene Committee of the Public Charities Association and the members of the Mental Hygiene Committee of the State Medical Society, which has augmented its membership to include all neuropsychiatrists in the eastern, central, and western sections of the State"

JOURNAL OF CALIFORNIA

The June number of *California and Western Medicine* contains the minutes of the House of Delegates of the California Medical Association, held on May 2, 1932. The finances of the Journal are described by the editor as follows:

"During recent years, in round figures, the advertising income was as follows: In 1928 the advertising income was \$34,830; in 1929 (when the Journal advertising rates were raised 20 per cent) the advertising income reached \$40,098 (a gain of \$5,268); in 1930, was \$37,070 (a loss of \$3,028); in 1931 (our present fiscal year), was \$33,561 (a loss of \$3,509)."

The treasurer reported on the finances of the Journal as follows:

"The income of *California and Western Medicine* from advertising was \$33,561.19; \$3,500 less than in 1930 due to cancellation of advertising contracts; from subscriptions (including allocated county society dues of \$9,803), \$12,440.50; and from miscellaneous income, \$180, making total income \$46,181.64.

"The expense of Journal production and distribution totaled \$28,653.81; selling expense, \$5,802.39; salaries of the editors and one-third of the clerical force, and miscellaneous general expense amount to \$15,252.10; a total of \$49,708.30. Journal loss of \$3,526.61, a loss somewhat less than the direct loss in advertising for that year."

The budget of expenses that was adopted included the following items for the Journal:

Salaries, editorial	\$7,400.00
Salaries, clerical (one-third that of the office staff)	2,435.00
Publication expense	30,000.00
Commissions to local advertising agent	3,500.00
Commissions to A.M.A. Cooperative Advertising Bureau	2,500.00

WHAT IS MALTCOA?

Maltcoa is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables. See page xii.—*Adv.*

VICHY CELESTINS

The American Agency of French Vichy, Inc., sole American agents of "Vichy Célestins" water bottled at the Spring at Vichy, France, owned by the French Government. There are other

Springs at Vichy also owned by the French Government such as Grande Grille and Hôpital which are imported by these Agents but these are not sent here in as large quantities as the "Vichy Célestins." This Agency also imports the Vichy Salts and Vichy Pastilles which are called Products of Vichy-Etat because they are made from the Salts extracted from the waters of these government-owned Springs. Medical Profession of the United States annually sends many patients for the treatment of diseases of the stomach, liver, etc.—See page v.—*Adv.*

GOLF, AND INFANT FEEDING

It is possible to play over the entire course with a single club and bring in a fair score. But playing with only one club is a handicap. The best scores are made when the player carefully studies each shot, determining in advance how he is going to make it, then selects from his bag the particular club best adapted to execute that shot.

For many years, Mead Johnson & Company have offered "matched clubs," so to speak, best adapted to meet the individual requirements of the individual baby.

We believe this a more intelligent and helpful service than to attempt to make one "baby food" to which the baby must be adapted. See page xi.—*Adv.*

ARTIFICIALLY INDUCED FEVER IN THE TREATMENT OF DISEASE

By C. M. CARPENTER, Ph.D., AND S. L. WARREN, M.D., ROCHESTER, N. Y.

From the Department of Medicine, Division of Radiology, of the University of Rochester School of Medicine and Dentistry, and Strong Memorial Hospital, Rochester, New York. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 25, 1932.

DURING the last five years a few groups of investigators have undertaken an intensive study of fever as it occurs naturally during the course of an infectious disease, as well as that type artificially induced for therapeutic effects. Although there has been a decided change in the attitude of physiologists and physicians towards the value of fever, its significance is still not appreciated. During the vogue of the administration of febrifuges, a body temperature elevated above normal was considered as a passive factor, and the result of an increased heat production of no particular value. Because of the disagreeable sensations experienced by the patient, antipyretics were prescribed in an attempt to make him more comfortable. Such practice is still customary with certain physicians. Cases of extreme hyperpyrexia should so be treated, but the rationale of physical means of dissipating the heat seems superior to the use of drugs. In our present concept of fever we should consider it to be a natural active factor produced within the body to aid in destroying an infectious agent and to repair tissue injury from any cause. Fever is undoubtedly as important as phagocytosis, or antibody production, in the defense mechanism of the body. Furthermore, it may be fundamentally concerned with, or responsible for, the other processes associated with the production of a local or general immunity.

Although the exact cause of increased heat production, or of decreased heat loss, is not well understood, much information has been accumulated concerning its effects. Dubois¹ has studied the results of fever on metabolism, and has shown that, in general, the rate of metabolism follows van't Hoff's law; namely, that for every 10° C. rise of body temperature there is a 13% increase. The effect of temperature on phagocytosis is most interesting. Commandon² made moving pictures of leucocytes and noted that they creep faster

from 30° to 35° C. than from 25° to 30° C. At 25° C. he observed them to travel 9.6 microns per minute, while at 35° C. they moved 25.2 microns per minute. As the temperature of the body becomes elevated above normal, the physical property of the leucocyte changes from the gel toward the sol state, thereby becoming more permeable and able to ingest greater numbers of bacteria or other foreign particles. We have observed from the hourly examination of cervical smears an increased phagocytosis of gonococci during the course of an induced fever. Fenn,³ who analyzed the data of Madsen and Watabiki⁴ on the effect of temperature on the phagocytosis of bacteria, showed that the rate of phagocytosis is very nearly a logarithmic function of temperature.

One of the most significant effects of fever temperatures is its destruction of infectious agents by heat within the body. The more susceptible a virus is to changes in the temperature of its environment, the shorter the thermal death-time. We have studied the effect of fever temperatures on the spirochæte of syphilis, the gonococcus, and the tubercle bacillus, as well as on many other micro-organisms. It was found that *Treponema pallidum* is killed in vitro by a fever of 39° C. in five hours, by 40° C. in three hours, by 41° C. in two hours, and by 41.5° C. in one hour. The gonococcus was more resistant, but some strains were destroyed in five hours at 41.5° C. which, for the most part, is the exposure used by us in our clinical studies. Other strains were destroyed in from six to eight hours at 41.5° C., but a study of the hourly death rate as determined by reductions in plate counts showed that 99.9% of the organisms were killed during the first two hours at this temperature. At the lower fever temperatures (40° and 41° C.), the thermal death-time was correspondingly longer. The tubercle bacillus, however, is still pathogenic

for guinea pigs after two hundred hours' exposure to 41.5° C.*

Certain chemical changes in the blood constituents are affected by fever temperatures. Nasset, Bishop, and Warren⁵ observed in dogs that, with an increased respiratory metabolism, the CO₂ content of the blood was decreased, the blood sugar concentration fell rapidly, while the non-protein nitrogen concentration was increased. Other changes in the red and white cell count have been noted during fever, but different observers have reported dissimilar findings. The interpretation of such data is difficult because of a certain blood concentration due to fluids lost in the body during fever therapy.

There are five general methods for producing fever in man for therapeutic purposes: Radiant heat, hot water baths, foreign proteins, infectious agents, and the use of electrical energy. All of these methods depend upon heat, which must either be produced by and within the body, or supplied from without by some form of energy that is transformed to heat when applied to the body. The first is the use of radiant heat by exposure to hot air, with a temperature that can be withstood by the skin of the body. The air surrounding the body may be heated in various ways, but in all cases arrangements must be made to prevent heat losses. Many experiments on heating the bodies of animals by this method have shown that such a method is practical, although the peripheral structures of the body are heated first, and the heat is then conducted to the enclosed viscera.

The second method consists of conducting heat to the body by the use of hot water baths. The hot water not only elevates the body temperature, but the immersion also prevents heat losses. This method is impractical if the fever is to be maintained for several hours. Certain men have stated that this method is very depressing to the patient. Furthermore, the prolonged hydrostatic pressure from without may cause passive congestion of the abdominal viscera.

The injection of foreign proteins for stimulating febrile reactions in man is a common practice. Sterile milk, tuberculin, killed cultures of various micro-organisms, especially *B. typhosus*, and many other proprietary preparations are used with various degrees of success. The uncertainty of these agents in producing fever is well known, and, as a rule, they do not produce sufficient elevation of body temperature to be of great value. A second disadvantage is that toxic substances are frequently introduced, especially when vaccines are used, which may be injurious to the patient. The inability to control reactions that may follow such injections is a third undesirable factor.

The use of living infectious agents for the treatment of dementia paralytica, especially the

work of Wagner-Jauregg⁶ with *Plasmodium malariae*, has greatly encouraged the study of fever therapy. *Spirocheta morsus muris* and *Spirocheta recurrentis* have likewise been used for the fever treatment of paresis. Although the use of these agents has proven of value, their administration is accompanied by those disadvantages resulting from the use of foreign proteins described above. Their effects are uncertain, may be difficult to control, and likewise are disease-producing.

The employment of electrical energy for producing generalized fever is most desirable. We have used two methods that have been designated as "diathermy" and "radiothermy." Frequently both are designated as "high frequency" methods, and the induced elevation of body temperature is termed a "high frequency fever." Some men use the term "ultra high frequency" to differentiate radiothermy from diathermy. We employ the term "diathermy" for the method in which large, flexible, block tin electrodes are bound anteriorly and posteriorly over the thorax of the patient, and a high frequency current (300 meters) is passed through the body. Due to the resistance of the body to the passing current, heat is produced locally between the electrodes, and is conducted through the other tissues of the body by the circulation of the blood.

We designate "radiothermy" as the method used for the heating of the body in a field of short radio waves that are "broadcasted" from two condenser plates. The energy is derived from a short wave (30 meters) oscillator, designed especially for this method of heating. We have previously described this equipment and method. The heating in radiothermy depends upon the same fundamental principle as described above in the case of diathermy, except that the radio waves induce electric currents within the body from which the heat is produced. The accepted theory of heating is that the body furnishes resistance to the conduction of current between the surfaces adjacent to the opposed plates. At each alternation of polarity of the plates, the corresponding polarities are induced upon the adjacent boundaries of the interposed body, and current is conducted through the material for a brief interval.

Satisfactory fevers may be produced with either method. No specific effects with either procedure have been demonstrated, other than heating. However, in the case of the short wave oscillator, greater heating is possible at certain frequencies, depending upon the conductivity of the body or solution to be heated.

The advantage of diathermy over radiothermy is primarily one of economy. The short wave oscillator is more complicated and expensive equipment. The use of radiothermy is more comfortable for the patient because he is free to move about in the chamber used to prevent heat loss, and his respiratory movements are not inter-

* These observations on the tubercle bacillus were made by Peter Cohen, part-time Research Fellow in the Division of Radiology.

ferred with as in diathermy, where electrodes are bound to the chest. The body is more uniformly heated in a field of short radio waves. Burning of the skin is possible with both methods. If, during a diathermic treatment, the edges of the electrodes are not in direct contact with the skin, arcing occurs. When the patient is restless the electrodes may become maladjusted with the same result. If measures are not taken to prevent the accumulation of excessive sweating on the body of a patient treated with radiotherapy, the concentration of short waves in the drops of sweat and the resultant heating cause burning of the skin. We experienced some difficulty with this factor when we attempted to maintain in a patient a fever of $+1.5^{\circ}\text{C}$. for five hours.

In our experience the nursing care has been simpler with diathermy than with radiotherapy. However, this disadvantage is one that can be readily overcome by rearranging the equipment to suit our needs. The use of either of these electrical methods for the production of a therapeutic fever is superior to any of those previously mentioned. The advantages are obvious. The height of the temperature can be controlled at will by increasing or decreasing the amount of energy supplied, or by adjusting whatever arrangement is used to prevent heat loss. Moreover, no toxic substances are introduced within the body.

Previous to our studies on the production of fever in man, considerable time was spent determining the maximum body temperature that can be withstood safely by animals. It was observed that 42.5°C . was safe for normal dogs, rabbits, and guinea pigs, if the temperature was not maintained at this level for more than five hours. Similar observations on man indicated that a rectal temperature of 41.5°C . was safe for a five-hour interval, providing, of course, the patient was not suffering from some severe lesion of the cardiovascular system, the kidney, or the lung. In some instances a temperature of 41.5°C . has been maintained in our patients for seven hours. Occasionally the rectal temperature has registered 42°C ., but for only brief intervals during the treatment.

Description of Methods Used in Diathermy and Radiotherapy

The nude patient is placed in a celotex box, which prevents heat loss. He lies on a mattress that fits into the lower half of the box. The upper half is shaped like an octagon and is 18 inches shorter than the lower half, being hinged to the lower half over which it fits tightly. The patient's head is allowed to project through a semicircular opening in the short end of the upper half of the box. Eight carbon filament lamps are placed in the cover (the upper half) to heat the air enclosed to a temperature of from 45° to 50°C . This compensates for the loss of heat from the body through radiation.

Block tin electrodes, 28 cm. \times 46 to 60 cm., are bound by a many-tailed surgical binder to the anterior and posterior thoracic wall. The electrodes are then connected to a diathermy machine with a capacity to pass 5,000 to 6,000 milliamperes through the patient's trunk between the electrodes. The lights in the box are turned on, and a recording rectal thermometer is inserted. The pulse, respiration, and blood pressure are taken before beginning the treatment. The pulse and respiration are taken at ten-minute intervals during the treatment, as well as the rectal temperature, to check the recording thermometer. The blood pressure is taken as frequently as necessary.

When the temperature has reached 41.5°C ., which requires from one hour and twenty minutes to two hours, the current is turned off. The electrodes are removed from the trunk of the patient, and he is left lying in the box with the air temperature kept at a level sufficient to prevent a lowering of the body temperature. The patient's rectal temperature is maintained at a practically constant level of 41.5°C . for five hours.

At the end of the fastigium of the fever, defervescence is accomplished by opening the cover of the cabinet and exposing the body to a current of cool air blown across it with an 18-inch oscillating electric fan. The body returns to normal in from two to three hours. As the fever subsides, the pulse and respiratory rate likewise return to normal.

The procedure used for radiotherapy is similar. The cabinet for the patient has to be constructed differently to prevent energy losses and burns from metals should they come in contact with the patient. The shape of the box is practically the same as that used for diathermy. The condenser plates are built within the side walls of the box, being covered externally and internally with celotex. The patient lies on a hammock of interlaced tapes or on canvas, so that there is an air chamber below, as well as above, the body. Warm air is circulated around the body to evaporate the sweat during the treatment. The cabinet may be placed on top of the oscillator, or be adjoined to it as a separate unit, which necessitates longer leads, thereby decreasing the input of energy for the patient. One cannot use a recording thermometer in such an electrostatic field; therefore, rectal temperatures are taken with a mercury thermometer at ten-minute intervals during the treatment. The current must be turned off to make this observation.

Before patients are subjected to fever therapy, it is important that a very thorough physical examination be made. This is especially true in arthritis, where a possible focus of infection may be discovered and easily removed, providing relief without such therapy. When it has been determined that the patient is a suitable risk for fever therapy, the general preparation is as follows: A cleansing soapsuds enema is given the night before

the treatment. The patient is allowed to have his breakfast, and two hours before the treatment two grams of sodium bromide are given per mouth. As soon as the patient's temperature begins to rise, 0.325 grams of chloral-hydrate are given per mouth. If the condition of the patient demands more sedative, 0.650 grams of chloral-hydrate are given two or three hours later. Some patients require no sedative, while others require more than prescribed above. Considerable experience with various narcotics has demonstrated that none are very satisfactory for this purpose. Deep narcosis is undesirable. The most satisfactory effect results from the amount of sedative that causes short naps and tends to overcome apprehension, giving the patient the impression of a brief fever period. Almost all drugs cause a preliminary period of excitement before the desired narcosis. They likewise depress respiration and blood pressure. Normally, in the absence of drugs, a delirium is frequently noted, especially between 40° C. and 41° C.

Warm fluids, such as hot water, tea, milk, etc., are given the patient ad libitum during the treatment. Fluids are forced, if necessary, to replace losses from perspiration. After the treatment is over, cold fluids are given per mouth, and cool currents of air aid in lowering the temperature to normal. The temperature of the patient should be normal before he leaves the treatment room, and observed at hourly intervals for a period of four hours after he has been returned to the Division. We desire to have ambulatory patients remain in the hospital for twenty-four hours after treatment.

Occasionally we have found it necessary to discontinue the treatment. This has been due, usually, to a low blood pressure. Cyanosis of the fingers and lips, as well as a beginning pallor about the mouth, serve as a warning of inadequate peripheral circulation. At first the blood pressure (systolic and diastolic) rises slightly with the temperature, but when the fastigium, 41.5° C., is reached it usually declines, and, if there are no complications, is rather uniform throughout the fever period, registering a systolic of from 80 to 70 with a diastolic pressure of from 60 to 50 millimeters of mercury. Occasionally lower levels have been recorded, with no serious results. Frequently the diastolic sound may be heard to zero. In one or two instances it has been necessary to discontinue the treatment because the patient became unmanageable, and more sedative was contra-indicated. Decreasing respiratory rate is frequently a warning sign. The temperature may rise rapidly, due to the failure of the blood and other tissues to be cooled by the inhalation of air at room temperature.

This type of fever therapy is distinctly a hospital procedure, and requires experience to insure safety and as much comfort as possible to the patient. Some patients complain considerably

about the severe heat, while the more intelligent patients tolerate the treatment very satisfactorily. A very competent nurse is extremely important and can save the physician in charge of such therapy much valuable time. A quiet, darkened room, well isolated, is preferable.

Types of Diseases Treated and Results

The type of disease treated for the most part has been that of a chronic, afebrile nature with a high morbidity. A few of the patients have been incurable. In general, they have been those who have failed for several years to respond to other types of therapy. The majority of those subjected to induced fever therapy were suffering from either dementia paralytica, sub-acute or chronic gonorrhea, or arthritis. A few miscellaneous cases, such as multiple sclerosis, tumors, encephalitis lethargica, and undulant fever, have been treated.

Our results in the treatment of paresis have been very gratifying. The percentage of complete remissions and improved cases compares favorably with results obtained from chemical and malaria therapy^{8, 9 and 10}. The most significant difference is the decrease in the percentage of deaths, which, with diathermy and radiotherapy, is much smaller than that observed in other forms of therapy. Perhaps the best results have been obtained with cases of gonococcal infection of the lower birth canal. Many cases that received chemical treatment for comparatively long periods before fever therapy, and had a long series of cervical smears positive for *Neisseria gonorrhea*, became negative after one treatment at 41.5° C. and remained negative except when reinfection occurred. The fever treatment of arthritis has, in some cases, been very striking, while in others no improvement could be noted. The infectious or rheumatoid arthritis has, in general, responded best to the use of high frequency fevers. Gonococcal arthritis has usually resulted in cures, although in one case there was complete failure even after seven hours at 41.5° C. It was determined later that the thermal death-time of the gonococcus, isolated from the joint in this case, was much longer than the fever given the patient.

Too few cases of other diseases have been treated to make statements concerning the value of such treatment. One important improvement shown by nearly all cases is a gain in weight of from 20 to 30 pounds.

To date, 180 treatments over a period of about two years have been given to 122 patients. Only two fatalities have occurred. We, therefore, do not consider the risk greater than that from an abdominal surgical operation. The first fatality occurred in the second patient of the series treated. She was a 25-year-old colored girl, who had recently recovered from an alcoholic psychosis. She was suffering from syphilis of the central nervous system. After an hour at 42° C. (rectal

cause there is quite an amount of pheochrom tissue present in connection with the sympathetic nervous system, outside of the adrenal gland proper.

The function of an endocrine gland can be determined by various methods:

1. By preparation of extracts or isolation of the active principle, the properties of which are established by the usual physiological procedures.
2. By removal of the gland in animals and observation of the deficiency symptoms.
3. By clinical and morbid anatomical observation of cases in which nature supplies experiments often so much more illuminating and clear cut than some of the too artificial laboratory procedures.

The effect of medullary extracts and their potent principle: adrenalin or epinephrine has been the subject of exhaustive studies ever since Oliver's and Schaefer's time in 1894, yet many new facts are constantly brought out by the efforts of physiologists and biochemists. It is impossible to do justice in a brief survey to the wealth of interesting information available. All I can attempt to do here is to enumerate some of the salient points.

Adrenalin is produced and discharged under stimulation of the sympathetic nervous system and its main effect seems to be the stimulation of the sympathicus and of those organs or tissues which function under sympathetic control. Yet the effects produced by adrenalin are dependent upon a great many other factors which if overlooked are likely to obscure the picture. The effect of adrenalin is determined first of all by the medium which carries it to the tissues. Changes in the pH, in the electrolyte or lipoidal content of the blood accentuate or depress, occasionally even invert the effects produced by adrenalin. The susceptibility of the various tissues to adrenalin stimulation also varies considerably, as the result of the momentary state of nervous tension and according to physico-chemical conditions which might be the result of functional, nutritional or pathological changes.

Under ordinary physiological circumstances adrenalin elicits contraction of the heart muscle, the smooth musculature of blood vessels with exception of the coronary arteries, and most of the other smooth musculature with the exception of that of the bronchi and intestines. The latter relax as the result of adrenalin action. Whether adrenalin is instrumental or even active in the maintenance of normal vascular tonus, has been questioned by many physiologists. Clinical and pathological evidence, however, strongly supports such a contention.

Besides its effect upon muscular tonus and circulation, the most striking effect of adrenalin is its relation to carbohydrate metabolism. Injection of adrenalin, particularly if given subcuta-

neously, mobilizes sugar from its depots, increases the amount of the blood sugar, and may yield glykosuria. The antagonism between adrenalin and insulin is one of the most striking physiological observations of recent years. It seems that the injection or increased discharge of insulin, while depressing the bloodsugar level, elicits an increased discharge of adrenalin which thus prevents the development of hypoglycemia. A deficiency of bloodsugar invariably occurs if insulin is injected into animals the adrenals of which had been removed or were incapacitated by sectioning of the splanchnic nerves or ligation of the adrenal veins. The proper balance of carbohydrate metabolism thus depends upon a harmonious concerted function of pancreas and adrenal glands.

Search for the active principle of the adrenal cortex remained longer unsuccessful. In 1907 Lohmann demonstrated the presence of large quantities of cholin in the adrenal cortex and I showed experimentally 20 years ago that cholin is actually discharged from the adrenals through their veins upon stimulation with pilocarpin. Yet cholin did not relieve the symptoms of adrenal insufficiency and thus did not fulfill what the adrenal cortical hormone was expected to do. Various authors abroad had demonstrated during the last 5-6 years that remarkable physiological effects could be obtained with the use of crude cortical extracts. In 1927 I succeeded in isolating the cortical hormone by a method similar to that previously used with success for the isolation of insulin. I suggested the name *interrenin* for this hormone. Subsequently other authors who were engaged in similar research obtained the same substance by using the same or somewhat different methods of extractions. They have described *interrenin* under various other names such as *cortin*, *corticin*, *interrenalin* or *cortical hormone*.

Interrenin is indispensable to life. It relieves the symptoms of adrenal cortical insufficiency and is capable of resuscitating animals practically moribund after removal or destruction of their adrenal cortex. In view of the fact that our knowledge of *interrenin* dates back only a few years, the information available about the various physiological properties of this hormone is still scanty. We know, however, that it is instrumental in relieving muscular fatigue; it is a potent factor in the processes of oxidation in the tissues. It affects nitrogen and sulphur metabolism. It regulates fat and particularly cholesterol metabolism and it bears some still quite obscure relationship to the function of the sex glands. In regard to adrenalin a definite antagonism of these two hormones seems to exist which relates to their effect upon blood pressure, cardiac action and fat metabolism, but apparently does not prevail in connection with some of their other activities.

All these data were made available by experiments in which interrenin or similar cortical preparations were injected into adrenalectomized animals or administered to patients suffering from cortical insufficiency.

Removal of both adrenal glands in animals produces symptoms of disturbed metabolism, low blood pressure, anoxemia and an initial rise followed by a terminal fall of temperature. Destruction of the glands by pathological processes is by no means rare and gives us the opportunity of studying adrenal insufficiency on homo under conditions more illuminating than in laboratory experiments. The most striking form of acute adrenal insufficiency is that due to hemorrhage which is quite frequent in the newborn, but occurs also in older children and occasionally in adults. Thrombosis of major blood vessels with subsequent anemic or hemorrhagic necrosis of the glands is observed in infectious conditions. More often do we find, particularly in pneumonia, circumscribed areas of softening with diffuse degenerative changes of both cortex and medulla. The clinical symptoms accompanying such impairment vary according to the extent of the lesion and to the rapidity of its development. Another factor to be considered is that of age. Hemorrhagic destruction of the glands in the newborn elicits a syndrome which I have called pseudo-pneumonia neonatorum. The striking clinical picture consists of: rapid respiration suggestive of pneumonia yet with negative chest findings, high temperature and occasionally petechiae on the skin. Examination of the blood reveals a low blood sugar and increased urea nitrogen. The clinical symptoms in older children or adults in sudden destruction of the adrenals are often identical. The respiratory embarrassment, however, may be less accentuated, particularly if the lesion of the cortex is not quite diffuse.

An altogether different clinical picture, well known, under the name of Addison's disease is obtained if the destruction of the gland develops slowly and gradually, mostly due to chronic caseating tuberculosis, occasionally to gummatous or other inflammatory lesions. Without trying to describe a syndrome which is extensively discussed in every textbook, I want to enumerate but the cardinal features of this disease; loss of muscular power leading to complete adynamia, bronzing of the skin with pigmentation of mucous membranes, low blood sugar, high blood nitrogen and low blood pressure. It is impossible to definitely establish which of these symptoms are due to deficient phaeochrome function and which to disturbance of cortical activity. It so seems, however, that low blood pressure and blood sugar as well as hyperpigmentation depend upon lack of adrenalin secretion and decreased sympathetic tonus, whereas most of the

other symptoms seem to result from cortical impairment.

It stands to reason that besides complete or almost complete adrenal insufficiency, a good many cases occur in which cortex, medulla or both are affected to a minor degree and in which some of the symptoms mentioned stand out while others are not noticeable. The recognition and diagnosis of such cases confront us with the same difficulties as that of the form frustes of diseases affecting other endocrine glands.

The only way of recognizing these obscure conditions is by thorough study of the patient, according to the principles of modern endocrinology. We shall have to take into consideration all the facts which are experimentally or clinically ascertained as consequences of insufficient adrenal function. Foremost among these symptoms is asthenia, loss of weight, gastro-intestinal pain and functional disturbances, anemia, low blood pressure, hypoglycemia and increased sugar tolerance. The basal metabolic rate may or may not be affected. Lymphocytosis is present as a rule, sometimes with eosinophilia. Occasionally, higher figures for Urea N. and creatinin are obtained. Pharmacological tests with adrenalin or some of the alkaloids used in such tests show abnormal response.

Symptoms of adrenal insufficiency, to a less striking, but certainly not negligible extent are noticed in infectious conditions. A fall in blood pressure, accompanied as a rule by low blood sugar, indicates a decreased sympathetic tonus which is apparently accounted for by an injury of the adrenal medulla. Many a case of so-called cardiac failure in diphtheria, pneumonia and other acute infections could be identified as peripheral circulatory failure brought about by adrenal medullary insufficiency. Rapid respiration and other evidence of anoxemia observed in pneumonia, but also in other acute infections are directly referable to a lack of interrenin as a result of adrenal cortical failure. Muscular weakness, adynamia in acute infectious or toxic conditions or as the symptom of a chronic ailment is equally indicative of cortical failure. Pathological leanness, that is the inability to deposit fat, is often observed jointly with asthenia, fatigueability, low blood pressure and low blood sugar as the result of adrenal failure including medullary weakness and cortical insufficiency. Extreme cases of this kind which occasionally develop in adolescents or children were characterized by the appearance of precocious senility. The French and British authors who observed the first cases of this type described them under the name of progeria.

Besides hypofunction of either or both components of the adrenal gland the occurrence of hyperfunction of the same tissues is also to be expected. Hyperfunction of the adrenal medulla,

or the pheochrome tissue at large is present whenever an excess of these tissues is formed by some pathological process. I have reference in particular to the tumors of the pheochrome system, which are accompanied by a very characteristic syndrome in the majority of the cases observed. The outstanding symptom is high blood pressure which from time to time shows further excessive increase. This paroxysmal hypertension is accompanied by hypertrophy of the left cardiac ventricle, premature and severe generalized arteriosclerosis, development of renal changes with albuminuria and cylindruria and gradual retention of nitrogenous metabolites. Most of the cases observed went on to a comparatively rapid death, and the tumor of the adrenal or some other part of the pheochrome tissue was unexpectedly found at autopsy. There are some forty odd cases on record at present which bear out the relationship of pheochrome tumors to the syndrome of paroxysmal hypertension. In recent years moreover, the diagnosis of this condition was made in several instances during the life of the patient, and three of these cases, all in this country, have been operated on successfully by Mayo, Shipley and Porter. Surgical removal of the tumor brought about disappearance of hypertension and prevented further damage to the heart, arteries and kidneys.

It is logical to assume that large palpable tumors of the pheochrome tissue are not the only cause capable of producing an excess of adrenalin and an increase in blood pressure, followed by pathological changes of the blood vessels. The same might be expected in diffuse hyperplasia of the pheochrome tissue or even in the absence of demonstrable anatomical changes. The role of hyperadrenalinemia, as a possible cause for hypertension, has been considered for a long time, yet in spite of all the evidence produced in its favor this conception was not generally accepted, mainly for one reason: The methods worked out by the physiologist to demonstrate adrenalin even in extreme dilution failed to show a measurable increase of this substance in the blood of patients suffering from hypertension. In view of this failure hyperadrenalinemia was eliminated as a possible factor in hypertension, although it would have been wise to consider the possibility that the physiological methods used were perhaps inadequate or that adrenalin may circulate in the blood in a form or combination which is not amenable to detection by the ordinary methods. Recently, I have tried to call attention to the various fallacies involved in this attitude and attempted to stress the evidence, speaking in favor of adrenal hyperfunction as one of the main factors in the pathogenesis of hypertension. I described changes of the adrenal glands met with in hypertension which are so characteristic that their presence suffices to make the diagnosis of hypertension and arteriosclerosis

by mere microscopical examination of the adrenal glands. In my studies made on several thousand adrenals, I do not recall a single case in which these criteria have misled me. One of the most important among these is the muscular hypertrophy of the wall of the adrenal veins. These veins are provided for with a peculiar apparatus of smooth muscle bundles the contraction of which blocks the lumen and diverts the flow of blood from the main draining vessel to the collaterals. The latter connect the adrenal circulation with the diaphragm and kidney on the left side and the liver on the right side. In hypertension a tremendous hypertrophy of these muscles is found indicating excessive function, suggestive of an attempt to divert the discharged adrenalin from its ordinary course. Such diversion is likely to result in inactivation of the adrenalin before it reaches the heart and arterial circulation. These observations which I have published with Dr. Sherman a few years ago, have since been corroborated by Allen from the Mayo clinic. Another important fact, suggestive of adrenal hyperfunction in hypertension is the increase in the adrenalin load of the glands demonstrable by simple chemical methods. Determinations on 1,000 cases which I published more than twenty years ago, showed that adrenals from hypertensive cases contain 50 to 100% more adrenalin than those of persons with normal blood pressure. Quite recently I also described the frequent occurrence of microscopical nodules in the adrenal medulla in cases of hypertension which are well comparable to, altho much smaller, than the pheochrome tumors observed in paroxysmal hypertension.

Hyperfunction of the adrenal medulla is likely to produce also other symptoms besides hypertension. In recalling the physiological effects of adrenalin you will remember that adrenalin is the chief factor in the mobilization of sugar from its depots, thus producing hyperglycemia and glycosuria. Moreover, it acts as a stimulant upon the whole sympathetic nervous system and upon all the glands which are under sympathetic control. Adrenal medullary hyperfunction, therefore, has to be looked upon as one of the causes in general sympaticotonia, vasomotor disturbances, diabetes mellitus and so-called hyperthyroidism. I do not hesitate, particularly to maintain that a good many of the cases, habitually classified as hyperthyroidism are due to hyperactivity of the adrenal medulla or to relative insufficiency of the antagonist, the adrenal cortex. This applies especially to those cases in which definite enlargement of the thyroid gland is not demonstrable. In diabetes mellitus the prevalent conception considers only the pancreatic pathogenesis, yet anatomical studies have failed to confirm the consistency of the changes in the pancreatic islands, nor do these changes, if present, always impress us as sufficiently severe to account

for the disturbance in metabolism. An attempt to discuss here the pathogenesis of diabetes would lead us too far. Let me draw your attention only to the frequent coincidence of hypertension with diabetes and to the fact that the blood sugar level in hypertension is with very few exceptions noticeably higher than that of the average person of the same age. Without stressing the point too much I would like to say that an excessive function of the pheochromic tissue and subsequent increased sympathetic tonus is one of the factors which are capable of disturbing the normal utilization and storage of carbohydrates.

Hyperfunction of the adrenal cortex is a much more involved problem, at least for the time being. The first information pointing to the possibility of such a condition was obtained by observations made in cases of adrenal cortical tumors. These tumors are accompanied by a variety of symptoms, the manifold appearance of which brought about a good deal of confusion. The diversity of these symptoms was understood only when the age of the patient at the time of the development of the tumor was taken into consideration. If cortical tumors develop in the adult there is a change in the sexual character of the patient. In females, where these tumors are by far more frequent, they bring out masculine tendencies, such as development of hair in the face and all over the body, deep male voice and changes in the external genitalia, particularly enlargement of the clitoris. Malignant tumors are sometimes accompanied by loss of weight but more commonly by a deposit of fat which leads to excessive obesity. This is a constant feature of the benign cortical tumors. In males only a few cases have been observed in which feminization was suggested by loss of hair in the face and over the body, atrophy of external genitalia, obesity of female type and increase in size of the breast gland.

Cortical tumors may develop also in early childhood. Their first symptom is premature sexual development with growth of pubic hair and enlargement of the genital organs. Obesity is present as a rule. Finally congenital cortical tumors have been observed which were accompanied by hermaphrodite development of the genitalia. Thus cortical hyperfunction, if congenital, seems to express itself in hermaphroditism. It leads to precocious sex development in childhood and to an inversion of sex characters in the adult. It is worth while to mention that this adrenogenital syndrome occurs only in tumors of the adrenal glands and is never observed in the so called hypernephroma of the kidney. The latter, according to most textbooks, is derived from aberrant cortical tissue misplaced in the kidney capsule. This belief has been contradicted already on the basis of purely morphological evidence by Stueck and a few other

prominent pathologists. It appears to be definitely shattered by the difference in the biological effects of real cortical tumors and renal "hypernephromas."

The following case, observed sometime ago, beautifully illustrated that obesity is not merely concomitant to the adrenogenital syndrome but actually due to cortical hyperfunction.

A young woman, 23 years old developed extreme obesity. Her weight reached 335 pounds although dieting and liberal administration of thyroid medication were resorted to. Distribution of fat was fairly equal over the trunk, but her legs and forearms seemed to be comparatively slender. Another noticeable symptom was the growth of hair on face and body with masculine distribution of pubic hair. Her voice was deep. Amenorrhea was concomitant. A diagnosis of cortical hyperfunction was made due to either benign cortical tumor or bilateral hyperplasia. Dr. H. Koster explored upon my advice both adrenals. He confirmed the diagnosis of bilateral hyperplasia by inspection and removed the left adrenal, which was several times the size of a normal gland. The result of the operation was startling. The patient sustained a gradual loss of weight, which reached in eight months the figure of 145 pounds, so that at the last time I saw the patient her weight was only 190. This was achieved without dieting or any kind of medication. Her menstruation returned and she seems to be perfectly normal with the exception of her hirsute condition which did not change. This case which we reported but recently, seems to prove three points. First—that diffuse bilateral hyperplasia of the adrenal cortex produces similar symptoms as cortical tumors. Second—these symptoms are amenable to surgical treatment. Third—adrenal cortical hyperfunction must be considered as one of the endocrine causes of obesity.

The recent advances in physiology and pathology of the adrenals have favorably reflected upon the field of therapy. Thus therapy of adrenal disease is giving so much more promise than it was thought possible but a few years ago. We shall divide our therapeutic considerations in two parts, according to the use of either medical or surgical methods. The former are preferably resorted to in hypoactivity or insufficiency of the adrenals, while the latter find their place in the treatment of pathological hyperactivity.

The effectiveness of orally administered adrenal gland is at least questionable although some French authors report beneficial results of their treatment in the milder forms of chronic adrenal insufficiency. Better results are to be expected from the use of isolated hormones.

The use of adrenalin in medullary insufficiency, although advocated for a very long time, was limited partly by its toxicity and partly by its ephemeral effect. The introduction of epinephrine

as a substitute seemed to broaden the possibilities of therapeutic usefulness in view of both its lesser toxicity and its more lasting effect. A new drug, brought out recently in Germany, and marketed under the name of "Sympathol," is said to have quite a prolonged effect and to lack the toxicity of adrenalin. A few recent papers claim that Sympathol is effective also if given orally in contradistinction to adrenalin and ephedrine. Any one of these drugs, if administered timely and in sufficient quantity, might prove useful in combating acute medullary insufficiency. In chronic cases, however, the sympathetic tonus must be braced up also by other remedies, such as thyroïdin, strychnine, nicotine and high protein diet.

In cortical insufficiency administration of the cortical hormone appears to be the logical procedure. I found interrenin useful in case of acute cortical insufficiency. The first case of this kind properly diagnosed and successfully treated with interrenin has been published by myself and Dr. Greenwald four years ago. At present I am using interrenin quite extensively in cases of hyperthyroidism with striking effect. The patients thus treated gain weight, become much calmer and less apprehensive, their pulse rate and blood pressure quiet down and their metabolic rate recedes. I have not seen, however, any definite effect upon the thyroid gland itself, particularly in case of marked enlargement.

The value of the cortical hormone in Addison's disease has been shown by Rowntree and his co-workers from the Mayo clinic and a number of recent papers emphasized its value in case of adynamia. I firmly believe that interrenin will also prove of great value in acute infectious conditions inasmuch as it improves oxidation in the tissues, relieves anoxemia and strengthens the resistance of the organism against invading bacteria and toxic substances. It is to be hoped that further research on more extensive material than I have at my command will soon definitely establish the value of the cortical hormone in these and other conditions.

Hyperfunction of the medullary tissue is not amenable to effective medical treatment. In

pheochromic tumors surgery is the only remedy and an exploratory operation would seem to be justified in every case of paroxysmal hypertension. In the absence of such tumors, adrenalectomy has been resorted to by a few courageous surgeons. Their results were unsatisfactory, as could be expected. Two years ago Dr. Crile presented his experiences in this line, at a meeting of the New York State Medical Society in Rochester. In discussing his paper, I called attention to the fact that by adrenalectomy, not only the guilty overactive medulla, but also the cortex, its antagonist, is removed. Thus no really beneficial results can be obtained. The operation of choice seems to be the denervation of the adrenal gland either unilateral or bilateral. Severing of the numerous nerves which connect the adrenal medulla with the abdominal sympathicus invariably results in atrophy of the medullary tissue. The cortex remains unimpaired, as its function does not depend upon sympathetic stimulation. The operation leaves the main vein and the three arteries intact and otherwise completely liberates the gland from the surrounding tissue. At the meeting in Rochester I quoted two cases of so-called hyperthyroidism, both unimproved after thyroid surgery, which were operated on in the method described by Dr. H. Koster in Brooklyn. Both cases showed remarkable improvement with a return of blood pressure, pulse rate and basal metabolism to normal figures. Dr. Crile just recently reported on a series of some 140 cases upon which he has since performed this operation with highly gratifying results. I feel confident that adrenal denervation will be performed in the future in ever-increasing number on cases of hyperthyroidism, hypertension, diabetes mellitus, and other manifestation of pathologically increased sympathetic tonus.

Surgery will also find new activities in cases of cortical hyperfunction, either due to real neoplasms or to hyperplastic conditions. I would like to warn, however, against indiscriminate operation on obese hirsute women because both obesity and hirsutism might be due to other glandular troubles besides adrenal cortical hyperfunction.

THE MODERN CONCEPTIONS OF HAY FEVER

By H. I. SHAHON, M.D., NEW YORK, N. Y.

From the Department of Medicine, Division of Applied Immunology, New York Post-Graduate Medical School and Hospital, Columbia University, New York City.

HAY-FEVER is a seasonal state of allergy, occurring in individuals hypersensitive to the proteins of various pollens, with clinical manifestations usually limited to the mucous

membranes of the eyes and respiratory tract.

There are three distinct hay-fever types:

(1) The Spring Type (April 15-June 15) which is caused by the pollen from such trees as:

White Ash
Beech
White Birch
Elm
Shelbark Hickory
Sugar Maple
Red Oak
Black Walnut

This hay-fever season does not last so long for each patient as those suffering from the summer and fall types, and they are usually not sensitive to more than one or two of these pollens. All of the trees do not pollinate at the same time, but over a rather long stretch of time, and this is what makes the season seem so long—when you mention the months of pollination.

(2) The summer type (May 15-July 15). This is caused mainly by the pollen of grasses such as:

Timothy
June Grass
Orchard Grass
Bermuda Grass
Sweet Vernal
Rye
Plantain—a weed

Timothy and plantain are the most important plants during this season. They are more common in regions where hay-fever is found. This early hay-fever season is longer than the spring type. The symptoms of these patients are not so severe. In many instances they respond better to the treatment than the late or autumnal type.

(3) The fall type (August 15-frost). This type of hay-fever, also called the late hay-fever, is caused by the pollen from the low ragweed and high ragweed. These weeds grow in most areas of the United States in great abundance. The majority of hay-fever patients are massed in this group. If you claim that "Misery loves company," then these people certainly have company.

Contrary to the general opinion, the pollen of goldenrod is not a frequent offender. Its pollen is toxic to susceptible individuals, but probably only by direct inhalation. Its pollen granules are relatively few in number and viscid, and insect fertilization is common, as is true of some other conspicuous members of this group, such as the daisy and the asters.

The Inheritance Factor: Cooke and Vander Veer,¹ in a study of 504 nonclinic cases of hay-fever and asthma found the family history positive for some form of clinical hypersensitiveness in forty-eight per cent; Spain and Cooke,² in a similar study of nonclinic cases, but with findings in the family history restricted to the presence of hay-fever or asthma, demonstrated a positive family history in 270, or fifty-eight per cent. Adkinson³ and Balyeat⁴ have reported like results. The above studies lead them to believe that "the

sensitization is not directly inherited, although the tendency to spontaneous sensitization is inherited as a dominant character" in the Mendelian sense. Approximately one to two per cent of the inhabitants of any locality, all of whom inhale the pollen, are sensitized. This one fact is essentially positive and conclusive evidence against the theory of a true "pollen toxin" in the Ehrlich sense of the word.

It is generally agreed that in the blood of the spontaneously sensitive individual such as a patient suffering from hay-fever, there are present skin sensitizing "antibodies" or "reagins" which possess the ability to sensitize the skin of the normal individual upon local transfer. However in the hay-fever patient they have not been shown "muscle sensitizing antibodies" in the skin comparable to the "anaphylactic antibodies" as produced in the laboratory animal after antigen stimulation.

Testing and Classification: After a complete history is taken, and a physical examination is made, each patient is tested with extracts of the pollens of timothy, ragweed and plantain irrespective of whether or not the patient gives a history of early hay-fever or late hay-fever or both. In this manner, we detect the possible potential cases of either one, even though there are no positive seasonal symptoms.

Before going into the classifications of these patients, it is of great importance to discuss the methods of testing and the advantages and disadvantages of each method. In the Clinic, at the New York Post-Graduate Hospital, the intracutaneous method is used exclusively.

Skin Tests: Two methods of making skin tests are employed at the present time: the cutaneous or scratch method advocated particularly by Walker,⁵ and the intracutaneous method, advocated by Schloss,⁶ Cooke, Vander Veer, Spain and others. Both have a sphere of usefulness. The intracutaneous, the more delicate method, gives a greater number of positive reactions than the cutaneous, but has the disadvantage of giving a greater number of false positive reactions. This is no handicap, if the results are taken for what they are worth and what they actually indicate and are used only in conjunction with information gained by history, physical examination and special tests. In this manner they are useful and need not lead to serious error. The cutaneous reactions (scratch tests) have their greater sphere of usefulness in testing children (who react better than adults), and of patients sensitive to air carried substances. Scratch tests are also used for testing patients sensitive to agents such as turpentine, benzol, and other substances which might prove irritating or harmful if injected intracutaneously. Cutaneous tests often fail utterly in elderly individuals and in patients whose symptoms occur as a result of a general reaction (as

in food cases). In these, intracutaneous tests often give more marked and convincing reactions. In connection with the testing of drugs and all other toxic substances like rhus-toxicodendron (poison ivy), I might as well mention two other methods of testing, i.e., the ophthalmic test and the Patch test.

Method of Performing the Ophthalmic Test: This test although sensitive, is not necessary for the routine diagnosis. It is employed only in vague and unusual cases, to further confirm the degree of sensitiveness. A little of the 0.001 solution of pollen extract is dropped in the eye, and, if positive, will cause reddening and itching of the caruncle and conjunctiva, with irritation of the nose on that side, and sneezing. The reaction should be terminated by a drop of epinephrine. It requires a stronger solution to elicit a reaction in the eye than in the skin.

There are men that use the pure pollen in performing this test, that is, they place a little in the eye instead of the solution. The writer feels that it is not such a good procedure because the pollen is too potent and may act as a foreign substance.

Method of Performing the Patch Test: A very small piece of blotting paper is saturated with the substance to be tested, which is usually in solution form. This is applied over the volar aspect of the forearm and covered with a piece of adhesive plaster. After an interval of twenty-four hours, this area is examined for any reaction that may develop, and it is read as marked, moderate, slight or negative, according to the amount of erythema and the size of the wheal produced. In some instances the reaction is delayed and the site should be examined again two or three days later.

The writer feels that both the cutaneous and the intracutaneous methods are useful and neither should be used to the exclusion of the other.

It is very important to remember this: skin tests in the hands of physicians unacquainted with their interpretation usually lead them to gross error. For them, common sense, clinical tests and history are much more dependable.

Method of Performing the Cutaneous Tests: The foreign materials in dry powdered form are applied to the scarified areas on the skin, and to this is added a drop of tenth normal sodium hydroxide solution. The appearance of a hive (wheal), within 20 to 30 minutes, with pseudopods surrounded by an irregular area of erythema indicates a positive reaction. Button reactions (hives) without pseudopods are called negative.

Method of Performing the Intracutaneous Tests: Cooke,⁷ Spain and Vander Veer⁸ advocated the use of standardized solutions in varying strengths and injected intracutaneously 0.01 cc. The appearance at the site of the test within 10 minutes of a hive with pseudopods and erythema indicates a positive reaction. A reaction is slight

or moderate or marked depending upon the size and outline of the wheal and the amount of erythema.

A *negative reaction* is one which shows no increase in size of the original wheal with slight or no erythema.

A *slight reaction* is one which shows a slight increase in the size of the original wheal with moderate erythema.

A *moderate reaction* is one which shows an increase in size of the original wheal two or three times, with a definite area of erythema.

(These reactions are all round wheals with no irregularity.)

A *marked reaction* is one which shows a large wheal, irregular in outline, with pseudopods, and an area of erythema of varying size.

A *marked plus reaction* is at least one and one-half inches in diameter with the characteristics of a marked reaction.

The intracutaneous method is very useful especially in patients whose skin does not respond readily to cutaneous tests. This method necessitates the making of stock solutions at yearly intervals, or oftener, and the repeated making of serial dilutions, some several hundred in number.

In the Clinic the following method is used and the reactions are read at the end of ten minutes. The tests are made on the outer surface of the arm with the usual sterile precautions. Approximately one one-hundredth cubic centimeter of the 0.0001 and 0.001 dilutions are injected intracutaneously, and after ten minutes, a similar amount of the 0.01 dilution is injected, if the previous tests are negative or only mildly positive. No blood should ever follow the withdrawal of the needle, and there should be a raised, dead-white wheal a quarter of an inch in diameter. To get a satisfactory wheal, it is advisable to grip the arm at the site of the injection very firmly and exert considerable tension on the skin, when the insertion of the needle is not felt at all and even a small child will remain quiescent. The reactions are read negative, slight, moderate, marked and marked plus, depending on the size of the wheal and the irregularity, and the amount of erythema surrounding it. Itching of the site is usually a frequent early sign of a positive reaction. If negative to 0.01 dilution, a test with 0.05 dilution is tried on the following clinic day, but is usually unnecessary to test with any stronger dilution than this, as reactions to this are often marked and difficult to control. Patients failing to give a reaction to this strength cannot be considered to be ragweed, timothy, or plantain sensitive, providing they have no definite positive clinical symptoms.

Patients are then classified according to Vander Veer, Cooke and Spain⁹ (Table I), as to the degree of the reactions of the various dilutions of the extracts into classes, AA, A, B or C.

TABLE 1 (Slightly Modified)

AA	A	B	C
0.00001 = marked	0.0001 = marked	0.0001 = moderate	0.0001 = slight
0.0001 = marked plus	0.001 = marked plus	0.001 = marked	0.001 = moderate
		0.01 = marked plus	0.01 = marked

Classes AA and A are very sensitive; B and C are less sensitive. Since the degree of the skin sensitivity is not always an indication of the degree of general sensitivity, the above classification cannot be followed blindly; but variations are necessary in individual cases depending upon their response to treatment from week to week. Just as much care must be exercised in the treatment of B and C cases as of the A cases. When in doubt as to the right classification it is always best to treat a Class C as B, a Class B as A, and a Class A as AA, for the first year at least. In doing so, marked local and constitutional reactions are avoided. There were 426 cases treated at the Clinic from March to October 2nd, 1931, by this method with constitutional reactions occurring in only a small percentage as discussed later.

Prophylactic Treatment: Having determined the class of sensitivity of the patient, the initial dose and the subsequent doses for each class are outlined in the table below.

TABLE 2

Prophylactic Treatment, Average Dosage for Various Classes		Various Classes			
		AA	A	B	C
		0.00001 marked 0.0001 marked plus	0.0001 marked 0.001 marked plus	0.001 marked 0.01 marked plus	0.001 mod. 0.01 marked

*This dose continued at four to seven-day intervals during the season.

The prophylactic treatment of the hay-fever should begin at least three months before the on-

set of the season. Injections in the Clinic are given every seven days and, in this vicinity, are so regulated that serial increases are given before the onset of the season; the top dose thus reached should be continued weekly throughout the season. If the top dose of the class is reached early and is well tolerated by the patient, higher doses should be given up to the beginning of the season. Care should be taken to question the patient at each time before receiving the treatments as to any general symptoms. If a marked local reaction is produced with some sneezing, coryza, etc., repeat the dose at the time of the next injection or revert to the preceding dose.

The aim in any hay-fever season should be the attainment of the highest possible dosage with safety.

In 1931 the patients who received the highest possible dose throughout the hay-fever season responded much better to the treatment. Many class C patients reached the 0.1 dose, while others reached 0.05 only, but the average was kept down, because of the delay in starting the treatment.

One should bear in mind, though, there is no definite rule to follow in treating these hay-fever patients. Each dose is a law unto itself.

If treatments are missed for a period of two weeks or over, the dose should be reduced. For instance, if the patient's last dose was .01, give 0.004 as the dose.

The Results of the Treatment: There is no doubt the patients that start the treatment early and receive regularly the respective dose, get a great deal of benefit. No one but a sufferer can truly appreciate what this really means.

Due to the unusually excessive amount of pollen in the air last season the results were less successful than the average year. The very hot summer we had, was the cause of this excessive pollination.

Studies of the results of treatment of hay-fever at the Clinic,¹⁰ during previous years show the following results:

In 1929 out of 104 cases of hay-fever studied at the Clinic, 80 patients could be considered successfully treated. Of the unsuccessful cases, one reported sixteen severe days, but was 50 per cent improved the year before; another had ten severe days, but the top dose was only 0.006, because of two constitutional reactions; others had insufficient treatment. These reports were checked up by the patient's own expression of results in percentage at the end of the season and the figures are as follows:

38 per cent reported 80 to 100 per cent improvement.

50 per cent reported 50 to 80 per cent improvement.

12 per cent reported an improvement of less than 50 per cent.

A number of points of importance are worth mentioning, though, in connection with the results of treatment.

(1) In general, cases of ragweed hay-fever are more resistant than those of the vernal or early type.

(2) Patients showing the highest grade of sensitization give the most satisfactory therapeutic results and seem to require less treatments to control their symptoms.

(3) In any case better results may be confidently expected with each successive year.

(4) The question as to permanent cure is, of course, a pertinent one. Probably the so-called immunity which is manifested by the clinical alleviation or absence of symptoms, is slowly lost during the winter, the patient gradually returning to the sensitive state. This point, however, is not settled. There are undoubted instances of spontaneous cure. So far no permanent desensitization has been obtained, but each year's treatment has effected a definite and permanent lowering of the patient's original reactivity.

(5) In cases of hay-fever complicated by asthma, the results are not so encouraging especially where not only pollen, but other excitants must be considered. These patients should be given great consideration and their asthma should also be treated. They should receive medicinal treatment as well, namely, ephedrine sulphate and iodides internally. They should also be tested for other possible offending substances namely, the inhalants, the protein foods, the vegetables and the fruits. All nose and throat infections should receive symptomatic treatment, deferring any operative measures until the end of the season.

Constitutional Reaction: This condition is still a puzzle to the allergist. The exact cause is not yet known. It develops in the more sensitive hay-fever patient as well as in the less sensitive one. It is found to occur in class A patients as well as in class C patients. It may be a slight reaction or a very severe one. This many times keeps the allergist in great moments of anxiety. In certain cases the reaction is so severe that it takes all the good out of the practitioner's zeal to undertake this form of treatment. Few fatalities have been on record following this form of treatment, although the symptoms are often times alarming.

The causes of this constitutional reaction have been divided into four groups according to Vander Veer, Cooke and Spain.⁹

(1) Too rapid increase of the dose.

(2) Injection directly into the vein.

(3) The substitution of a fresh extract for an old during the course of the injections.

(4) Too brief an interval between doses.

The constitutional reaction following the too-rapid increase of the dose, could be avoided often times by carefully questioning every patient as to the amount of local and the late constitutional reaction if any. Every constitutional reaction should be followed by the same or a diminished dose, never by an increased dose.

The injection into a vein is a thing which no one can definitely avoid. With all due care, this sometimes happens. It is a good policy to withdraw the plunger from the syringe each time before that injection is given. If blood enters the syringe then withdraw the needle and inject into some other place. This type of reaction comes immediately, and the doctor should be on the guard to give adrenaline at once.

Regarding the substitution of a fresh extract for an old one, the writer feels that this is sometimes responsible for the constitutional reaction which follows such procedure. It is always best when getting a fresh extract to give a smaller dose than the previous one. For instance, if the dose of the old extract was 5/10 of a c.c., the dose of the new extract should be 3/10 of a c.c., or smaller.

Regarding the too brief an interval between doses, it is evident, of course, like any other form of treatment, that there is the danger of a cumulative effect following such procedure. It has been the experience of the allergists that with all due care, reactions occur even though the dose has been properly estimated before giving it. It has been shown by Levine and Coca¹¹ that an interval of seven days is necessary for the complete elimination from the system of the pollen administered by injection.

With all the soundness of the above reasons, the writer feels that there must be other causes which we have not been able to perceive yet with the present method of treatment.

What Is a Constitutional Reaction? It is a reaction following the injection of a foreign substance in this case being a pollen absorbed too rapidly in the circulation of hypersensitive individuals. It usually begins with a dry, hacking cough, frequently repeated cough, together with a rapidly increasing size of wheal at the site of the injection. The latter does not always happen, of course. There may be an itching of the palm, ear or soft palate, an early congestion of the face followed by a pallor, congestion of the eyes, wheezing, and rapid, difficult respiration similar to that of an attack of asthma. At the height of the reaction, syncope may develop. The pulse is fast and small, the breathing heavy and noisy, and the appearance of the patient may become alarming. At times the local reaction spreads to involve the

entire arm, and often the sites of the previous injections on either arm light up with wheals. There may be intense itching, followed by an outbreak of urticaria involving the entire body.

What to Do with These Cases? The first reasonable thought is to inject $\frac{1}{2}$ c.c. of adrenaline solution 1-1000 subcutaneously in the arm and then place a tourniquet above the site of the prophylactic dose. The adrenaline should be given as soon as the first sign of the hacking cough is observed on the patient. In most of the cases the patient himself calls this symptom and others to the attention of the doctor in the Clinic and asks for adrenaline if he has had experience with a previous reaction.

Unless improvement is obtained within five minutes a second injection of adrenaline is given. In severe cases the adrenaline may be administered intravenously. As a rule most of the cases get immediate relief following the administration of adrenaline subcutaneously.

The experience of the writer has been that when constitutional did occur, the patient had reached or approached the top dose for the Class to which he belongs. If a constitutional reaction recurs when the dose of the first reaction is reached, the top dose for that patient should be considered to be about $\frac{2}{3}$ the potency of the dose causing repeated constitutional reactions. At times it is possible to go beyond the dose of a previous constitutional reaction, especially when due to an intravenous injection or to a too rapid increase of the dose.

The rate of a constitutional reaction as a rule is not high if all the precautionary measures are taken. In the Clinic it is found to be around 10 per cent in all patients treated or in less than 1 per cent of all injections. In private practice it is also about the same.

The Perennial Treatment of Hay-Fever: This type of treatment is not employed at present at the Clinic, but several men are adopting it now because they feel that certain patients do better under this method of treatment. In 1920, Cooke, Vander Veer and Spain⁸ advocated this method. They selected ten to twelve patients with hay-fever, who had done well under the seasonal treatment, and instead of stopping their injections at the end of the season, the maximum dose was repeated at intervals of three or four weeks during the winter. The results were in the main satisfactory. In 1925, with the introduction of Coca's solution for the extraction of pollen they again resumed the monthly treatments. This time they selected 70 cases, and the results were distinctly encouraging. All of these patients were treated in their office and carefully observed.

The method of treatment is very simple. In-

stead of discontinuing at the end of the season, the patient is instructed to return once a month throughout the year, and each time receives the maximum dose attained during the season.

During the season it may be necessary to give injections oftener than once a month, and the interval between them is determined by clinical symptoms. The average total dose is larger under the monthly system, being 0.13 mg. nitrogen at the beginning and in mid-season as compared with 0.07 and 0.09 mg. nitrogen in the same cases during the previous season under weekly injections.

Summary: My contention is that there are many problems yet to be solved in connection with the subject of protein sensitization in general. The present method of treatment of hay-fever is generally satisfactorily successful. Despite the incompleteness of our knowledge, we need not condemn the victim of hay-fever to six weeks of untold misery—in many times to the entire summer season. Each sufferer of hay-fever should receive the prophylactic treatment nevertheless with the object of minimizing the distressing symptoms caused by this malady. In addition to this, the patient's general health should be carefully watched, and any infection of the nose and throat and the sinuses should receive adequate treatment. Last by no means the least, to my mind, the best method of prophylactic treatment is to exterminate all the ragweeds. This seems a very great problem, but by the enactment and enforcement of laws in each state much could be accomplished to alleviate or rather eliminate this dreadful disease. No one knows the value of good health until he has lost it or has been the victim of hay-fever or some other form of malady.

SOME DRIED FOODS USED IN INFANT FEEDING

By CHARLES W. MARTIN, M.D., FAR ROCKAWAY, N. Y.

From the Department of Pediatrics, New York Post-Graduate Hospital and Medical School. Read before the Brooklyn Pediatric Society, Brooklyn, N. Y.

THE use of dried foods is a subject that is becoming more and more an important factor in infant feeding, because of the great scientific strides made in the preparation of the dried foods, and also because of the degree to which cow's milk has been modified so that it more closely resembles the best infant food, breast milk, besides combining in some cases, with this modification, the addition of one or more of the extremely important vitamins. I realize that the dry foods are so numerous that it would be an impossible task to present the subject in full, so that I am going to present only some of these foods, which it has been my privilege to give a fair clinical trial either at the N. Y. Post-Graduate Pediatric Clinic or in my own practice.

Methods of Drying Milk—There are at present two methods of drying milk; the first and the older of the two, the Just-Hatmaker roller dry method in which milk is passed over the surface of a hot roller in the absence of oxygen, thereby evaporating the water in the milk but preventing the deterioration of the sensitive vitamins A, C and D as conclusively proven by Hess,¹ Cavanaugh² and numerous other workers, who have shown that the vitamins are not destroyed in the absence of oxidation. After the water is evaporated the milk is scraped from the roller as a flaky, dry powder which is quite readily soluble in water. During this process there is a partial coagulation of the protein and a failure to break up the large fat globules, which, however, does not render the protein less valuable nutritionally nor seem to interfere with the digestibility of the fat.

The other method, which is now more extensively employed, is the Merrell-Gere spray process. In this method the milk is forced as a fine spray into an oxygen free chamber through which currents of warm air are passed, thereby evaporating the water and throwing the solid portions of the milk to the bottom of the chambers as a dry powder. During this process the protein is not even partially coagulated and when redissolved is present as a fine flocculent precipitate; the large fat globules are broken up and are, therefore, more readily assimilated and metabolized than in their raw state. There is no change in the vitamin elements due to the absence of oxidation.

Effects of Drying Milk—Let us see if there are any advantages or disadvantages in the use of dried foods.

It has been definitely proven that the sugars are not changed in the drying of foods, therefore,

they are as readily digestible as in the raw product.

Secondly, the fat is rendered more easily digestible because the globules are more finely broken up; and, furthermore, it has been found that there is no chemical or nutritional change in the fat during the drying process, therefore the fat is more readily handled by the infant if given in the dry state than in the raw state.

Thirdly, the protein seems to be more readily digestible if dried, because it has been found that the casein albumin is broken up during the drying process so that in the stomach it is precipitated as a fine flocculent curd similar to the lacto-albumin curd, instead of the large tough curd as is the case with raw unmodified cow's milk casein. Chemically and nutritionally there is no evidence of any change in the protein element during drying; therefore, there would seem to be an advantage in favor of feeding dried foods from the protein standpoint.

The calcium, potassium and phosphorous salts are rendered less soluble by the drying process, but inasmuch as there is an excess of from one to three times in these salts over breast milk, this would seem to be an advantage rather than a disadvantage. There is no evidence that the nutrition is impaired because of this lack of solubility.

From the vitamin standpoint, we know that there may be insufficient vitamin A, B, C, D, E and G, especially B, C and D vitamins, in either breast milk or cow's milk. It has been conclusively proven that there is no loss of vitamin during the drying process; but because of the insufficiency in these factors, it is necessary that we overcome this by supplying more of these in the use of dried, raw, or even breast milk.

Bacterial Content—Aside from the advantages in regard to the digestibility and assimilability of the elements in the dried state over that in the raw, there are other more important advantages in that dried milk products are made from milk which is produced and handled under supervision, which renders it to all intents and purposes up to the standards of certified milk; furthermore, it is sterilized during the process so that the bacterial count is reduced to a minimum and all pathogenic and other bacteria are destroyed except certain of the spore-bearing and certain other non-pathogenic organisms. In an analysis of one of the products used in our experiment by Dr. J. M. Sherman,³ Professor of Bacteriology, Cornell University, there were 16,200 bacteria per c.c. of the reconstructed milk, none of which were pathogenic for humans.

Another advantage of dried foods is that they

keep well because of the low bacterial count, and because they are hermetically sealed in the presence of carbon dioxide which prevents oxidation.

Advantages—Other advantages of dried milk are the simplicity of preparing; freedom from climatic influences, spoiling in warm weather or freezing in cold weather; also they seem to be more readily handled where there is either a partial or marked allergy to milk as such; and they lend themselves more readily than raw milk to concentrated feedings, which are becoming more and more favored in infant feeding. A further advantage is that in some of these foods sufficient vitamin is added to prevent rickets, tetany and scurvy, and we believe in time vitamin B and E will be included as well, thereby putting us another step forward in preventive medicine.

It would seem, therefore, that there are distinct advantages in the feeding of dried foods, and so let us now turn to an analysis of some of these products we have used. Allow me also to state that at our clinic we have a great percentage of so-called difficult feeding cases and our clientele comes chiefly from the poorer and least intelligent sections of the city, and, therefore, our results must be viewed accordingly.

S. M. A.—First, let us consider the dried milk known by the trade name "S. M. A.," put out by the S. M. A. Corporation, Cleveland, Ohio, by permission of the Babies and Children's Hospital of Cleveland, through the courtesy of its originator, Dr. H. J. Gerstenberger. The theories upon which S. M. A. were created, and the marked successes which have been obtained by its use, justify its careful survey. S. M. A. is described by the Committee on Foods of the American Medical Association as follows:

"S. M. A. is a food for infants—derived from tuberculin tested cows' milk, the fat of which is replaced by animal and vegetable fats including biologically tested cod liver oil; with the addition of milk sugar, potassium chloride and salts; altogether forming an anti-rachitic food. When diluted according to directions, it is essentially similar to human milk in percentages of protein, fat, carbohydrates and ash, in chemical constants of the fat and in physical properties."

It has been shown by Langstein,⁴ Edelstein,⁴ Osborn,⁵ Mendel,⁵ etc., that lacto-albumin contains a higher amino acid content, which is essential to growth, than has casein. It is known that cow's milk contains approximately four-fifths casein and one-fifth lacto-albumin, therefore, there is a deficiency in amino acids, when compared with breast milk containing approximately one-half lactoalbumin and one-half casein. In S. M. A. a part of the casein is removed and additional lactoalbumin added, and the proportion of protein in the food is reduced to that of breast milk, 1.3 to 1.5, thereby enhancing normal gastric, duodenal and intestinal di-

gestion, as an excess of protein causes the hydrochloric acid to unite with it, and it is not, therefore, free to act as an activator of secretion and as an anti-bacterial agent.⁶ Proper amount of protein is necessary also to allow rather than to inhibit normal fermentative bacterial flora in the intestinal tract. In order also to obtain this normal intestinal flora sufficient and the proper kind of carbohydrate must be present. As we know cow's milk is low in carbohydrate and in S. M. A., this is corrected by the addition of lactose. Lactose is used because as shown by Sittler,⁷ the normal intestinal flora is best preserved by this sugar, also because the fats seem to be more readily and completely burned in its flame, and also because it helps to supply sufficient galactose⁸ for the development of the central nervous system. S. M. A. contains 7.3 to 7.5 lactose, whereas, the average sugar content of breast milk, according to the late Dr. L. E. Holt,⁹ was 7.57.

Fat—The largest modification in S. M. A., however, is in the fat content and in the character of fat used. Proper quantity of fat is necessary, according to McCollum,¹⁰ Holt,¹¹ Czerny,¹² Gerstenberger¹³ and Marriott⁶ to supply vitamin A and D; to allow for growth; to enhance calcium absorption; to promote immunity; save nitrogenous waste and allow proper nerve and bone growth. Proper quantity and kind, if we are to follow nature, is that found in breast milk. S. M. A. fat is present in the percentage of 3.5 to 3.6 and is composed of cocoa butter, coconut oil, cod liver oil, beef fats, which gives the same saponification number, same iodine number, same Polenske number, same melting point and same Reichert-Meissl number. (This is very important, as it has been shown,^{14, 15, 16} that the difficulty in handling the fat in cow's milk is chiefly due to the difference in volatile fatty acid content which is measured in this way. Breast milk contains 1.6% volatile fatty acids, whereas cow's milk contains 10%. Also the fat of S. M. A. is anti-rachitic and antispasmodic because of its 10% cod liver oil content.

Minerals—The mineral salts are also modified in quantity, character and relation one to the other in S. M. A., which has been shown by Freidenthal¹⁷ and McCollum¹⁸ to be very important for proper bone, cell and nerve growth as well as for proper secretion, absorption and excretion. The salt content of S. M. A. is .25 to .30 contrasted with breast milk, .215 to .226.

Vitamins—Vitamin A and D is supplied in sufficient amount in S. M. A. to prevent rickets and spasmodophilia. Vitamin B must be supplied by added cereal; and vitamin C must be supplied with orange juice except in Protein S. M. A., which has sufficient—20 c.c. of lemon juice to the quart—to be antiscorbutic.

FIGURE 1

Comparative analysis of Breast Milk, S. M. A. and Protein S. M. A. when diluted properly.

Protein S. M. A. is similar, elementally and chemically, to plain S. M. A., but is modified to simulate both protein and lactic acid milk by being changed percentage and physically. Protein S. M. A. has a protein content of 3.5 (higher than protein milk and lower than acid milk), fat 2.2, lactose 2.8 (higher than protein and lower than acid milk), salt .6, Ph. 4.6. (See figure 1.)

Clinical Results—In our work with S. M. A. 72 cases were started, of which 11 were dropped because they failed to return, 4 were dropped because of nonco-operation and 3 were taken off because of illness, which prevented leaving the cases on over four weeks. This left in our series 54 cases which were carried four weeks or longer. The average period these cases were on the product was twenty weeks. Our findings in this series were as follows:

The average birth weight of babies reported, $7\frac{3}{4}$ lbs.

Average age at which babies were started, $3\frac{3}{4}$ mos.

Average gain per week of babies under 6 mos. (39 babies reported on), $5\frac{3}{4}$ oz.

Average gain per week of babies over 6 mos. (36 babies reported on), 4 oz.

Average gain per week of all babies (54 babies reported on), 5 oz. (See figure 2.)

FIGURE 2

Composite weight chart of Cases on S. M. A.

The conclusions we came to from an analysis of the feeding, development and physical findings on these cases were as follows:

1. S. M. A. is not a panacea.
2. The younger the age of the baby when starting the use of S. M. A. the more satisfactory the results.
3. The stools of S. M. A. resemble more the stools of the breast-fed baby than the bottle-fed baby, in that they are occasionally green and occasionally show fat curds and mucus.
4. Plain S. M. A. or Protein S. M. A. is difficult to feed to the child with anorexia and is surely not a cure for anorexia.
5. There is sufficient cod liver oil present to protect against rickets. Six of our cases showed craniotabes without other signs of rickets and when x-rayed no rachitic changes were noted.
6. It can be fed to the sick child in higher proportions than other foods without causing a parenteral gastroenteritis.
7. Vomiting and spitting up are no more marked than on other foods.
8. Protein S. M. A. did not check diarrhoeas in the few cases in which it was tried. A fair clinical trial, however, was not made, as the cases were too few in number.

9. The cases which were on Protein S. M. A. showed no evidence of scurvy, therefore, there would seem to be sufficient vitamin C present.

10. Indications for use of S. M. A.

- (a) Well babies, who do not do well on other foods.
- (b) Mild cases of malnutrition.
- (c) Prematures.
- (d) Selected cases of eczema.
- (e) Complemental and supplemental feeding.
- (f) Mild infections with failure to gain.
- (g) Babies deprived of breast milk soon after birth.

Our results with S. M. A. were not as good as reported by Gerstenberger¹⁹ and others; but, I believe, this can be explained by the fact that most of our cases put on S. M. A. were difficult feeding cases with unintelligent mothers, and

many of them—nearly half—had rather severe intercurrent infections during the trial.

Recolac—Recolac, a reconstructed milk, is similar to S. M. A. and in our rather limited number of cases, similar results have been obtained, although there would seem to be more difficulty in the handling of the fat than with S. M. A. Similac, which will be referred to later, also resembles S. M. A. in that it is a reconstructed milk.

Klim—Klim was given a rather extensive trial in our clinic in order to find out if a powdered whole milk could be used in place of fresh cow's milk. Klim, as you know, is made from milk which is produced under the supervision of the New York City Health Department, with the co-operation of the Merrell-Soule Co., so as to insure clean, safe milk. It is then pasteurized and dried by the Merrell-Gere spray process. During the entire process it comes in contact with only sterilized, glass-lined pipes and tanks, and, therefore, the finished product has a very low bacterial count, none of the bacteria being pathogenic. Furthermore, to insure the keeping of the product and this low bacterial count, it is sealed in vacuum cans from which the air is displaced by carbon dioxide. During the process of manufacture the large fat globules are broken up, which renders the fat more readily emulsified on reliquefaction, and, also, renders the fat more readily digestible by the infant. There is no evidence of any change in the chemical or nutritional value of the sugar or salts. There is as much vitamin present as in the raw cow's milk. The protein curds are broken up, so that they are as readily digestible as boiled cow's milk protein, and, furthermore, there is no evidence of any coagulation, chemical or nutritional change in the protein element. (See figure 3.)

Clinical Reports—In our work with Klim 134 cases were put on the product, of which 28 cases were dropped because of nonco-operation, and 6 were dropped because of illness, which prevented us keeping these cases on the product for over four weeks. The average length of time the remaining 100 cases were kept on the food was eighteen weeks.

The average weight at which the cases were started was 9 lbs. 9 oz.

The average age of the babies started under 6 mos. of age was 12 weeks.

The average gain per week of babies under 6 mos. was 634 oz. (79 cases reported on).

The average gain per week of babies over 6 mos. was 434 oz. (53 cases reported on, 32 being cases started under 6 mos. and carried beyond 6 mos. and the remaining 21 cases being put on when over 6 mos. in age).

The average gain per week for all cases (100 cases reported on) was 6 oz. (See figure 4.)

The conclusions we came to from an analysis

FIGURE 3

Comparative analysis of Cow's Milk and Klim, when diluted properly.

of the feeding, development and physical findings were as follows:

1. Klim was taken as well as fresh whole milk.
2. The stools, 1-3 daily, resemble the stools of milk and water feedings, except that they were as a whole less constipated. The fat appeared to be somewhat better digested than on fresh cow's milk and no protein curds or protein indigestion were found in any of the cases.
3. Sleep was normal except in a few hyper-tonic babies.
4. The incidence to rickets and scurvy was no more prevalent on the dried food than on fresh

FIGURE 4

Composite weight chart of cases on Klim.

milk. Egg yolk, cod liver oil and orange juice being used to supply vitamins A, C and D.

5. The growth and development was equally as good as on fresh milk.

6. Indications for the use of Klim:

- (a) In place of cow's milk when desired.
- (b) Constipated cases on boiled milk.
- (c) Impaired digestion on fresh or boiled cow's milk.
- (d) Questionable purity of fresh cow's milk.
- (e) Convenient for cases who are traveling.
- (f) In place of cow's milk where this is frozen.
- (g) Convenient food for complemental or supplemental feedings.

In our work with irradiated Klim, published by De Sanctis, Ashton and Stringfield, the following conclusions were reached:

1. In a series of 10 cases tried on 25% irradiated milk, 5 cases, or 50%, showed definite clinical and x-ray evidence of rickets, therefore, these cases were not protected against rickets.

2. In 30 cases on 100% irradiated milk, 24 were protected against rickets clinically; 5 were protected clinically, but x-ray showed evidence of dietary disturbance in the epiphyses of the bones. These changes, however, were not pathognomonic of rickets and, therefore, can be called doubtfully protected, although, for practical purposes they were rickets free. One case developed rickets and was not protected.

3. Milk to be antirachitic, therefore, must be 100% irradiated.

4. Irradiated milk will undoubtedly in the future play a large part in the solution of the prevention of rickets.

Mead's Powdered Whole Milk—Mead's powdered whole milk is similar to Klim in all respects and in the few cases we have used it, it is just as readily digested.

Dryco—Dryco is dried 2% fat milk, prepared by the Just-Hatmaker process and has an advantage over whole dried milks in babies with a lowered fat tolerance, that is, in babies who vomit diluted whole milk or who show fat curds on higher fat mixtures. Dryco, over a number of years' trial, has been a dried food of marked merit. It is now irradiated and according to Supplee and Dow²⁰ is antirachitic.

Lactogen—Lactogen is also a dried whole milk, but is modified by the addition of lactose before drying so that it more closely resembles breast milk in its carbohydrate content. Also the fat is rendered more readily digestible due to the fact that the milk is homogenized before drying, which process breaks up the fat globules and renders them more easily digested on reliquefaction. The protein is rendered more readily digestible due to the fact that it is dried by the spray process. (See figure 5.)

Lactogen would seem to possess certain very definite advantages to recommend it for infant feeding, but we, personally, cannot recommend it because we have not as yet given it a fair trial clinically.

FIGURE 5

Comparative analysis of Breast Milk, Cow's Milk, Klim, Mead's Powdered Whole Milk, Dryco, Recolac, and Lactogen, when diluted properly.

Similac—Similac is a totally reconstructed milk put out by Moores and Ross under the supervision of A. W. Bosworth. It simulates, as its name, Similac, implies, breast milk. Chief importance in the adaptation of Similac to breast milk is in the salt content and their relation one to the other. That this modification is an important one has been shown experimentally and clinically by Bosworth,²¹ Bowditch²² and others. Through this modification not only proper salt absorption is promoted, but also normal fat and protein digestion, absorption, metabolism and excretion are favored. It is known, as previously stated, that there is nearly three times as much salt in cow's milk as in breast milk, but it is not so much the quantitative difference, but the qualitative difference, especially in the calcium, sodium and potassium salts which interfere with the digestion of cow's milk. Let us analyze the difference in salt content between cow's milk and human milk and let us see how Similac is made to correspond to that of breast milk. (See figure 6.)

FIG. 6—COMPARISON OF SALT ANALYSIS OF COW'S MILK, BREAST MILK AND SIMILAC

	<i>Cow's Milk</i>	<i>Breast Milk</i>	<i>Similac</i>
Calcium combined with Protein054 gm.	.024 gm.	.030 gm.
Mono - Magnesium Phosphates103 gm.	.027 gm.	.027 gm.
Di-Calcium Phosphates175 gm.	.000	.000
Di-Potassium Phosphates230 gm.	.000	.000
Mono - Potassium Phosphates000	.069 gm.	.000
Potassium Citrates052 gm.	.103 gm.	.103 gm.
Sodium Citrates222 gm.	.055 gm.	.055 gm.
Calcium Citrates119 gm.	.059 gm.	.059 gm.
Iron	Trace	Trace	Trace
Sulphur with Protein022 gm.	.001 gm.	.001 gm.
Phosphorus with Protein022 gm.	.001 gm.	.001 gm.
Calcium Present, 1 gram per 100 c.c. in Similac			

As can be seen from the chart, there is not only a marked excess of calcium in cow's milk over that in breast milk, but there is a difference in that the greater part of the calcium is present as insoluble calcium phosphate or calcium caseinate, which are not found in breast milk, and so Similac follows nature by eliminating these forms of calcium. The sodium salts are reduced in Similac from .222 as in cow's milk to .055 and the potassium salts are reduced from .282 to .103, thereby favoring better utilization of the protein and fat present.

The protein in Similac is rendered more digestible than the protein of cow's milk due to the

fact that calcium is removed from the milk; and instead of the casein being precipitated as an insoluble calcium caseinate in the presence of the gastric juices, it is held in true solution in the form of sodium and potassium caseinate. This fluidity, according to Klein,²³ hastens the emptying time of the stomach, and also through the fact that the protein is held in solution, protein and fat digestion is favored in the intestinal tract for reasons previously stated.

Because of the marked physico-chemical difference between cow's milk fat and breast milk fat, the fat of Similac has been modified so that it resembles breast milk fat, especially in its volatile fatty acid content and butyric acid content (B.M. 1.4%, C.M. 5.4%). The fat in Similac is composed of 20% butter fat, 1% cod liver oil, 59% coconut oil and 20% olive oil, which from a physical, chemical and metabolic standpoint is similar to breast milk fat. Furthermore, this fat mixture is homogenized before drying and thus it emulsifies readily on reliquefaction. Lactose is added to make up the carbohydrate deficiency of cow's milk in preference to other sugars because it is the sugar found in breast milk; and, furthermore, it has been shown by Bergeim²⁴ that lactose favored calcium and phosphorus absorption, while the other sugars did not. Mathews⁸ has shown that lactose is essential for proper nerve myelinization since galactose is an essential constituent of the galactolipin making up myelin.

There is no destruction of vitamin during the process of manufacturing Similac and it is more antirachitic and antispasmodic than cow's milk or breast milk because of its 1% cod liver oil content, and because calcium and phosphorus absorption are favored as noted previously, and, also, because of the inter-relation of the salt content giving to the body salts in the proportions as dictated by nature in breast milk. (See figure 7.)

In our work with Similac, we did not use altogether the product now on the market, as we had two types of Similac, one with a calcium lower than the calcium content of breast milk and one with a calcium content the same as breast milk. Ten of our cases were changed from one product to the other and it was found that the average gain per week on the low calcium Similac was 5 3/4 oz., whereas the average gain on the higher calcium formula was 6 1/2 oz. It would, therefore, appear that a calcium level similar to breast milk has a decided advantage. Our figures are compiled on 35 cases, 5 of which were discontinued because of lack of cooperation, 1 because of severe intercurrent infection and 4 were put on other formulae without any stated reason, leaving us 25 working cases. The average time these cases were on Similac was seven-weeks.

The average birth weight was 6 lbs.

FIGURE 7

Comparative analysis of Breast Milk and Similac, when diluted properly.

The average weight at start, 9 lbs.

The average age at start, 3½ mos.

The average gain per week under 6 mos. (15 cases), 6+ oz.

The average gain per week over 6 mos. (10 cases reported on), 5½+ oz.

The average gain per week of all cases (25 in all), 5¾ oz. (See figure 8.)

An analysis of our feeding histories gave us the following results:

1. Babies took Similac as readily as our formulæ of milk, water and dextrimaltose.
2. The sleep was good except in 4 cases where the children were markedly hypertonic.
3. The stools resembled the stools of milk-fed babies in that they were well digested, pasty and contained no mucus or curds except in the presence of an intercurrent infection whereas with breast milk mucus and curds in moderate amount were found.
4. There was no marked vomiting in any of the cases.
5. There seemed to be very little gaseous fermentation.
6. It was less constipating than our usual boiled milk formulæ, one case only being constipated.

From the developmental and physical examina-

FIGURE 8

Composite weight chart of cases on Similac.

tion standpoint, these babies were normal in all respects. No cases of rickets, tetany or scurvy developed, but egg yolk, cod liver oil and orange juice or tomato juice was given to prevent these. From our standpoint the indications for the use of Similac are as follows:

- (a) Babies who do not do well on other foods.
- (b) Babies deprived of breast milk early in life.
- (c) Premature babies.
- (d) Supplemental and complementary feeding cases.
- (e) Selected cases of eczema.
- (f) Babies in which there is a milk allergy.
- (g) Constipation.

We realize in presenting this analysis that our series of cases was small, but in view of the fact that our results correspond fairly well with other cases reported, we believe it to be of some merit.

In conclusion, it is our belief that dry milks and reconstructed milks are infant foods, which are of real value, because they have certain definite scientific and clinical advantages over modified milks, but we do not consider that they are the long-awaited infant feeding panacea. The contraindications to dried milks are the same as the contraindications to other milk formulæ. Especially they should not be fed unmodified in the presence of a diarrhoea, except possibly in the case of protein S. M. A. The methods of preparation make them safe milks, because of the low bacterial count, and also because they are not influenced by climatic changes. The field for the use of dried food is ever increasing and it behooves us all to see that they are not discarded before they are given a fair clinical trial.

THE ROLE OF SULFUR IN DERMATOLOGY

By FRANK C COMBES, MD, NEW YORK, N Y

From the Department of Dermatology and Syphilology, University and Bellevue Hospital Medical College Read at the Annual Meeting of the Medical Society of the State of New York held at Buffalo N Y, May 25 1932

ASTOIC of the last century with probably more wit than knowledge once said that there were three classes of skin diseases, the first, sulfur would cure, the second, mercury would cure, and the third, the devil himself could not cure My interest is in sulfur and my purpose is not so much to evaluate its efficacy in dermatology from my own personal experience, but rather to review the opinion of those who have seen fit to record their results After all, in the final analysis it is incumbent upon us to seek to establish a consensus of professional opinion regarding the value of a drug

I have reviewed the observations of many authorities, whose accuracy of clinical observation I have reason to believe was of the highest order Nevertheless, it is noteworthy how many have ascribed the most remarkable curative properties to sulfur both internally and externally which we today are unable to substantiate During the last few years a renewed interest has developed in sulfur both as an internal and external remedy in dermatology This is particularly true in Europe where much attention has been directed toward colloidal preparations

Sulfur is one of the oldest remedies known to man It was held in high esteem by the

ancients The Greeks called it therion (therion), meaning divine, not improbably from its use in religious ceremonies Homer mentions the use of sulfur baths for a skin condition with which Herakles was affected In the 16th book of Iliad we encounter a distinct allusion to its properties as a deodorizing substance Homer in the Odyssey speaking of it as "the relief of evils" mentions its use for a similar purpose, to purge the halls after the slaughter of the suitors of Penelope

Bring sulfur straight, and fire, the monarch cries,
She hears, and at the word obedient flies
With fire and sulfur, cure of noxious fumes,
He purged the walls and blood polluted rooms

There is undisputed testimony that the virtues of sulfur were not unknown to the ancient Jews, as frequent reference is made to it throughout the Old Testament where it has been translated into the Saxon term "brimstone" Because of its inflammable nature the alchemists of remote times regarded it as the principle of all combustion

The Romans appear to be the first to ap-

preciate the value of sulfur as an antiparasitic agent in the treatment of skin diseases. Ovid, Pliny and Virgil speak of sulfur vivum in the treatment of skin diseases in sheep. It appears that greater use was made of the vapor than of any of the many preparations with which we are familiar at the present day. When Galen wanted to treat his patients with sulfur he sent them to Vesuvius. Dioscorides and Pliny testify to its efficacy in bites of venomous animals. Fracastor was the first to mention its use as an adjunct in the treatment of syphilis. Its peculiar physical properties and its extensive affinities for other substances made it a favorable subject of study and experimentation with the alchemist. Many of these preparations still retain the fanciful names applied to them in the middle ages. The traditions of their medical value still linger in the popular mind and are not yet eradicated from that of the medical profession.

Sulfur is a non-metallic element and is distributed generally throughout the mineral kingdom. It is also present in varying amounts in all vegetable and animal matter. In the human body it is not only a constituent of the albuminous, fibrinous and gelatinous tissues, but of the hair, saliva, bile, urine, nails, etc. The two animal substances in which it is most abundant are cystin found in large quantities in keratin of the skin and taurin, a constituent of the bile, in which sulfur forms about a quarter of the entire weight.

It was formerly thought that sulfur had a volcanic origin, but it is now known that it is produced in nature in gypsum after a process of reduction extending over many centuries and also by the process of deposit from sulfur bearing waters. One of the world's largest deposits is located in Utah. It is over 2,000 feet square and of unknown thickness. Shafts have been sunk sixty feet without reaching the bottom.

From a medical viewpoint we are concerned in three general types of preparations, first, elemental sulfur, secondly, sulfur compounds and thirdly, mineral waters containing sulfur and its compounds. There are four preparations of the element, namely, precipitated sulfur or milk of sulfur, sulfur lotum or washed sulfur, sublimed sulfur or flowers of sulfur and colloidal sulfur.

The first and the last of these, namely precipitated sulfur and colloidal sulfur are of the greater interest in dermatology. My remarks will be limited to them. Precipitated sulfur is a fine, amorphous, tasteless, odorless powder, of pale yellow color. It is preferred to the others because of its more highly divided state and smoother texture. Occasionally found pure, it generally contains a variable

quantity of sulfuretted hydrogen and sulfate of lime. Although these impurities are well known to exist and directions are given in the older pharmacopeias for their detection and removal they are never removed and their existence is ignored in practice. Later on I will demonstrate that it is to the existence of these impurities, especially the sulfurous acid, that sulfur owes its position as a therapeutic agent and that pure sulfur is probably inert.

All sulfur is insoluble in water, nearly insoluble in alcohol, and only slightly soluble in ether and olive oil. Because of this property of relative insolubility in the ordinary liquid vehicles, it is impossible of effective application in a fluid medium. To partially overcome this disadvantage it is possible to prepare a colloidal sulfur which in addition is said to be more active than the ordinary crude element. Egg albumen or rabinose utilized in its preparation prevents the aggregation of the sulfur masses. By means of this preparation sulfur may be applied in an aqueous medium.

Its compounds are many and I will mention them on occasion when I consider their therapeutic application. It ranks next to oxygen in its powerful affinity for other elements, with which it unites.

Before we enter into a discussion of the chemo-therapeutic action on the skin we must first assure ourselves that sulfur is absorbed. We must bear in mind that it is an insoluble element and not absorbed as such by the intact epidermis. Unna supported the opinion that its favorable influence was due to the formation of hydrogen sulfide gas. Recent investigations of Heftler, Golodetz et al., have confirmed these findings. Maliva demonstrated that bismuth injected subcutaneously in mice was blackened by a sulfur bath. This conversion of sulfur is generally accepted. We are all familiar with the odor emanating from patients anointed with sulfur and acquainted with the fact that silver articles carried in the pocket are discolored due to the formation of a black sulfide. Kensuke, of Japan claims that the absorption of colloidal sulfur takes place through the epidermis *per se*, and not through the glands as is the generally accepted mode of absorption of sulfur.

According to Kopytowski, applied to the normal skin it produces an increased but incomplete epidermal keratinization with a definite marked dilatation and thickening of the vessels of the papillary layer. There is a very slight leukocytosis principally of the mononuclear cells. It differs in this respect from other chemicals which produce a chemotactic action invoking a polynuclear leukocytosis.

The chemical reactions responsible for this effect of sulfur have been variously explained. Brisson believed that it depended upon the sodium chloride content of the serum, which oxidized the sulfur to sulfuric acid, and that the latter was the active principal. Thus, the greater concentration of sodium chloride in the serum the greater the activity of the sulfur.

Sulfur is one of the most important elements found in the corneous layer of the skin. According to Unna and Golodetz the dried epidermis of the sole of the foot contains 0.53%. It is found combined with the amino-acids, tyrosin, phenylalanin and cystin. Cystin which contains about 14% sulfur is an important factor in the process of cornification. It is the principal carrier of sulfur in keratin. It readily liberates sulfur in the form of hydrogen sulfide. Besides the sulfur combined in keratin as cystin there is a larger part, loosely bound. Unna demonstrated that the loosely bound sulfur exists only in the cells having undergone complete cornification. Thus, sulfur applied to the skin in dermatoses in which there is a deficient or incomplete keratinization as seborrheic dermatitis, psoriasis, pityriasis rosea and other diseases in which parakeratosis is an important factor should act as a corrective agent. This is known as its keratoplastic action and aside from its antiparasitic action is the most important property the element possesses.

Paschkis is of the opinion that its action is enhanced by combining alkalies with it. This may explain the irritating effects of sulfur in acute vesicular dermatitis. The secretion in these cases is alkaline in reaction and sulfur exerting its maximum effect would tend to aggravate the existing inflammation. It might also explain its relative ineffectiveness in psoriasis and parapsoriasis in which the scales have an acid reaction.

The chemistry of this keratoplastic action is a process of reduction or absorption of oxygen. It is dependent upon the ability of hydrogen sulfide to combine again with sulfur, therefore forming poly-hydrogen sulfides. These combine with oxygen producing thio-sulfates. Organic sulfur compounds found in the epidermis also have a tendency to form other sulfur combinations, as for example cystin is formed from cystein by reduction. This favors normal cornification. Unna also assumes that it may be necessary for cell growth and cell division to cease, before cornification can take place, and that cessation of cell life is caused by the withdrawal of oxygen. Since the cystein-cystin reaction is reversible through a process of oxidation, the presence of hydrogen sulfide might possibly

be considered as checking this process by absorbing all the available oxygen to form sulfurous acid, thus enhancing complete keratinization.

The keratoplastic effect of sulfur is evident only in pathologic skins. Golodetz has demonstrated this by applying an ointment containing lead and sulfur to diseased and healthy areas on the same individual. The skin covered with scales and crusts was blackened according to the severity of the lesion. The blackening disappeared on recovery. The healthy skin was not blackened. This proved that the pathologic skin forms sulfuretted hydrogen when treated with sulfur through which the cystein contained in the horny skin is transformed to cystin.

The keratolytic action of sulfur may be dismissed with a few words. It is seldom used for this purpose as we have other agents which are more effective and are less liable to produce irritation. Greater concentrations of the element are necessary to elicit this action. It is due to the deep action of hydrogen sulfide on the young prickle cells, dissolving these and thinning the corneous layer. The antiparasitic nature of sulfur is largely dependent upon the keratolytic action. Its action is enhanced by heat and light, in the presence of an alkaline medium. Sulfur is frequently incorporated in soap. As time is required for the development of poly-hydrogen sulfides, the lather should be left on the skin for several hours.

The effectiveness of sulfur when applied to the skin depends physically on the size of the particles. Colloidal sulfur possesses the highest degree of division and exhibits therefore the largest total surface. I think that experience and time will prove that it is the most satisfactory preparation for application to the skin, since it can be applied in high dilution. This utilizes the favorable therapeutic action of the element and obviates the possibility of a dermatitis.

In a discussion of the therapeutic use of sulfur, we must, for clearness separate the internal from the external use of the remedies considered. Experience teaches us that sulfur is of definite value when applied externally in scabies, acne vulgaris, rosacea, tinea and seborrheic dermatitis. It is also of benefit in the pyodermas, furuncles, carbuncle and impetigo contagiosa. In this latter group it acts by withdrawing oxygen and moisture from the tissue thus rendering it less favorable for bacterial proliferation.

In addition, Paschkis recommends it in ichthyosis and pigmentary diseases, and Stelwagon in lupus erythematosus. Shoemaker

recommends it in psoriasis and pediculosis; Sabouraud, in all effections of the follicles or localized around the hair follicles. Crocker obtained good results in localized hyperidrosis with the internal administration of a drachm of the precipitated sulfur three times daily. Norman Walker recommended it in erythema multiforme, and Hardaway in dystrophies of nails. I can attest to the excellent results obtained by Trimble in sycosis vulgaris with a 1-2% precipitated sulfur ointment.

The effect of sulfur taken internally is primarily laxative, but there is definite evidence of absorption, and its presence has been demonstrated in the skin following ingestion either of the crude element or one of its salts. Bulkley and Garrod speak very highly of its beneficial effect when taken internally in peri-anal eczema. I have never seen any benefit from it in these cases except as a laxative. Pautrier reports striking results in the treatment of alopecia and psoriasis after the intramuscular injections of 1-2 c.c. of a 5% oil solution of sulfur. I have found this a very painful injection. A dextrose solution containing a sulfur compound is now available for intravenous injection.

The question of calcium sulfide has always interested me. It was first brought to the notice of the profession by Sidney Ringer over half a century ago. Since then it has had many ardent advocates and an equal number of sincere defamers. Speaking of the alkaline sulfides generally, Ringer says: "This group of remedies influences the suppurative process in a marked and manifest manner. In boils and carbuncles these remedies yield excellent results. One-tenth grain of sulfide of calcium given hourly or every two or three hours will generally prevent the formation of fresh boils, while it lessens the inflammation and reduces the area of existing boils."

Piffard and Sabouraud support this view and ascribe the failure of many to substantiate it to the fact that the dose has exceeded that suggested and that generally the sulfide is not administered in gelatin coated pills. Calcium sulfide is not a very stable or pure preparation and must be freshly dispensed. Many times the sulfite or sulfate are substituted for the sulfide. Piffard cites several instances where doses of $\frac{1}{2}$ -1 grain had no effect or caused an apparent aggravation of the process. When doses as small as 1/10-1/50 grain were administered, prompt improvement followed. Most dermatologists at the present day agree with Ravitch that the reports of its great therapeutic value are simply myths. I cannot ascribe entirely to this attitude as I have seen many cases of definite improvement following its use in doses of 1/10 grain dispensed in

small gelatin capsules. Piffard claimed excellent results in acute eczema in infants with calcium sulfide in doses of 1/100 grain. Bulkley, G. H. Clark, Hardaway, Grindon, Radcliffe-Crocker and many others also considered it a valuable remedy.

Sulfur baths are of undoubted value in vesicular and pustular dermatoses. Osterberg, Rubenstein and Goeckerman have reported excellent results and consider them a valuable addition to the therapeutic armamentarium. Further they have demonstrated that sulfur administered in this fashion is absorbed both by the skin and inhalation. I have experienced the rather embarrassing experience in having patients with an apparently intractable dermatosis recover completely after a few weeks sojourn at a sulfur spa.

Natural sulfuretted waters are available in New York at Richfield, Sharon and Avon. Duhring reports that the manner in which they act is not always clear, but that cures often take place through bathing cannot be questioned.

In syphilis I think that sulfur baths are also of great value. The conventional disagreeable salts formerly used for this purpose have been replaced by modern compounds both of a colloidal and non-colloidal nature which are non-staining and almost odorless.

Vlemminckx's solution (Liq. calcis sulfuratae) makes a good sulfur bath. From six to eight ounces to the tub of water is sufficient for an adult. It should not come in contact with the nickel fixtures or they will tarnish as the result of the action of the hydrogen sulfide liberated. The *modus operandi* is rather obscure, but there is definite evidence that it increases the tolerance to mercury. McMurtry expressed it as keeping a "stream" of mercury going through the cells. Schlesinger in 1931 claimed that it acted as a catalyzer to the mercury and found it of great value as an adjunct in the treatment of visceral syphilis, particularly aortitis. I have no doubt but that the patients in general are benefited by it and are better able to tolerate the conventional anti-syphilitic drugs. It may be administered by mouth or intravenously. I do not recommend that it be given simultaneously with the arsphenamines as it may act in too rapid elimination of the arsenic.

In 1927 Schroeder of Denmark reported excellent results following the injection of sulfur in the treatment of paresis by hyperpyrexia. The intramuscular injection of 5 c.c. of a 2% suspension of sulfur in olive oil is followed in about six hours by a temperature ranging up to 104°, which is sustained and falls gradually over a period of 18-24 hours. I have had encouraging symptomatic and

SERVICE OF EX-PRESIDENTS

Doctors are often accused of being failures as business men, diplomats and politicians. They are failures as business men if the yardstick of making money out of their profession is the measure used. The standard of saying and doing what the patients want would find

the doctor deficient as a diplomat. The average doctor does not shine as a politician, advocating public measures for the sake of their notoriety and advertising value. Yet the established custom of the medical profession is advocated by Walter Lippman, former editor

of the New York World, in an article in the September American, entitled "Good Men Wanted." Mr. Lippman suggests that Calvin Coolidge and other ex-presidents set an example of public service by seeking to become members of Congress, or other offices of lower rank.

The established custom of the Medical Society of the State of New York, is that its ex-presidents shall accept appointments as chairmen or members of committees, thus continuing to give their services to the profession and the public unselfishly and for the promotion of public health.

ULTRA-VIOLET LAMPS IN THE HOUSEHOLD

An advertising concern has recently issued a news item "for immediate release," whose opening sentence is "A new electric bulb similar to a lighting bulb, that produces the safe ultra-violet health rays at low cost for domestic use, has just been announced."

Then follows the statement that a public health worker had "discovered a close relationship between the varying amounts of sunlight throughout the year and seasoned increases in illness," and therefore this expert advocates the use of artificial sunlight as a means of reducing illness during winter and spring.

The people have been fed with these half or quarter truths to such an extent that they expose themselves for hours to sunlight on the beaches and on house roofs, and then, a few hours later, suffer with chills, fever, vomiting, and other signs of an acute burn.

Every doctor who gives ultra-violet treatments is aware of the precautions which he must take in order to prevent sunburn. He limits the time of the first exposure of a part to only five minutes, lest he "burn" the patient. Yet the people use ultra-violet lamps supposing that they will do no harm even if they do no good.

The doctor who seeks to instruct the public regarding the nature of ultra-violet light is in a dilemma. He wishes the people to know the curative value of the light, as well as its limitations; and he does not wish to emphasize its dangers to such an extent that the people become panicky and refuse to take the treatments when they are required. Probably the best course for him to follow is to warn his patients privately of the dangers of ultra-violet burns as well as sunburns; and to advise them to take the ultra-violet treatments on the doctor's prescription only.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Typhoid Fever: This Journal of September, 1907, contains an editorial on typhoid fever which assumes that its complete eradication will occur in the near future, when it says:

"Some day typhoid fever will be as obsolete in civilized communities as cholera or small-pox. We possess all of the information that is necessary to make it so now. It is no longer a great and elusive mystery. The average third year medical student knows enough about typhoid fever to be able to stamp it out in any municipality if he might have absolute power.

"Every case of typhoid fever is an evidence of the benighted state of the civilization in which it occurs, and of the inefficiency of the government."

The editor assumed that complete prevention might be impossible because of interstate commerce, and says:

"If a municipality should grant to its health

commissioner all of the authority necessary to this end, he could cut down the typhoid death rate to a minimum, but beyond a certain point he could not go without the aid of the State.

"In Pennsylvania particularly, and in New York State, too, railroad cross the streams from which towns take their drinking water, and every coach on every train of cars crossing these streams has a toilet which is used by typhoid convalescents. We have already referred to the positive knowledge which we possess concerning the railroads as distributors of typhoid, but not enough attention is paid to this important factor. The streams and brooks which supply the ill-fated City of Scranton with drinking water are crossed and recrossed by the railroad which daily carries hundreds of people from Philadelphia, the asylum of typhoid; and still the investigating authorities declared that they could not specify the source of the Scranton epidemic."

MEDICAL PROGRESS

Renal Glycosuria.—In the selection of cases of "typical" renal glycosuria here reported Alexander Marple has chosen the following standards: (1) Glycosuria without hyperglycemia. Sugar should be found in every specimen of urine voided, whether in the fasting state or after a meal. The amount of sugar excreted in twenty-four hours is of little importance. No fasting blood sugar value (venous) may be 0.12 gm. per 100 c.c. or over, and no blood sugar value after a meal may be 0.17 per 100 c.c. or over. (2) Glycosuria should be largely independent of diet, but may fluctuate somewhat, depending upon the amount of carbohydrate ingested. (3) The level of blood sugar should be influenced only slightly by the ingestion of food. The curve obtained after giving 100 gm. of dextrose should be a normal one with no value rising to 0.17 gm. per 100 c.c. and with a return to the control value within two hours. (4) The symptomatology characteristic of diabetes mellitus should be absent. (5) The type of sugar found in the urine should be proved to be dextrose. (6) No progression toward true diabetes mellitus should be evident during an arbitrarily chosen period of at least three years. (7) For complete study it should be shown that the patient is able to store and utilize carbohydrate in a normal manner. A common finding, not necessary for diagnosis, is the history of glycosuria occurring in the relatives of the patient. Only 15 cases in a study of 9,000 cases of glycosuria were found which fulfilled the requirements outlined: In addition 7 cases were found which were considered typical of renal glycosuria except for an occasional sugar-free urine specimen or an exceptional blood sugar value above the limit of set in the Joslin Diabetic Clinic. Two cases of chronic ("essential") pentosuria were discovered among the patients with supposed renal glycosuria. No case in the group had recognizably progressed toward diabetes mellitus, despite the fact that of the 15 typical cases 5 had glycosuria for over ten years and 1 for over thirty-six years. In 13 of the 15 cases glycosuria was first noted before the age of thirty years. In 3 cases the onset was noted before the age of ten years, and in 9 before the age of twenty years. The history of glycosuria in any of the relatives of the patient was obtained in 11 of the 15 cases. No evidence of nephritis was found in any of the patients. Because of its rarity care should be exercised in making the final diagnosis of this type of glycosuria. When the diagnosis is tentatively made the patient should be carefully followed. Tests of the blood and urine should be made every three months for the first year and

every six or twelve months thereafter.—*American Journal of the Medical Sciences*, June, 1932, clxxxiii, 6.

Abstinence Symptoms with Atropine.—Hardly any attention has been given hitherto, says Robert Flinker, to abstinence symptoms following withdrawal of atropine. He has recently had occasion to observe simultaneously the symptoms that developed in 2 patients as the result of the accidental interruption of the administration of large doses of atropine, when through some oversight the atropine solution in his department was used up and a fresh supply could not be provided immediately. Both patients were suffering with parkinsonism; one was receiving 3 times a day 25 drops of a 0.5 per cent solution of atropine sulphate and the other 18 drops of the same solution, likewise 3 times a day. After sudden withdrawal of atropine there appeared in both patients, 8 and 13 hours afterward, respectively, symptoms consisting of malaise, nausea, vomiting, vertigo, profuse perspiration and salivation. These phenomena persisted all the following day, and did not come to an end until, for lack of atropine solution, 0.06 gm. ext. belladonna was administered. They disappeared completely on the second day afterward, shortly after the patients had received their customary doses of atropine. We are therefore driven to regard these symptoms as abstinence symptoms. It is only rather recently (1925) that the medical profession has learned to treat encephalitic patients with large doses of atropine. In the author's clinic a daily administration of 20 mg. (3/100 grain) is not unusual. It can hardly be wondered at that a sudden interruption of this dosage may have a very different effect from that which would follow interruption of the usual small doses. These experiences teach that a warning is necessary not to allow such patients to be suddenly bereft of their medicament upon discharge from hospital care.—*Münchener medizinische Wochenschrift*, April 1, 1932.

Phototherapy in Erysipelas.—J. M. Davidson presents a report of fifty-one cases of erysipelas treated by exposure to an artificial source of ultra-violet light. This treatment, particularly in the early case, appeared to give better results than other methods in use. The method is easily applied, devoid of danger, cleanly, and inexpensive. Before treatment was commenced any preparation previously applied to the part, especially if it were greasy, was carefully removed from the affected area. One and a half times to twice

the erythema dose was employed, the exposure being for five minutes with the arc at a fixed distance of twelve inches. In the case of infants a slightly shorter exposure was employed. In all cases part or all of the inflamed area, according to its extent, was included in the exposure, with a margin of about one and a half inches of healthy skin when this was possible. In facial and head cases, the eyeballs were protected by small pads of cotton wool fixed by adhesive plaster. Following light treatment, the affected part was left uncovered, or at least without dressings, except in two instances in which pain was a prominent feature, and in these lint wrung out in cold water was applied and frequently renewed. By the end of forty-eight hours after exposure there was a critical fall in temperature in 31 of the 39 cases in which the whole edge of the lesion was treated. In 23 of these cases the fall commenced within twenty-four hours. Of the 51 cases 4 terminated fatally; these were all complicated cases. In the remaining 47 cases the average duration of the fever was 7.81 days, while in 47 control cases the fever lasted 9.26 days. The average duration of the fever after treatment was 3.85 days, in the control cases 5.16 days. The sole complication seen in the treated cases was streptococcal abscess, which occurred in two cases. From the results in these cases it would appear that if acute cases of erysipelas come under treatment sufficiently early prompt exposure of the affected part to what is customarily considered an over-dose of ultra-violet light would, in the large proportion of cases, abort the lesion. The technique can be carried out with any ultra-violet lamp of known efficiency.—*British Medical Journal*, May 21, 1932, i, 3724.

The Dangers of Overdosage with Insulin in Treatment of Liver Affections.—Bernhard Kugelmann, writing in the *Deutsche medizinische Wochenschrift* of April 22, 1932, makes a report on some experiments that he has carried out with a view to studying the effect of rather large doses of insulin upon the liver function in healthy individuals. He proved that large doses of either insulin or adrenalin produce demonstrable disturbances of the carbohydrate metabolism of the liver. If, however, small doses (5 units) of insulin were injected, the normal blood sugar curve was found unchanged after a levulose functional test. On the basis of 2 cases Kugelmann shows that if patients suffering with liver affections (icterus simplex, acute yellow atrophy with suppurative cholangitis-cholecystitis) are treated with insulin, the administration of large doses has the opposite result to that intended. Instead of enriching the liver with glycogen, the organ is injured still more. Only with small doses of insulin (5 to 10 units twice a day), administered subcutaneously, never intravenously, and with

simultaneous administration of an abundant carbohydrate diet, with glucose or even cane sugar, can a glycogen fixation be achieved, and with it a support of the liver parenchyma. Under all circumstances the slightest sign of hypoglycemia must be avoided. If these appear after 5 to 10 units of insulin, as does frequently occur in liver patients, it is better to abandon insulin treatment, for it can only injure the patient. Care must also be taken not to give too large doses of sugar (100 gm. or more) to a patient who is receiving insulin, for these may increase the effect of the insulin by causing endogenous insulin production. Endogenous added to exogenous insulin may result in severe hypoglycemic conditions. It is therefore wiser not to give more than 40 to 50 gm. sugar. What is wanted in liver disease is to fill up the glycogen depots in the liver. This is best done by subcutaneous injection of small doses of insulin, and avoidance of too much sugar administration.

The Action of Lecithin and Cholesterin Associated with Insulin upon Carbohydrate Metabolism.—Umberto Polera states that he carried out a series of experiments upon 4 diabetic and 4 nondiabetic subjects, to determine the effect of lecithin and cholesterin upon carbohydrate metabolism, when associated with insulin. He found that in the diabetics the hypoglycemic action of insulin is markedly increased when it is associated with lecithin and with cholesterin. This increase occurred independently of whether the insulin was associated with one alone or with the two together of these substances, except in one case, in which the simultaneous administration of the three substances doubled the hypoglycemic effect. The reduction of blood sugar content began after 30 minutes, and reached its peak as a rule in 90 to 120 minutes. In the nondiabetic subjects an increase of the hypoglycemic action of insulin was similarly observed when insulin was associated with lecithin or cholesterin, but in less degree. Here, however, the increased hypoglycemic effect was more marked when insulin was associated with cholesterin than when it was combined with lecithin. The association of all three at once gave the same result as insulin and cholesterin without lecithin. Beginning after 30 minutes, the action reached its peak nearly always after 90 minutes. The marked lowering of the blood sugar content in these nondiabetic subjects was not accompanied by symptoms of hypoglycemia. Obviously this increase of the property of insulin to reduce blood sugar when administered in association with these substances requires an explanation. In the light of modern research it appears that the syndrome of hypoglycemia is related not to the blood sugar values but to diminished supply of glucose to the cells, or a diminished capacity on the part of the cells to utilize glucose,

which is followed by the formation of intermediate spasmogenic substances. It appears that the lipoids may either favor such utilization by the cells or may act to prevent the formation of these spasmogenic substances. It seems probable that the increased hypoglycemic property of insulin associated with lecithin and cholesterol together is due to a neutralization of the circulating adrenalin by the lecithin, and that the failure of hypoglycemic syndromes to appear is due to a greater utilization of the glucose by the cells, or to a neutralization of spasmogenic substances by the lecithin and the cholesterol. It is certain, however, that we are still in the field of hypothesis here, since in fact we do not even know more than hypothetically what metabolism itself is.—*Riforma medica*, April 23, 1932.

The Management of the Decompensated Cardiac Invalid.—Harold Thomas Hyman and Nathan M. Fenichel, writing in the *American Journal of the Medical Sciences*, June, 1932, clxxxiii, 6, discuss the cardinal principles in the management of the cardiac invalid with respect to the effects of specific medication as observed in a series of 100 cases. They emphasize the importance of institutionalization and dietotherapy in securing physiological rest, together with the liberal use of sedatives and hypnotics. Drug therapy is indicated in the cardiac invalid who remains decompensated despite rest, dietotherapy, and the mechanical evacuation of fluid from the serous cavities. Digitalis is invaluable in patients with auricular fibrillation. The pharmacology of the digitalis group of drugs may be simplified to a great extent by eliminating all of the preparations other than the tincture and the leaf of digitalis, and by administering these only by the oral or rectal route. The dosage cannot be estimated by any *a priori* calculation. This opinion bears out the original writing of Withering who said, "Let the medicine be continued until it acts either on the kidneys, the stomach, the pulse, or the bowels—let it be stopped at the first appearance of any of these effects." Diuretics are of equal importance to digitalis in the management of the decompensated cardiac invalid. Their use is independent of the cardiac rhythm. The problem of diuretics may be simplified by eliminating all but the saline preparations (urea and acid salts) and the mercurials, such as salyrgan. In several instances urea has been administered over a period of years despite the elevation of the blood urea figures to as much as 105 mg. per 100 c.c. There have been no untoward reactions other than an occasional urea rash, which disappeared when the drug was discontinued. The acid salts (ammonium chloride or carbonate and calcium chloride) are given in dosages of 10 grams daily. They are indicated when edema persists, despite digitalization, rest, and the limitation of fluids

and salt in the diet. Second only to digitalis in the management of the decompensated cardiac invalid are the mercurial compounds. The authors prefer salyrgan, which can be administered intramuscularly or intravenously in doses of 1 to 2 c.c. They do not hesitate to employ the drug in the presence of marked albuminuria, even when it is accompanied by casts or an occasional red cell. The dose may be repeated in four or five days, though it is preferable to wait a week if this is possible. The cardiac stimulants, caffeine, strychnine, camphor, and adrenalin are definitely valueless in the management of the decompensated cardiac invalid. Adrenalin is absolutely contraindicated. Liberal doses of morphine and other sedatives are helpful.

The Need of Occupational Therapy for Cardiac Patients.—Paul D. White, writing in the *New England Journal of Medicine*, May 5, 1932, ccvi, 18, holds that there is no doubt at all concerning the need of occupational therapy for cardiac patients, no matter what the kind of heart disease, what the age, and whether the patient is convalescent or acutely ill. In acute cardiac illness, as soon as the necessity for absolute rest has passed, some form and degree of occupational therapy is valuable and much too often neglected. The occupation selected need not be useful from the ordinary utilitarian point of view. For example, reading or being read to, sketching or painting, writing letters, stories or poems, keeping a diary of current events, playing chess or other games, making or solving picture or cross-word puzzles, collecting flowers, minerals, beetles, or stamps, and gaining knowledge of some phase of archeology, history, literature, science, or art. may be more worthwhile than weaving baskets, sewing, or making pottery. The occupation must suit the age, intelligence, and strength of the patient. At first the mind may be allowed more activity than the body, remembering that an over-tired brain and nervous system may react unfavorably on the heart. Gradually, as the patient progresses, physical exercise should be combined with mental activity, for it is the proper mixture of the two that is best. White is a firm believer in the value of physical exercise in cardiac patients whose hearts can stand it—and they make up about 95 per cent of the lot. As examples of combined exercises he suggests strolling in search of various kinds of flowers, trees, rocks, insects, or birds. In selecting forms of occupational therapy it is important to plan for the future, so that there need be no break later on, but a permanent occupation, be it vocation or avocation. Most cardiac patients are not sufficiently crippled to change their present occupations, though they often need reassurance and a little directing here and there. Every case must be managed on its own merits. No rules can be fixed.

The Treatment of Habitual Obstipation.—All therapeutic measures for the cure of constipation, says E. Renold, should have as their aim the achievement of a stool which approaches as nearly as possible a natural emptying of the bowel with reference to frequency, size, and form. Even habitually obstipated individuals can be trained to have a sufficient bowel movement every day at a given time without difficulty, pain, or excessive strain. The choice of diet is of very great importance. In the case of persons who have abused laxatives, and consequently have a refractory intestinal tract, the diet should be bland, non-irritating and free from sediment, even potatoes being omitted at first. For a few days it is advisable not to give per os any remedy exciting peristalsis, but to have recourse every second day to an enema after breakfast, with camomile or flaxseed incorporated when the bowel is very sensitive. After a few days small amounts of filling or lubricating remedies that do not cause fermentation may be cautiously given, among the best being psyllium. Flaxseed drinks and agar-agar preparations are also suitable, provided they do not contain purgatives. It is advantageous to employ a filling substance that acts chiefly through its swelling capacity, together with a lubricant that softens the feces. The latter substance is found in paraffin, provided it is given rationally, in small doses distributed over the day and not too far from meal time. It is impossible to emphasize too much the necessity of educating the bowel to punctual emptying. The patient should go to the toilet every day at the same hour, preferably after breakfast. If, however, the desired result is not obtained after 10 to 15 minutes, it should be made a rule not to make any further attempt on that day—unless of course the urge is overwhelming. Enemas or suppositories should always be given in the morning. Evening use may, however, be made advantageously of small rectal injections of oil or paraffin. In cases of atony, massage is useful. This should be done slowly with the flat of the hand and always with caution and avoidance of rough manipulation. Its use belongs to the expert, and is the proper province of the trained physician. In cases of simple sluggishness, particularly in young persons not slaves to laxatives, cellulose treatment is advisable, with such foods as potatoes, green vegetables, fruit, salads, and bran. The eating of 6-10 dried prunes in the evening on an empty stomach may accomplish results if the case is not an obstinate one. With patience on the part of physician and patient there are few cases that will not attain the correct rhythm in at most a few weeks.—*Schweizerische medizinische Wochenschrift*, May 14, 1932.

A Case of Graves' Disease Treated by Removal of the Inferior Parathyroids.—An unusual case is reported by Gaudier and Minet, in a paper read before the Paris *Académie de Médecine* of April 5, 1932, in which removal of the two lower parathyroid glands in a woman of 38 suffering with exophthalmic goiter caused the spontaneous disappearance of all her symptoms within a month following operation. The thyroid tumor had been growing for about six months, chiefly on the right side, where it had attained the size of an orange; a prolongation about the size of a thumb extended toward the left from the thyroid mass, adherent to the trachea. The usual symptoms of exophthalmia and tachycardia were present; there were diplopia, ready fatigue of the eyes on reading, and persistent headache; the tachycardia appeared in crises, accompanied by dyspnea and insomnia. Tremors, abundant perspiration, and pruritus added to the patient's sufferings. Her state of emaciation and inanition was so excessive that an emergency operation seemed indicated as the dyspnea increased. What operation to perform was, however, a problem, as the patient could not bear a thyroidectomy, and yet her respiratory troubles urgently demanded relief. While examining the inferior thyroid arteries with a view to the feasibility of ligating them, Gaudier observed that the right inferior parathyroid was sensibly increased in size, resembling a small almond, and the left one also somewhat enlarged; both were of hard consistency and of a color resembling ham. He removed both these organs without ligating the principal vascular trunks except those that had been cut during the dissection of the region. He did not touch the goiter, and reconstituted the region in three layers. Improvement of the general condition appeared immediately; the pulse, which had averaged a beat of 140, dropped to 100 and less; the dyspnea so promptly yielded that the patient was able to get up on the third day, and on the fifth to stay up all day. At the end of a month, to the astonishment of both Gaudier and Minet, the exophthalmia had ceased to exist; the goiter and also the tremor had disappeared; there was no dyspnea, and the pulse was between 70 and 90. The authors are inclined to believe with Leriche that there is a connection between parathyroid and vasomotor functioning. It was this consideration that led Gaudier to think that a partial intervention upon the parathyroids would do as much good, or more, than ligation of the vascular pedicles of the inferior thyroid trunks, which had not in the past given him very good results. Histologic examination of the removed parathyroids revealed lesions of sclerosis.

LEGAL

EVIDENCE — IMPROPER QUESTIONS AS TO PHYSICIAN'S WEALTH

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

It has long been one of the well-established principles of law that testimony which has no part in the issues involved in the trial of a lawsuit and serves no purpose in the case other than to "excite the passions, arouse the prejudices, awaken the sympathies or warp or influence the judgment of the jurors" must not be placed before the jury.

The Appellate Courts have in numerous cases ruled such testimony to be grounds for a reversal on appeal. A recent malpractice case tried in a nearby state illustrates well the application of the rule.

A married woman injured the calf of her leg in some manner by a blow from an automobile, and a lump described as being the size of a goose egg appeared on the inside of the tibia where the leg was struck. The lump became badly discolored, and from time to time she was treated at her home by a certain Dr. H. At the end of about four weeks the swelling had become somewhat less and the flesh had turned to a light yellow color. She was advised by Dr. H. to continue to stay in the house. Apparently because she felt that some other physician would allow her more freedom she called in a Dr. C. After his examination he told her that she was suffering from a hematoma, and that in his opinion it should be opened. According to the patient's story he also told her it would require no more than a pin prick incision. She requested that the hematoma be opened and the doctor stated to her that he had no instruments with him, but said he might undertake the treatment with a safety razor blade. He was furnished the blade, which he sterilized by boiling, and after carefully washing his hands, he incised the hematoma and dressed the wound. The doctor was paid his fee and saw no more of the patient. Apparently because the patient was disgruntled that the incision was larger than she had anticipated, she did not call Dr. C. again. The first doctor resumed the care of the case instead of Dr. C. An infection developed and it was necessary for the patient to enter a hospital for further incision and drainage. The injuries were slow in healing, and she was left with a scarred and shrivelled leg.

The patient sued Dr. C. claiming that he had been negligent in his treatment and that as a consequence she attributed to him the bad end result. When the case was tried she testified that she

had been caused mortification by reason of her unsightly limb. She claimed that she had been unable to bathe bare-legged in accordance with the dictates of fashion, but instead had been obliged to wear stockings. She also testified to an incident when she had gone bathing wearing stockings and had been ejected from a pool at the complaint of other bathers who were suspicious of the condition of her leg.

The doctor's defense included testimony that the infection had already started when he treated the patient, and that he had taken every possible precaution to guard against infection and to insure asepsis. In the cross-examination of the doctor he was asked a question as to what he considered his net worth in money to be. His counsel vigorously opposed the question but the court directed him to answer. His testimony was that he was worth over \$100,000. The case went to the jury and a substantial verdict was returned in favor of the plaintiff.

An appeal was taken on behalf of the doctor from the judgment, principally on the ground that the trial court had improperly permitted testimony to be introduced which necessarily had an improper influence upon the minds of the jury. The trial court had made its ruling on the theory that punitive damages had been asked for in the plaintiff's complaint, and therefore in order to be able to assess such damages it was proper to acquaint the jury with the wealth of the defendant. The Appellate Court decided, however, that the ruling of the lower court was improper. The record showed no evidence to sustain the assessment of punitive damages against the defendant, assuming that liability existed, there being no proof of malice or improper motive toward the plaintiff on the part of the defendant.

The Appellate Court distinguished from the case before it the type of case where the wealth of the defendant might be a proper part of the testimony. Such a case would be an action for slander, for it would be clear that the slanderous words would injure the complaining party more if uttered by a man of wealth than if the same words were uttered by the village drunkard. In such a case also malice is closely associated with the wrong charged, as distinguished from the ordinary case of alleged malpractice. As the court said:

"Where malice or a wrongful motive exists, punitive damages may be recovered. Proof of

facts showing the existence of malice lays a foundation for punitive damages. Outside of these exceptional cases where wealth is necessarily involved in determining the damages sustained, evidence of wealth is inadmissible unless there be proof of malice. It is a cardinal principle of our jurisprudence that the rich and poor stand alike in courts of justice. Neither the wealth of the one nor the poverty of the other is permitted to affect the administration of the law."

The law of New York is clearly in accord with this ruling. Some years ago a case was brought against a very wealthy man to recover damages for a death alleged to have been caused by his wrongful act. He was cross examined as to his control of various railroads, the number of banks in which he was a director, his dealings in stocks, the amounts of money loaned by him and the like, and the result was that the Court of Appeals ruled such evidence highly improper and prejudicial.

The courts of this State have decided that the rule cannot be avoided by indirect proof of the wealth of the defendant. A simple illustration of such an attempt to evade the rule and by indirect proof inform the jury as to the wealth of the defendant is found in a case decided in our Appellate Courts a considerable number of years ago.

The action was to recover damages for injuries sustained when the plaintiff was run over in New York City by the defendant's sleigh. In the course of the trial, on cross examination the defendant was asked what the horses he had been driving had cost him. He testified that one of them had cost \$3,000. As a consequence the jury awarded large damages to the plaintiff, probably feeling that any person who could spend \$3,000 in those days for a single horse would not miss the amount of damages assessed against him, regardless of the merits of the plaintiff's cause of action. The Appellate Court in said case ordered a new trial ruling that the effect of such testimony was to materially prejudice the defendant.

The rule enunciated in these cases is still considered sound, for very recently one of the Appellate Divisions of the Supreme Court made a similar ruling, and expressed its disapproval of these tactics in the following language:

"Counsel well knew that this evidence was incompetent, and it is apparent that his only purpose in offering it was to play upon the sympathy of the jury. Such conduct has been repeatedly condemned by the courts. Attorneys who persist in getting before the jury incompetent evidence for ulterior purposes should understand that their conduct will imperil any verdict which they may obtain."

DEATH FOLLOWING TONSILLECTOMY

A young man consulted the defendant in this case, who was an ear, nose and throat specialist. The patient was found to be suffering from large and badly infected tonsils, and the doctor recommended and performed an operation for their removal under a local anesthetic. The operation was successful, and the patient apparently making an excellent recovery was permitted to go home the following morning.

However, the same day that the patient returned to his home, the doctor was called to attend him on three different occasions because of persistent bleeding from the mouth. The doctor finally removed the patient to the hospital a second time, and efforts were made to check the bleeding. The following day the doctor conferred with the patient's family physician, and it was decided that the patient needed a blood transfusion. One of the members of the hospital staff gave the patient a transfusion, but the patient became delirious an hour or two after the transfusion and went into a coma, dying the same day.

No autopsy was performed on the man, but the doctor ascertained that apparently the patient had been suffering from a cardiac trouble of long standing, and that his death resulted from said condition combined with the administration of the blood transfusion.

An action was instituted by the patient's administrator charging that the negligence of the defendant doctor had been the cause of the death of the patient. After the defendant's answer was served, the plaintiff did nothing to press the case for trial and after some years had elapsed a motion was made to dismiss the complaint for lack of prosecution. The judge granted the motion with the proviso that if the plaintiff should serve a notice bringing the case on for trial for the next term of court the case would not be dismissed. However, the plaintiff failed to notice the case for said term of court, and judgment dismissing the plaintiff's case was finally entered in favor of the defendant physician, thus terminating the case.

NEWS NOTES

DISTRICT BRANCH MEETINGS

The tentative schedule of the meetings of the District Branches was printed in this Journal of July first, page 818. Unforeseen contingencies often arise which necessitate changes in the programs. The revised schedule is as follows:

First—Sparkhill—October 14th.

Second—Garden City—November 17th.

Third—Loomis Sanitarium, Liberty—September 21st.

Fourth—Schenectady—October 11th and 12th.

Fifth—Oneida—October 4th.

Sixth—Binghamton—September 27th.

Seventh—Clifton Springs—September 29th.

Eighth—LeRoy—October 6th.

FOUR-COUNTY SOCIETY MEETING

A joint meeting of Livingston, Orleans, Genesee and Wyoming counties medical societies was held at "The Barn" at LeRoy, N. Y., on Wednesday, July 27th.

The afternoon was devoted to bridge for the ladies, golf, and pitching horseshoes for the men. Prizes were given in both auction and contract bridge. The silver cup for golf went to Genesee county.

At seven o'clock a bountiful chicken dinner was served in the banquet room with one hun-

dred and four in attendance. After dinner the principal speaker of the evening, Dr. Charles Brown of Ann Arbor, Michigan, gave a most interesting talk on "Problems of Peptic Ulcers." Discussions were given by Dr. George Eckle of Buffalo, Dr. Thomas Walsh of Buffalo, and Dr. Klostermyer of Warsaw.

The secretary of each society was asked to get the opinion of members of its society in regard to making this joint meeting an annual event.

GEORGE M. DOOLITTLE, M.D., *Secretary*.

ROCKLAND COUNTY

The Rockland County Medical Society holds a summer meeting which combines science and sociability. The meeting this year was held on August 25, in the Summit Park Sanatorium, the Rockland County tuberculosis hospital, at Pomona.

A scientific meeting was held at two o'clock in the Recreation Hall of the Sanatorium. The subject of the relation of the county medical society to public health was presented by three speakers:

1. Dr. Thomas P. Farmer of Syracuse, Chairman of the Committee on Public Health and Medical Education of the Medical Society of the State of New York, set forth the civic responsibility of the county medical society in local public health activities.

2. Dr. O. W. H. Mitchell of Syracuse, member of the Committee on Public Relations of the State Medical Society, told of practical methods by which the County Medical Societies had cooperated with boards of supervisors, school boards, officials of towns and villages, and other public officers, and also with lay health organizations, in carrying on public health work.

3. Dr. Thomas Parran, Jr., of Albany, State Commissioner of Health, emphasized the

friendly relations between the State health officials and the practicing physicians, and complimented the doctors of Rockland County for their active interest in public health movements.

The practice of clinical medicine was represented on the program by a paper on The Therapeutic Use of Suprarenal Extract in Addison's Disease, by Dr. Clayton W. Greene, of Buffalo.

The social program of the meeting consisted of a clambake prepared and served in the grove of the Sanatorium according to the ancient ritual devised by Dr. George A. Leitner.

Dr. W. J. Ryan, Superintendent of the Sanatorium, showed the June issue of the "Summit Park Outlook," a quarterly publication conducted by the patients in the Sanatorium. It consists of eight pages and a cover. Five of the pages are filled with personals about the patients, nurses, and doctors. There is a message of cheer by Bruce Barton, and an abstract of a scientific paper by Dr. Alfred Henry, President of the National Tuberculosis Association. The "Outlook" will make a strong educational and inspirational appeal to the people of Rockland County.

W. J. Ryan, *Secretary*.

THE DAILY PRESS

SIGNS OF BETTER TIMES

The bulbul, or Persian nightingale, is no imaginary creature, but is a real songbird whose return after a long winter's migration is a cheerful omen of Spring. Though prosperity departed two or three years ago with the stealth of the autumnal flight of the summer birds, the first evidence of its return has already been hailed with song and joy, as is depicted by J. N. Ding in the *Herald Tribune* of August 8, 1932. The cheerful twitterings of the Wall Street bull, replacing the grumble of the bear, is peculiarly encouraging to physicians whose collections have often been in inverse ratio to the number of calls they have been compelled to make. They sincerely hope that Ding's picture of the singing bull, and the flock of hogs soaring in price, is no mere nightmare, but is a real harbinger of better times at our door.

The stock market is a thermometer whose readings by financial doctors must be interpreted in their relations to other conditions besides the heat of speculation or the coldness of panic. Physicians are often said to be poor business men; but their local credit is better than that of ninety per cent of their fellow citizens. The law of supply and demand will always operate in favor of the doctor, for pain and sickness are always rampant in every community, and the doctor's services are always in demand. He is sure of having plenty to do—which is more than the merchant or the manufacturer can expect in his business.

WHAT IS INTOXICATION?

The *New York Times* of July 31 asks the question: "Is there any basis in science for considering an alcoholic content of more than one-half of one per cent intoxicating?" It comments on the question as follows:

"One may search old and recent records in vain for a definite answer to the first of these questions. So far as can be learned, no scientific study by an unbiased group ever has been conducted to determine what alcoholic content of beverages is intoxicating.

"The standard of one-half of one per cent alcoholic content had been used by the United States Government for revenue purposes since 1902, or for seventeen years longer than prohibition has been effective. According to one authority, the same standard was used by about

thirty of the thirty-three States which had adopted prohibition within their borders prior to the passage of the national prohibition act. There is, however, a broad question as to whether a standard set for revenue purposes is necessarily the one that need be applied to a social law.

"The next session of Congress, especially if new wet accretions are shown in the November elections, probably will see the first sincere step taken to determine actually what may be considered generally as intoxicating, with a view to adapting the law to whatever findings may be revealed.

"If that is done, it will settle in a scientific manner a question that otherwise has been taken for granted without the benefit of research for almost a century."

PRIMITIVE MEN OF MOUNT CARMEL

The discovery of a group of skeletons of primitive men in a cave in the foothills of Mount Carmel recalls the successful contest of the Prophet Elijah with the hundreds of priests of Baal on top of the mountain, as recorded in Chapter 18 of the first book of Kings. Commenting on the discovery the *New York Times* of August 14, says:

"No ancestors of Elijah were these extinct men, but Neanderthals who differed as much from those in Europe as Arabs of our day differ from Germans. They had the thick, beetling brows, the shuffling gait, the stoop of their European contemporaries, but they were set apart by their chins, their higher foreheads, the backs of their heads, their deep, heavy jaws, their modern faces. Because of their distinctiveness Sir Arthur Keith considers them worthy of a special name, *Paleanthropus Palestinus*.

"Despite their groping toward civilization, evidenced by their tools and their familiarity with fire, nature tossed these Galileans aside. Out of such stuff no Shakespeare, Beethoven or Edison could be fashioned. We look at the Java Men, Chinese primitives, Rhodesian Men, Heidelbergers, Chelleans and others that have come and gone, only to realize that there was something genetically unstable in the first anthropoid. No wonder the scientists like Keith ask what man will be like a million years hence. Tossed on the sea of circumstance, carried forward in the past by forces of which he knew nothing, do his cumulative discoveries about himself and his environment show that some day he will learn to direct his own evolution? That the question can even be asked indicates how far the race has progressed since the extinct Galileans were buried on Carmel."

PROFESSIONAL PRIDE

Although doctors are inclined to be a grumpy lot when they talk among themselves, yet in their hearts they give thanks that they are apart from their lay brethren, and fortunate above those not

in their professional fraternity. That self-esteem is a good quality is shown by the following verses in the *New York Herald Tribune* of August fifteenth:

"The locust doubtless thinks that he
Is just as useful as the bee.
Although he does not furnish food
For either man or his own brood.
The grackle in the underbrush
Remarks the singing of the thrush
Perched high upon a maple limb,
And says, 'I sing as well as him.'
The ugly hippopotami
Observe the leopard leaping by,
And whisper, 'How that hideous cuss
Must envy lovely brutes like us!'
The tortoise is inclined to think

That he's more graceful than the mink;
The tall and angular giraffe
At clinker-built gazelles to laugh;
The whale to murmur with a smile,
'I've got that sailfish licked a mile,
And all the creatures in the sea
Both big and little envy me!
A goodly thing is self-conceit;
It makes mundane existence sweet.
We all, at its benign behests,
Throw proudly out our little chests
Without the magic gift of pride
Nobody would be satisfied."

PREVENTION OF PANICS

The extensive stalling of subway trains on August ninth and the creditable self-control of the passengers are the subjects of the following editorial in the *New York Sun* of August 10:

"Panic is an ever-present danger in such accidents as that which filled part of the East Side subway with smoke yesterday; and on several occasions when comparable conditions have existed, grave injuries have been caused to passengers struggling to escape. All the elements conducive to panic were present in the trains stalled in this latest interruption of traffic, but cool heads controlled and calm was maintained. In one train President Hedley of the railroad helped. He

says that other company employees would have done as much as he did, so complete is their training. In another Mr. Tunney, who learned with the Marines and in the ring how to keep his head, assumed leadership. Trainmen, policemen, firemen and others with the gift of enforcing discipline kept order, and the worst possibilities of the affair did not develop.

"The operation of the subways is so dependable and interruptions of service are so few that their patrons have no particular reason to school themselves in how to act in an emergency. This makes more creditable the composure that saved scores from injury in the tieup on Tuesday."

BOOK REVIEWS

THE 'MUNICIPAL DOCTOR' SYSTEM IN RURAL SASKATCHEWAN By C RUFUS ROREN Ph.D., CPA Octavo of 84 pages Chicago, The University of Chicago Press, [c 1931] Paper, \$1.00 (Publications of the Committee on the Costs of Medical Care No 11)

The hardships of transportation over large areas of territory, the inadequate facilities for laboratory exactness in diagnosis, for hospital treatment and study, the difficulties under which some surgical and obstetric procedures must be conducted, the remoteness from medical associates, and the lack of financial living compensation have, with other reasons, diminished the numbers of doctors in certain rural districts and deprives those people of sufficient medical care. Many plans have been suggested for the correction of this situation. The Committee on the Costs of Medical Care has made a study of the 'Municipal Doctor' in Rural Saskatchewan and an abstract of the report of that study is published in this pamphlet. Each of the municipalities in that Canadian Province is about 18 square miles in territory, with an agricultural population of 505 families or about 1800 people, requiring medical service. The head of each family is usually the owner of a farm of about 400 acres in size. Twenty of the municipalities employ full time doctors while others make grants of \$1500 or less as inducement to physicians to remain there and as exchange for public health services.

As a rule the municipal doctor renders free service to all the tax payers and their families. In some districts there is an extra fee for the first visit such as \$2.00 for the first home visit, \$5.00 for reduction of a fracture and \$7.00 for obstetrical service. All office visits are free.

The municipal doctor is also the health officer of the Community, whose duties include sanitary inspection, immunizations and health examinations. In addition, each physician receives from 1000 to 1500 office visits annually, makes 300 to 500 home calls and in making these according to one physician travels 5580 miles by automobile.

The median salary of twenty municipal doctors on a full time basis was said to be \$4000 while medical expenses amounted to \$731.87.

There is no provision for public laboratory facilities unless one includes the services given to those patients in the hospitals.

Most of the towns and municipalities have other physicians who admit that this system of the Rural Municipal Doctor has greatly reduced their practices and their incomes.

How pleased the doctors are with this arrangement how much public health and preventive work is secured for its community, how valuable is the surety to a community of a doctor resident there even though his work must be limited to that of good general practice exclusive of unusual specialist work, how inexpensive (\$425 per person per year) it all is with many more details the reader will find in a well merited perusal of this report.

T A McGoDRICK

A SURVEY OF THE MEDICAL FACILITIES OF THE CITY OF PHILADELPHIA 1929 Being in Part a Digest of the 'Philadelphia Hospital and Health Survey 1929' By NATHAN SINAI DPH and ALDEN B MILLS Octavo of 298 pages Chicago The University of Chi-

cago Press, [c 1931] Paper, \$1.50 (Publications of the Committee on the Costs of Medical Care No 9)

The abstract of this survey, being in part a digest of a previous Philadelphia Hospital and Health Survey of 1929, is presented by the Committee on the costs of Medical Care as an example of the medical facilities of a large American city. It is offered with the limitations that are implied in such surveys. Groups of practitioners are selected by lot and information sought by questionnaire or personal interview. Of the 3813 physicians in the city in 1929, returns were made by 449. In 1928 returns were made by 245 physicians. Dentists, Osteopaths, Chiropractors and other practitioners' reported in similar proportion.

Notwithstanding these limitations, much information was obtained which will find its proper value in the composition of the Committee's final report.

The net income of physicians was 60% of their gross. The median net income of general practitioners was \$3197 for partial specialists \$4428 and complete specialists \$5500. Of the total amount spent by residents of Philadelphia for prevention of illness and care of the sick, physicians received 26%.

Osteopaths in Pennsylvania are permitted to practice minor surgery as a part of osteopathy and after special training and examination may practice major surgery. 42% of them include in their work obstetrics and 38%, the treatment of venereal diseases. The average net in come of the osteopath is given at \$3724.

There is nothing "slow" shown in the numbers treated in the dispensaries of Philadelphia. In the year before the depression a half million people made a grand total of 2,127,000 visits. Over a million dollars was estimated to have been spent for patent medicines.

The amount of total expenditure in the City (1928) for medical care is estimated at \$103,759,700, or a per capita cost of \$53.89.

Much more information is given of hospital facilities for acute and chronic cases preventive measures, the use of drug stores and patent medicines that will interest and repay the reader.

T A McGoDRICK

A SURVEY OF THE MEDICAL FACILITIES OF THE STATE OF VERMONT By ALLON PFEILES, Ph.D. Octavo of 321 pages Chicago, The University of Chicago Press [c 1932] Paper, \$1.50 (Publications of the Committee on the Costs of Medical Care No 13)

This book presents first a study of the geographical and topographical features and the climate of Vermont in relation to the performance of health and medical care. It presents an extended tabulation of physicians, dentists, nurses as well as those who are classed as other practitioners. The institutions for hospital care and an analysis of pharmacy merchandising are included.

A considerable part of the book is devoted to facilities, activities and finances of public health, in which many interesting statements appear.

Following the general state wide survey, appears a more detailed study of Franklin and Orange Counties. In these surveys the general scheme of investigation of the Medical Survey Committee has been followed, with the usual tabulations and comparisons between urban and rural life in relation to medical care.

T F FILLIOTT

OUR NEIGHBORS

REPORTS OF OFFICERS IN WISCONSIN

The August issue of the Wisconsin Medical Journal contains fifteen pages of reports of the officers and committees of the State Society to be presented to the House of Delegates at the annual meeting on September 17. The introduction by the Secretary calls attention to three features in the conduct of the business:

1. Four Reference Committees will be appointed: 1, Credentials; 2, Resolutions; 3, Reports of Officers; and 4, Reports of Standing Committees.

2. Alternates shall have the privilege of the floor except that of voting when the delegate is present.

3. A member not a delegate or alternate may address the House if he arranges with the presiding officer for a time of speaking.

Library Service—The Secretary reports on library service as follows:

"An annual appropriation of \$500 a year from the State Emergency Board which appears to be sufficient, with the generous aid of Dean Bardeen, to tide over the Medical Library Service until further appropriations may be secured from the 1933 legislature. (The Governor vetoed the usual legislative appropriation of \$5,000.) It is to be noted that while a similar department of the American Medical Association filled 2,450 requests throughout the nation during 1931, in Wisconsin this service established at the University at the instance of your Society filled upwards of 4,425 requests in the same year. Letters continue to be received from members in almost every county in the state commending the work, urging its development and stating that it is one of the most valuable contributions of the Society and University in the field of scientific work. The Medical School deserves our hearty commendation for its willingness to assume the very considerable effort and financial burden that alone has made of this department such a valuable service to our membership. Any similar service on a commercial basis would equal the cost of membership dues."

Legal Services—The Secretary comments on legal services as follows:

"Of the foremost importance in this field is the Summary of Poor Relief Laws Affecting Care of the Indigent Sick. This 16 page leaflet was designed to meet a condition that had hampered physicians in every part of the State from securing a proper or speedy relief of the indigent sick to whom they were called to render service.

"For several years it has been the policy of your Society to provide legal information to mem-

bers where the question presented could be said to be of interest and value to all members as relates to the practice of medicine. During the year many of these opinions have been published in the Journal and include many questions relating to poor relief, use of title 'Doctor', fees of an assistant surgeon, liability of third party for costs of medical service, statute of limitations with respect to malpractice action brought by a minor, liability of nurse as assistant to physician, liability for overt acts of a nurse in industry, liability for overdose, fees for expert testimony, practices under Workmen's Compensation Act, expulsion of member, several relating to the corporate practice of medicine and others of like nature. The files on these opinions rendered in past years are becoming exceedingly useful and increasingly of value.

"Under this title may also be mentioned the studies made through this office with respect to collection agencies. A large information file has been accumulated and two warnings were sent each member during the year with respect to the deceptive contracts of many of these agencies. The Society will analyze any contract of this nature and give an immediate report on its nature and, in so far as possible, on the standing of the agency itself. Nearly a hundred members have taken advantage of this service during the year and the warnings have undoubtedly saved other members considerable amounts of money.

"Upon approval of legal counsel, warnings were also issued to the general membership and society officers on the questionable practices of some insurance carriers in their efforts to secure agreements from members to reduce fees for compensation cases to an entirely unwarranted extent by misleading statements."

Letters to Licentiates—"For several years your Secretary has pursued the policy of addressing a personal letter to each new licentiate in this state. This letter contains our welcome, an expression of our desire to have him as a guest at the next meeting of the county society within whose jurisdiction he will reside, an application blank for membership, and our offer to be of every possible service in assisting him to select his location for Wisconsin practice. We have been of the opinion that this was a service not only to the licentiate but to the members as well."

Public Policy—The report of the Committee on Public Policy is confined to legislation, and enumerates a number of bills in which the Society is interested.

Public Instruction—The Committee on Health and Public Instruction reported on its three major forms of popular medical instruction:

"Under the auspices of the Society, (250) Two hundred and fifty subscriptions to Hygeia each accompanied by a personal letter to the recipient from the Secretary were presented a Christmas time. The recipients included all members of the legislature, state officers including members of the Industrial Commission, Justice of the Supreme Court, and others having to do with questions involving health and the medical profession, libraries of the seven teachers colleges the circuit judges and district attorneys, interested newspaper editors and a selected group of laymen who have long evidenced their interest in public health advance."

"The Society is now broadcasting twice weekly over Station WHA of the University of Wisconsin, and this material is advanced to health officers for rebroadcast over the state station at Stevens Point and the station at Sheboygan. One broadcast each week is of five minutes' duration while the other is a ten minute period."

"The press service of this Society has issued forty-four weekly releases during the nine months since the last annual meeting. These releases are used regularly by a large proportion of the weekly and daily papers of the state and from time to time by almost all of the rest of the press. We are convinced of the worthiness of this effort. It carries to thousands upon thousands of reader articles from authoritative sources advising the public of that which should be common knowledge in the field of the prevention and relief of disease by scientific medicine. For the information of the members, we have printed these releases in each issue of our Medical Journal. Here indeed is an instance of a joint service to public and profession that is worthy of every dollar of the appropriation made available for this purpose."

The list of subjects covered in the broadcasting and press relief services fill over a page of the Journal.

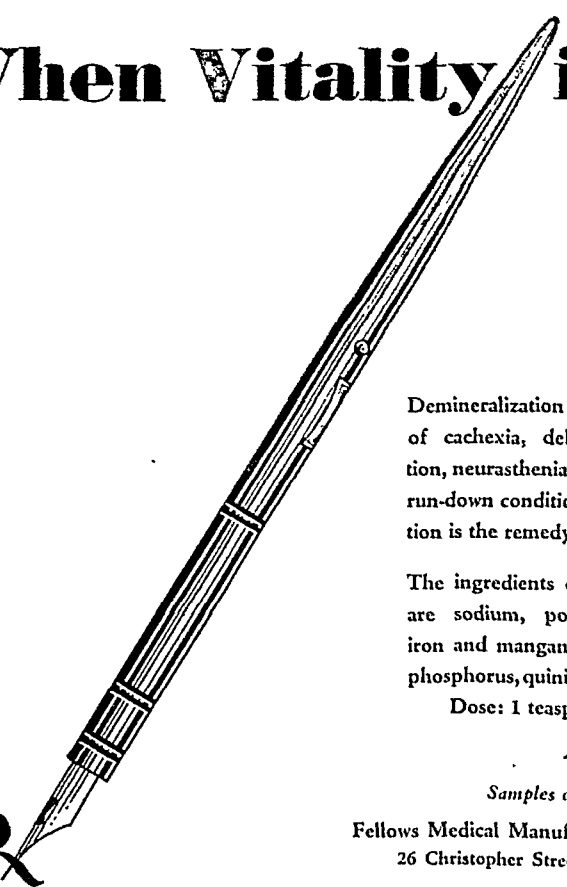

CHARGES IN PUBLIC HOSPITALS OF CALIFORNIA

What patients to treat free in government hospitals is a troublesome problem in every State. The July issue of *California and Western Medicine* tells how the problem was met in San Bernardino County, which has a population of about 150,000 and is located in the center of California east of Los Angeles. The article says:

"The practice of admitting part-pay patients to the County Hospital has been in the past a source of irritation to the medical profession, but

(Continued from page 1038—adv. xvi)

due to the political aspects, seemed difficult to correct. When the taxpayers became aroused this winter and began looking about for ways to cut expenditures, it seemed an opportune time to the medical society to attempt a correction of this abuse, particularly as it could easily be shown where considerable money could be saved the taxpayers.

"It was suggested to and accepted by the Board of Supervisors that the medical society should appoint a medical advisory board, one member from each supervisorial district, who should act in conjunction with the board. No patient other than emergency should be admitted to the County Hospital who did not have a letter from his family physician or the member of the Advisory Board from that district recommending admission. In addition, the patient should be interviewed at the County Hospital by a representative of the County Welfare Commission and should sign a statement setting forth in detail his financial status as well as the age and occupation of those dependent upon him. This procedure rather effectually weeds out those not entitled to treatment. An added check is made by having the hospital mail each member of the Medical Advisory Board a daily list and a summarized monthly list of all new admissions, giving name and address of the patient and name of the doctor recommending admission.

"If a patient is found able to pay something toward hospitalization, that patient is referred back to the medical advisor of his district and the advisor endeavors to find some way of having the patient cared for in a private hospital of his district by getting reduced rates at the hospital, or even getting the benefit of some hospital aid fund if the patient seems worthy.

"Since this regime has been in effect, the population of the County Hospital has been very materially reduced, both in in-patients and in the out-patient clinic; and an estimated saving to the taxpayers of about 26 per cent for the coming fiscal year is assured. This is not entirely by reduction of expected number of patients, it is only fair to state, but also by other economies, which have been suggested in good part by the Medical Advisory Board.

"It is our hope that when the present County Hospital reaches its capacity we can induce the supervisors to subsidize the existing private hospitals for the care of the county cases up to the actual cost per day for the patient if he were to be taken to the County Hospital. We believe this plan has many advantages if properly safeguarded.

"Another accomplishment of this board has been the change of name of the San Bernardino

(Continued on page 1042—adv. xx)

COLDS ARE! COMING!

Soon the fading of the year will bring its annual problem of colds, influenza and rheumatic conditions. The physician's best weapon for fighting these is the natural salicylates, now greatly improved by the addition of a balanced alkali in

ALYCIN

Alycin offers a preferred medication for the treatment of the common cold, because not only does it supply the effect of the natural salicylates, but it also assures the associated alkalization which is so strongly recommended in the treatment of colds and similar conditions • The salicylate in Alycin is Merrell's Natural Salicylate, produced by us under direct control from forest to pharmacy • We invite you to make a clinical test of it.

BUILDS FOR THE YEARS AHEAD

(Continued from page 1040—adv. xviii)

County Hospital to that of the San Bernardino County Charity Hospital. Many citizens felt that inasmuch as this was a County Hospital supported by tax money and the resident medical staff was paid by the taxpayer, he the taxpayer, was entitled to free treatment there. The change of the name brought it rather forcibly to their attention that they are paying for care of the county charity cases only.

"Previously all county employees were entitled to free hospitalization, whether indigent or not. This rule has been rescinded and employees are now on the same basis as all other residents except for industrial accident cases among employees of the county, which are still cared for free.

"The only part-pay patients received at the County Hospital now are those suffering from the contagious diseases which are not accepted by the private hospitals of the county. Some of these are able to pay for their care in whole or in part, and are expected to do so.

"The County Medical Society has been fortunate in having a very conscientious and public-spirited Medical Advisory Board, which has labored long and hard on this problem. The board has the full support of the medical society and the confidence of the Board of Supervisors and the Tax Coordinating Committee, and because of this has been able to accomplish much."

ETHICS OF MAKERS OF ARTIFICIAL LIMBS IN MISSOURI

The August Journal of the Missouri State Medical Association records the action of the House of Delegates in approving a code of ethics adopted by the makers of artificial limbs. The Journal says editorially:

"The Association of Limb Manufacturers was organized in 1917 at the urgent request of the Department of the United States Army and the Department of the United States Navy. Its purposes are wholly educational and ethical. One of its principal purposes is to elevate the industry to the plane of dignity and importance which it deserves and to prevent and punish fraudulent and unbusinesslike conduct on the part of any one claiming to be a limb maker."

The code of ethics of the limb manufacturers follows:

"CODE OF ETHICS"

"Section 1. I will not make any untruthful statements about a competitor, a competitor's make of artificial limbs, his financial standing, the personality, morality or honesty of competitors or members of a competitor's firm, whether

by word of mouth, writing or printing, or by commendatory letters or deceptive pictures, or by exhibiting or causing to be exhibited alleged samples of a competitor's manufacture.

"Sec. 2. I will not accept an order for an artificial limb by agreeing to credit the payment of a deposit already made to another manufacturer or discount the amount of the deposit paid to another manufacturer from the price of a limb. I will not endeavor either directly or indirectly to cause a person who has already placed a bona fide order for an artificial limb with another manufacturer to cancel such order.

"Sec. 3. I will not furnish or agree to furnish an artificial limb complete or incomplete, to anyone without a bona fide order.

"Sec. 4. I will use every effort to furnish my customers satisfactory artificial limbs and will in all cases of dispute protect my customer's interests to the extent of using every honest endeavor to furnish a properly made artificial limb. Should there be any changes needed at time of trial of a new limb, I will make them, and should occasion demand, I will agree to make another fitting to

the end that the customer shall be furnished an artificial limb that is properly constructed and correctly fitted.

"Sec. 5. I will not, directly or indirectly, interfere with or entice an employee to leave the employ of any other member of this Association. I will use every honorable means to help a member of this Association to acquire and maintain the services of expert workmen.

"Sec. 6. I will not use my membership in this Association for the purpose of advertising or advancing my own business interests to the injury or detriment of any other member. I will not solicit orders for artificial limbs by making promises that are impossible of fulfillment.

"In but few cases is the work of the physician or surgeon left to others to complete. The making and fitting of an artificial limb, however, must be delegated to the experts in this industry. It is therefore gratifying to know that the manufacturers of artificial limbs have voluntarily adopted rules of conduct that will go far toward protecting the purchaser and wearer of the limb from fraudulent, dishonest and incompetent limb makers."

(Continued from page 1044—adv. xxii)

in our opinion, one of the finest and most progressive steps any medical society has taken in recent years.

"In the matter of attendance, previous records were broken; the registration figures showing 525 members present.

"The scientific program met our expectations in full, and we shall from that source acquire approximately sixty original articles for publication in the Journal."

FINANCES OF GEORGIA ASSOCIATION

The April number of the Journal of the Medical Association of Georgia contains a chart showing the percentage of income and expenses allotted to their source. The following tables gives the same figures:

"The income of the Association, from all sources, is as follows:

"1. Dues—67.22 per cent.

"(a) Dues for general expenses—38.41 per cent.

"(b) Dues allotted as subscriptions to the Journal—28.81 per cent.

"2. Advertising—28.16 per cent.

"3. Commercial exhibits during annual sessions—4.46 per cent.

"4. Miscellaneous subscriptions—0.16 per cent."

"The disbursements of Association for all purposes are as follows:

"1. Journal—46.59 per cent.

"(a) Printing and mailing—30.21 per cent.

"(b) Salaries—12.11 per cent.

"(c) Postage—1.39 per cent.

"(d) Rent—0.80 per cent.

"(e) Engraving, stationery and reprints—2.08 per cent.

"2. Committees, Council and delegates to A.M.A. 20.48 per cent.

"(a) Medical Defense—10.13 per cent.

"(b) Council—1.03 per cent.

"(c) Public Policy and Legislation—2.03 per cent.

"(d) Presidents—3.56 per cent.

"(e) Delegates to A.M.A.—3.73 per cent.

"3. Annual session—7.09 per cent.

"(a) Reporting—2.91 per cent.

"(b) Invited guests—0.98 per cent.

"(c) Scientific and commercial exhibits—1.86 per cent.

"(d) All other expenses—1.34 per cent.

"4. Salaries—12.11 per cent.

"5. All other expenses—7.43 per cent.

"6. Reserve—6.31 per cent."

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min.
GUAIACOL	1 min.
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve Bronchitis—acute or chronic. It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

DIPHThERIA ANTITOXIN (Lilly)

Diphtheria is an insidious disease that, despite the progress of medical science which has provided both successful treatment and highly satisfactory preventive measures, takes a needless toll of child life every year.

Today every physician knows the virtue of Diphtheria Antitoxin promptly administered, and is equally familiar

with the immunizing properties of both Toxoid and Toxin-Antitoxin Mixture. The problem before the medical profession, therefore, is to stimulate thought and action on the part of school authorities and parents in order that diphtheria may be entirely eradicated—as it can be, theoretically at least, with the earnest support and co-operation of all concerned.

Diphtheria Antitoxin, Lilly, is said to be an unusually fine product of small volume, low total solids, and sparkling clarity, free from non-essential proteins. Diphtheria Toxoid and Toxin-Antitoxin Mixture, Lilly, bear an excellent reputation and are said to be preferred for active immunization by a growing number of physicians. Toxoid is said to be favored by many in immunizing the younger age group. See page xiv.—*Adv.*

HOSPITAL RECEIVES FUNDS

The New York Post-Graduate Medical School and Hospital has been made benefactor of several grants during the month of July, according to Dr. Edward H. Hume, Executive Vice-President of the Institution. They are: a grant of \$1,000.00 from the Josiah Macy, Jr., Foundation, for the study of cholesterol metabolism in relation to arteriosclerosis; an anonymous gift of \$2,000.00 toward current expenses; a gift of \$7,500.00 from Mr. Allen Wardwell toward the current expenses of Reconstruction Unit, which has also received \$2,000.00 from the legacy of Mrs. Roger B. Williams. The final payment of a legacy, totalling \$25,000.00, left by Julia Seligman in 1922, has been made to Post-Graduate. This money has been used for philanthropic and research purposes in the eye clinic.—See page xxix.—*Adv.*

COURSE OF FRACTURE TREATMENT 1932

Ten Clinic Lecture Demonstrations

given by
The New York and Brooklyn
Regional Fracture Committee
of the
American College of Surgeons

A concentrated course embracing the practical application of modern methods of fracture treatment—from October 31 to November 5 inclusive.

Clinics will be given at the following hospitals:

Presbyterian, Harlem, Beekman, Bellevue, Roosevelt, Ruptured and Crippled, Long Island City and Cumberland Street.

Attendance is limited. \$25 is charged for the course.

SYMPTOMLESS HYDRONEPHROSIS REVEALED BY TRAUMA A REPORT OF THREE CASES*

By GEORGE E. SLOTKIN, M.D., BUFFALO, N. Y.

MARKED hydronephrotic degeneration of a kidney may take place, persist for years without creating any untoward symptoms, until an injury aggravates and reveals the existing condition. This important finding was emphasized by three cases recently seen in which the injury in itself was of no great importance, but was sufficient, however, to create symptoms calling for a complete urological examination and, at this time, it was discovered that in each case there was present a pathological kidney with changes which had taken a long time to develop.

One must be impressed by the lack of symptoms in a kidney which has been obstructed to such a degree as to cause its degeneration into a large hydronephrotic sac, and yet remain undiscovered until some unrelated condition arises to reveal the persistence of the symptoms established at the time of the accident.

The importance of thorough investigation of any complaints of the patient following an accident, and the diagnosis of these ailments, is also of paramount importance from a medical-legal standpoint. If it can be established that an injury is not a direct cause of the patient's complaints, or that a pre-existing condition has been aggravated by this injury rather than directly caused by it, then again the importance of establishing these important facts is emphasized. In none of the cases related were there any complaints whatsoever previous to the time the injury was sustained. The patients enjoyed the best of health and had had no cause to seek medical advice for years, and yet the findings and changes in the kidneys are of such magnitude as to warrant their description and report. None of the classic symptoms of a hydronephrosis, to wit: presence of tumor, drag-

ging sensation in the side, pain, or hematuria, had been manifested by the patient at any time up to the day of the injury sustained. Ames and Delord¹ make a report of such a case and 18 similar cases on record.

Case report No. 1. Patient was a white male, age 34, seen July 16, 1930, weighing 240 pounds, who was referred because he complains that three days previously, while working in an ice house lifting cakes of ice on the carrier, slipped on the floor and did a "spread eagle," and immediately developed burning on urination, hematuria and frequency. Patient went home to bed, after 24 hours the hematuria stopped, but the frequency of every half hour and nocturia 3 to 4 times a night has persisted. Patient claims that he has always been in the best of health and, aside from an infection of gonorrhea 15 years ago (which persisted for two months and was apparently cured), has had no illness or complaints.

An examination discloses an unusually developed, white male, not acutely ill. General physical examination is essentially negative. The abdomen was soft, not extremely obese, musculature unusually developed. There were no masses seen or felt. Palpation of both kidneys, by deep pressure, elicited no pain. Palpation over the bladder causes some pain. Examination of the prostate, seminal vesicles and scrotal contents were negative. Wassermann negative. Urinalysis: voided specimen shows it to be cloudy in appearance, specific gravity 1024, one plus albumen, no sugar. Microscopically: no casts, a few epithelial cells and loaded with pus cells, from 50-75 per low power field.

A flat x-ray of the KUB was made. The left kidney shadow was normal in size, shape and position, with no evidence of stone. The

* From Central Park Clin. c.

¹ Ames and Delord. Hydronephrosis revealed by trauma. *J. Urol. & Par.* 1919 vol 285. Abs. *J. Am. M. Ass.* Chicago 1919.

right kidney could not be determined, but there was no evidence of stone.

Cystoscopy July 16, 1930. The cystoscope entered the bladder without any obstruction. The bladder was normal except for the right orifice. There is present a rather large ureterocele, with a bulging and prolapse of the ureter. The left kidney was easily catheterized, but the right cannot be determined. The left kidney urine is perfectly clear, grossly and microscopically. Intravenous indigo carmine was injected to facilitate the finding of the right orifice. The dye returned within normal limits with good intensity through the left catheter, but visualization of the right side showed no excretion of dye after 25 minutes.

As this was a Compensation Case, a report was made of the findings and instruction that further examination would be required to determine the amount of pathology on the right side. Nothing was heard from this patient, or the Company, until October 19, 1930.

The patient was cystoscoped again and the same pathology noted, i.e., prolapsed bulging right ureter, with complete obscuration of the orifice. At this time, intravenous Uroselect-

ceau catheter was inserted through the orifice to the kidney without any obstruction, and it was noted that there was a continuous flow of pale urine. Intravenous indigo carmine was immediately given with the bladder still open, and no dye appeared for 15 minutes from the right side. The bladder was then closed around a Pezzar catheter and the patient returned to his bed in good condition. An uneventful recovery was made.

On the 7th day after the operation, the patient began to complain of pain in the right upper quadrant. On the 17th of December, the right kidney was approached through a right lumbar incision. It was easily identi-

FIGURE 2
Case 1. Cut Section Interior.

FIGURE 1
Case 1. External Appearance.

tan injection was made and the left kidney pelvis showed normal outline, as did also the ureter. But the dye in the right kidney was rather obscure and faint. It was felt that the right ureterocele was too extensive to attempt to reduce by cystoscopic manipulation. Therefore, a cystotomy was performed on October 20th and the very large ureterocele of the right ureter noted, the orifice found with some difficulty under the folds of the prolapse. This was thoroughly slit up with a scissors in the orifice, resulting in an immediate gush of very pale urine, and complete reduction of the ureterocele. A large Gar-

fied and was found to be about five times the normal size, soft and putty-like, with no semblance of firm renal tissue. There were a great number of adhesions between the fatty capsule and the kidney proper, so that the kidney was not delivered with ease. It was finally stripped free, however, and delivered into the wound.

In looking for the ureter, there suddenly presented itself in the wound, a large twisted mass of tissue which resembled gut. It was about 3 centimeters in width and resembled colon. This was stripped free and followed up to the pelvis where it was noted that it curled in behind the lower pole of the kidney. There were several vessels, rather large and aberrant in character, crossing this loop just at its entrance apparently into the kidney. The entire mass was dissected free, the vessels tied and suddenly another loop, similar to the above, presented itself higher up and attached in a similar way to the pelvis, with fairly large vessels crossing. This loop was the same size as the former. Both were dissected downward but no connection was found between the two. A trocar was inserted into the kidney and a large amount of fluid evacuated. Immediately upon this evacuation, it was noted that the loops collapsed and milking these ureters "as we now discovered them to be," caused an exudate of

more urine through the trocar. Both of these ureters were ligated low and the kidney removed. Pathological report follows.

The material as received, consists of a kidney bisected through the middle. There are two distinct ureters and pelves. These are both markedly thickened, enlarged, and distended into the kidney so as to leave only the rim of renal parenchyma, one part is 1 mm. in thickness, while in other situations it is 3 and 4 mms. thick. In these thicker portions, we find circumscribed areas with destruction of renal parenchyma. The kidney externally measures about $13\frac{1}{2}$ centimeters in long diameter, and 5 centimeters in thickness. On stripping the capsule, we find the external surface exhibiting nodular elevations with intervening scarred contraction (Fig. 1 and 2).

The patient was amply drained and had no post-operative complications. He left the hospital on the 14th day with the wound healed by first intention.

Case report No. 2. Patient was seen on consultation on November 18, 1930, in the hospital, complaining of severe backache, pain in the left upper quadrant and bloody urine. Six days previous, the patient was in an automobile accident, a car colliding with his, and causing sufficient shaking up so that he "wrenched his back." Was taken home and treated by his family physician for two days with no improvement of his symptoms. On the fourth day, noticed that he was passing blood in his urine each time he voided. The pain in the back had become more severe and now extended from around the back over the ribs, down the left side to the iliac region. Patient voids once in four hours and about once a night. He never had any previous symptoms, has always been in excellent health, is a chemical engineer by occupation and was able to stand for hours at a laboratory table without any fatigue.

When the patient was seen at the hospital, November 18th, he did not appear acutely ill, temperature and pulse normal, but was still passing free blood in the urine with each voiding and complained of the constant pain the left upper quadrant.

Physical examination shows a rather slender but well developed adult male, 30 years old, who gives an intelligent history of his complaints and is emphatic in stating that previous to the time of the accident, he had always enjoyed the best of health. All physical examinations are essentially negative. The abdomen is flat, soft, no evidence of injury or masses noted. Palpation shows the entire abdomen to be soft except in the left costo-vertebral angle and left upper quadrant over the kidney, the patient is extremely tender and a definite mass can be felt on deep palpation, which aggravates the pain

which the patient complains of. It was believed that the patient was suffering from a ruptured kidney, or more or less moderate degree. A flat plate of the K.U.B. tract on the 19th, shows both kidneys to be rather large, particularly the left. No x-ray evidence of stone and no evidence of any bony fracture noted. The next day, November 20th, he was cystoscoped.

The bladder urine was definitely bloody. The bladder itself was normal in all respects. Left ureteral orifice was easily entered with a No. 6 catheter full length to the kidney pelvis. There was an immediate gush of bloody urine which appeared as if it had been undergoing some decomposition. Right kidney was easily catheterized, the urine was clear and normal in flow.

FIGURE 3.
Case 2

About four ounces of bloody urine was drained off the left kidney pelvis with immediate relief noted by the patient. Indigo carmine was injected intravenously and appeared in five minutes on the right side with good concentration, 10 minutes on the left with only fair concentration. Sodium iodide was injected into the left kidney pelvis to determine if the renal capsule had been broken in the injury, or to note the displacement of sodium iodide solution into the kidney proper. Ten cc. was injected with no complaint by the patient and a pyelogram was made. The right ureteral catheter slipped down so that in an attempt to make a right pyelogram, no result was obtained. The x-ray findings of the left pyelogram are noted (Fig. 2). The pelvis is not visu-

alized, the media having flowed into two irregularly shaped pockets and there been diluted with resulting loss in contrast and definition. Findings are compatible with ruptured kidney.

The patient was treated expectantly, all symptoms gradually subsided, the hematuria disappearing within three days and, on December 1st, the patient was discharged, feeling well, with no hematuria but a voided specimen shows a rather large amount of pus cells in the urine. On December 3d, patient was cystoscoped in the office because of the persistence of pus cells, and a No. 9 Garceau catheter was inserted into the left kidney without any obstruction. There was a rapid flow of pale urine under tension. Intravenous indigo carmine, at this time, showed no return

FIGURE 4.
Case 3.

after 20 minutes. At this time, it was felt that a permanently damaged kidney was present. On December 12th, under spinal anesthesia, the left kidney was exposed through a left oblique incision and muscle splitting approach. The kidney was found to be large, tense, firmly adherent at its upper pole and rather difficult to deliver. It was about three times the normal size. The fatty capsule was adherent throughout. The ureter was small and separately tied. The pedicle was long and easily disposed of. The patient was drained and, on December 30th, was discharged from the hospital feeling well and the wound healed by first intention. From then on, the patient gained rapidly in weight, the urine

cleared up and he has been improving steadily ever since.

Pathological report: This kidney is about three times its normal size and is surrounded by fat and fibrous tissue which shows evidence of chronic inflammation.

On section, the pelvis is found to be enormously dilated with obliteration of most of the kidney substance, the whole of the kidney forming a multilocular sac with small areas of kidney substance at the periphery.

Sections taken through various portions of this kidney were stained and examined. They showed thickened capsule with some fibrous and a few sclerotic glomeruli in the cortical portions of the kidney. The kidney substance here found seems to be in a very fair condition. Towards the pelvis, there is marked fibrosis and evidence of chronic inflammation with cavity formation, granulation tissue and pigmentation of the cells.

This case shows this kidney also to be that of an old hydronephrotic kidney, symptomless until the time of the accident.

Case report No. 3. Patient is a white male, 35 years old, married and has four children, occupation butcher. He had gonorrhea 15 years ago, which lasted three months but from which he had never had any complications or recurrence. Aside from the above, he has never had any urologic complaints. In July, 1930, he noticed that a mass was forming in the upper right quadrant, over the costal margin. States that this came on directly after lifting a very "heavy side" of beef. Has had no particular discomfort from this mass and has worked every day without any urinary disturbance or other urological complaints until September, 1930. On the 8th day of September, the patient fell 18 feet down an elevator shaft, was sent to the hospital where he was treated for a fractured skull and a fractured little finger of the left hand. Since September, the swelling which he had in the right upper quadrant, has grown steadily worse and, after he recovered from his fractures, he noticed that upon walking there would be a dragging sensation in the right side. At no time did the patient have any urinary disturbance. The patient was examined at the hospital and, because of the peculiar attachment and shape of the mass, it was originally diagnosed as a hematoma of the liver or liver cyst.

Physical examination of the upper body is negative. Abdomen is scaphoid, seems full in upper right quadrant which has an irregular surface and moves with respiration, so that the hand can be inserted between it and the costal margin. This is likely a combination between kidney and liver.

Blood chemistry and function tests are all normal. In order to determine the condition present, by exclusion, a series of x-rays were made which

showed the ill defined mass filling the entire right side of the abdomen, a G I series disclosing the ascending colon displaced toward the midline by the mass. To exclude the possibility of a kidney involvement, it was then suggested that a cystoscopic examination be made, which was performed on May 28, 1931.

Cystoscopic Findings The cystoscope readily entered the bladder, the capacity and interior of which were normal. The orifices were clean, and a No. 6 catheter easily entered the left kidney without obstruction. A No. 6 catheter passed up the right ureter for 20 centimeters when it became impeded. The flow of urine from the left kidney was normal and regular and clear in appearance. The flow from the right kidney was immediately rapid, the urine gushing from the catheter in a steady stream, denoting fluid under pressure. Six ounces was obtained and then 750 cc was removed by suction syringe. An intravenous injection of indigo carmine appeared from the left kidney in $4\frac{1}{2}$ minutes with good intensity. No dye was excreted from the right kidney for 20 minutes. At this point, the patient remarked that the pressure and pain which he had been complaining of in his right side, was relieved "as if a weight had been taken off his abdomen," and upon palpation, the mass which had previously been felt, was considerably smaller. An x-ray was made and 90 cc sodium iodide was injected into the right kidney and a series of pyelograms made.

These pictures show a distinct hydronephrotic sac of extreme size, with complete destruction of the kidney, which can be seen at the back of the hydronephrotic sac with a few dilated calices

(Fig. 3). The catheter was allowed to remain in situ for an hour to drain off the fluid.

In view of the above findings, a definite diagnosis of a large hydronephrosis of the pelvis of the kidney was made, which was non-infected as subsequent cultures determined.

On June 11th, under spinal anesthesia, I operated this patient through a right lumbar incision. The kidney was exposed and it was found to be attached to the under surface of the peritoneum and the diaphragm above. The excision of the sac was made somewhat difficult by this adherence. Finally, a trocar was inserted into the large hydronephrotic mass and 3,300 cc of fluid evacuated, which facilitated shelling out of the mass to a great degree. The patient made an uneventful and uncomplicated convalescence and, on July 11th, was discharged from the hospital in splendid condition with the wound healed and gaining weight. When last seen, on September 17th, the patient was in splendid condition and had gained 13 pounds.

CONCLUSIONS

1 Three cases of unusual hydronephrosis are presented, which pathologically proved to be of long standing.

2 No symptoms were manifested by any of the patients until aggravated by an injury.

3 The injury was not sufficient to cause the amount of damage manifested in the kidneys.

4 Persistence of urinary symptoms after any injury, no matter how trivial, warrants a complete urological examination.

5 A large hydronephrosis may persist for years, symptomless and unrecognized.

CELIAC DISEASE

By A. CLEMENT SILVERMAN, M.D., SYRACUSE, N. Y.

From the Department of Pediatrics, Syracuse University College of Medicine. Read before the Section on Pediatrics at the Annual Meeting of the Medical Society of the State of New York in Syracuse, June 3, 1931.

Introduction

CELIAC disease is treated in pediatric literature as a disease entity. A few American authors include it under the heading of chronic intestinal indigestion. Since it is probably brought on by improper feeding during the second year of life, or rather improper feeding in an infant with some disturbed tolerance, this condition should be better known by general practitioners of Medicine, because its successful treatment is within the province of the family physician.

The name Celiac Disease is derived from the Greek word meaning belly, and was first applied by Samuel Gee in 1888.¹ In his description, Gee pointed out that it is an affection that is particularly apt to occur in children between one and five

years of age. He described it as a diarrhea alba in which emaciation and cachexia occur. The stools are loose, not formed but not watery, more bulky than the food taken would seem to account for, pale in color, frothy and with a stench suggesting putrefaction. He compared the pale loose stool to oatmeal gruel in appearance.

The first American work on this disease was a small monograph in 1908 by Herter² who called the disease Intestinal Infantilism. He makes no reference to previous work. The most recent monographs came out in 1927 by Leindorf and Mautner³ of Vienna, and in 1928 by Fancom⁴ from Feer's clinic in Zurich.

Celiac disease is comparatively rare and occurs more frequently in private than in ward practice. Most of the cases have been reported from Eng-

land, the United States, Switzerland and Germany. The Latin countries seem to be free from this disease. It usually makes its appearance in infants between nine and eighteen months and seems never to occur during the period of breast feeding.

Clinical Picture of the Disease

Celiac disease develops insidiously. The well-developed case shows the following cardinal symptoms:

1. Arrested growth and development.
2. Large abdomen.
3. Large, characteristic stools.
4. Hydrolability and fluctuation of weight.
5. Anemia.
6. Nervous manifestations and personality changes.

1. *Arrested Growth.* The arrested development has led to the characterization of celiac disease as a form of infantilism. A well developed case is invariably very much underweight and usually undersized. There may be a marked lack of subcutaneous fat. The muscles of the buttocks may be almost completely wasted. As a result of the muscle weakness the child may be unable to walk or may tire very easily. The development of the long bones is retarded and x-ray of the bones shows porosis but rarely any rickets.⁵ (Fig. 1)

2. *Large Abdomen.* The large abdomen stands in contrast to the thin chest and spindly arms and legs. The child walks like a woman in late preg-

FIGURE 2

Front and side view of a child with Celiac Disease to show large abdomen.

nancy. The large abdomen is probably due to lack of tone of the abdominal wall and to distention of the intestines with gas. X-ray does not show much dilation of the colon. There is no free fluid in the abdomen and no masses or glands can be felt. (Fig. 2)

3. *Large, Characteristic Stools.* The stools are always very large, light-colored, usually foul smelling. Fermentation and putrefaction may be present at the same time. They usually number two to four a day and are almost always acid in reaction. The stool may be larger than the food intake, and in some instances the stools of the celiac patient have been found to be ten to twenty times as large as the average stool of the normal child. As much as ninety per cent of the ingested fat may be found in the stool in the form of fatty acids, soaps and neutral fats. Frequently undigested starch is found.

4. *Hydrolability and Fluctuation of Weight.* Edema is very common in this disease and may affect almost the whole body. At other times water may be lost so very quickly that loose skin folds are present in the thighs, arms and buttocks. One-tenth of the weight may be lost in 24 hours. Obviously water and salt metabolism is severely disturbed. This condition is probably of the nature of hunger edema.

5. *Anemia.* This is present practically in every case. Usually the anemia is of the secondary type. Rarely, however, it may resemble the primary type.

6. *Nervous Manifestations and Personality Changes.* The child with celiac disease is rest-

FIGURE 1

Photograph from German case records. Patient 2½ yrs. old. Left photograph during illness. Right photograph 2 months later.

less, whining, irritable, morose, never smiling. The child's disposition and personality are changed. When the first improvement comes, the improvement in disposition is the most striking thing. The child begins to smile again and develops a voracious appetite. The mental development is not retarded as a rule. The child may not talk because he does not wish to talk; he will whine continually and point to what he wants rather than ask for it.

Case Histories

The five case histories which follow were observed in my private practice from 1918 to 1929. One of these children is of American Jewish parentage, the others are of Anglo-Saxon derivation. In all of them there were more or less psychoneurotic family tendencies. For each case a chart has been prepared showing actual observations of height and weight in comparison with the expected averages for the age. The narrative for each case has been sketched to tell very briefly what was happening and is to be read in conjunction with the charts. For only two cases are before-and-after pictures available.

Case 1—A.P. Female, birth weight, 6½ pounds; weaned at five months because of vomiting. Early history otherwise negative. First seen by Dr. Philip Potter at age of 16 months, in January, 1917, for swelling of hands and feet, and for pallor and weakness. Weight at that time, 20 pounds in clothes. Stools were clay col-

ored and pasty; abdomen large. Diet contained considerable cereal and crackers.

When first seen by me patient was 2 years and 4 months old and weighed 17 pounds. She was very short, had a large protruding abdomen and was markedly peevish and fretful. A week later edema was again present. There was no starch in the stool but considerable fat was present. Urine was negative.

In March, 1919, at the age of 42 months, she weighed about 20 pounds and showed symptoms of tetany. Personality changes were very pronounced.

CHART 2.
Case 1—A. P.

At four years of age, in September, 1920, after doing well all summer, stools became foamy. The child became less active and she began to show loss of weight and at times edema. At the office she weighed 19½ lbs. A neighbor volunteered the information that she was given crackers and sugar cookies. From this time on she was kept on protein milk and starchy food was eliminated for a time, and she began to improve. (Chart 1).

She was not seen again until six years later and showed considerable improvement in weight and height. She was much shorter than her younger sister but otherwise seemed to be in good health. (Chart 2.)

This case, the first in my series, came under treatment late and an indulgent grandmother did not always cooperate. For a considerable time there was uncertainty about the diagnosis and treatment. This child shows more marked arrest in growth than any of the subsequent patients.

Case 2—V.R. Female. Birth weight 7 pounds. Breast fed nine months and when weaned she weighed 18¼ lbs. First tooth at five months. When put on modified milk, she did not get on well, failed to gain at first and later began to lose weight. Came under care of Dr. Philip Potter who tried her on protein milk but baby refused it. Weight at 2 years dropped to 14¼ lbs. Dr. Potter then used sweetened protein milk which she took and began to gain weight. At 2½ she rose to 21½ lbs. When cow's milk was again

CHART 1.
Case 1—A. P.

CHART 3.
Case 2.—V. R.

given at this time, she lost weight and had to return to the protein milk with other protein foods.

First came under my care in May, 1923, at the age of 33 months. (Chart 3.) She was small, pale, fretful and peevish. She had a large abdomen and some edema. Her stools were large, soft and acid. She was given protein milk, Karo syrup, chicken, scraped beef and within four months gained 4 lbs. From then on she made un-

eventful progress and at the present time she is normally developed.

Case 3—H.A. Male, birth weight 9 pounds. Breast fed for one year. When first seen at 13 months of age he weighed nearly 23 lbs., but had some slight evidence of rickets and slight eczema.

Three months later, at 16 months, he had begun to show pallor, weakness and loss of weight. The stools were large, pale, acid and showed an excess of fat. The abdomen was large and he was markedly irritable. He had been getting large amounts of starchy and sweet foods. Weight was down to 20 lbs. Was put on skimmed milk.

Six weeks later was down to 19½ lbs., loose folds of skin showed on the arms and legs. Another pediatrician who saw the child suspected tuberculosis and advised high fat feedings. On this he lost weight, looked worse and became more irritable. When put on protein milk at 20 months he began to gain, his disposition improved and the stools improved.

At 2½ years he developed some edema and the stool became acid. For nearly 3 months he failed to gain. Again when he was nearly three years old he began to lose weight and it was found that he had been getting ice cream cones, cereals and some plain milk. When his diet was again restricted to protein milk and a high protein intake, he began to improve and went on to past normal weight for his age before his 4th birthday; his height, however, remained below the average (Chart 4). At the present time he is up to average weight and height for his age.

FIGURE 3 (a).

Snapshots of Case 3, H.A., whose weight record is shown in Chart 4. (1) Patient as he appeared at about 1 year of age, before the illness commenced and weighing about 23 pounds.

Fig. 3 shows home-made snapshots of him before he became ill, during the illness and 5 yrs. after recovering.

Case 4—S.E. Female, birth weight 7 lbs.

CHART 4.
Case 3.—H. A.

FIGURE 3 (b)

(2) Same patient at 20 months of age, after illness was well marked and the weight down to about 17½ pounds.

FIGURE 3 (c)

(3) Picture on left at 21 months of age, general condition being about the same as preceding snapshot. Picture on right at 26 months of age, just as the weight curve is beginning to rise. Note expression.

FIGURE 3 (d).

(4) Same patient in March, 1923, about a year after improvement began, and again in the summer of 1924. Notice the prominent abdomen still present in both pictures.

Breast fed 3 mos. and then weaned. First tooth at 10 mos. At 13 mos. weighed 20½ lbs. Diet consisted of 1 qt. of milk, cereal twice daily, egg and vegetable.

At 15 mos. there was noticed marked irritability, enlargement of the abdomen and diarrhea. She passed 7 stools a day which were large, soft, pale and acid. Weight at this time

FIGURE 3 (e).

(5) Same patient in July, 1929, showing normal height and weight and the disappearance of the large abdomen.

19 pounds. Started on protein milk and began to gain rapidly, reaching 22 lbs. by the time she was 18 mos. old. At this time she was getting cottage cheese, buttered toast, coddled egg, scraped beef and gelatine. Somewhat later she again became cranky and irritable without showing loss of weight, although gain rate was slowed considerably. Reduction of starch and fat in her diet resulted in further rapid increases in weight. (Chart 5.)

This case represents a mild course of short duration. It was diagnosed promptly and treated energetically. No stunting of growth resulted.

Case 5—R.C. Male, birth weight 7 lbs. and 2 oz. Breast fed for 11 mos. First tooth at 4 mos. Walked at 14 mos. Said to have had 16 teeth at 20 mos., and to have weighed 26 lbs. This was in October, 1928; 4 mos. later in Feb., 1929, he weighed 22 lbs., 15 oz.

First seen by me on April 22, 1929, at the age of 27 mos., with the history that during fall he had begun to have whitish stools and later diarrhea. His appetite good but "food seemed to pass through him undigested." He began to lose weight and became cranky and irritable. He had been getting bread, crackers, cereal and some meat. Some 2 or 3 months before a pediatrician

FIGURE 4

Picture of case 5, R.C. at the age of 2 years and 2 months, and 5 months later.

had seen him and advised protein milk but the child would not take it. One physician thought he had rickets and gave him a long course of ultra violet treatments. For some time he had been too weak to walk, and when he sat up his spine was curved. He cried a great deal and was very difficult to manage because he was so insistent as to food he would take or refuse to take. For the past week or two he had been very much "bloated" especially in legs and feet.

Examination showed a thin, emaciated baby with cold extremities. He showed marked irritability and was whining constantly. Rectal temperature 97. Head large, face triangular and drawn; anterior fontanel closed; hair light, moderately abundant but rather dry and lifeless. Circumference of head 50.5 cm. Eyes, ears, nose, throat negative. Chest circumference 47.5 cm. Expansion 1 cm. Ribs not beaded. Heart negative, lungs clear. Abdomen distended; liver and spleen not palpable. Highest level of abdomen (lying) 3 cm. cephalad from umbilicus; at this point, abdominal circumference 51 cm. Arms spindly. Marked pitting over tibiae; dorsum of feet markedly swollen and bluish. Skin generally dry and extremely loose. No fat or muscles felt on buttocks. Face and body show considerable tanning and some desquamation. Spine shows kyphosis in lower dorsal region. Lymph nodes are shot-like in groins, axillae and suboccipitally.

Laboratory findings: Urine negative for albumin, sugar and indican. Reaction alkaline.

Stools large, liquid or soft, grayish white, extremely acid. Lugol test positive.

Blood (May 10, 1929) haemoglobin 60; red cells 4,000,000, white count 9,200; polys 44%, lymphocytes 54 per cent, mononuclears 2%. Some variation in size and shape of red cells, large and small forms present but large predominating.

Progress notes:

4-23-29, started on Mead's boilable protein, full

CHART 5.

Case 4.—S. E.

strength, with saccharin added for sweetening. Phenobarbital given for irritability.

4-26-29, much improvement in number and appearance of stools. Edema decreasing.

5-3-29, weight this morning 18 lbs. 10 oz. Skin hangs in folds, legs extremely spindly. Edema appears to be completely gone. Body temperature 96.8 rectal.

5-10-29, weight 16 lbs., 1 oz. Transfusion of 180 cc. of mother's blood.

5-12-29, color and general appearance better. Has slept well last two nights. Apparently improved. Takes 15 oz. protein milk at one feeding.

5-26-29, disposition better. Put on double strength protein milk with addition of cheese, gelatin, meat, mashed and strained carrots and spinach, orange juice, cod liver oil, iron citrate.

CHART 6.

Case 5.—P. C.

At 3 yrs he has continued to do well. Stools are firm, of smooth consistency and number 1 or 2 daily. He takes double strength protein milk and cheese, gelatin and meat. Height and weight records are shown in Chart 6. His appearance at about 2 yrs and again 6 mos later is shown in Figure 4.

Early in 1930 he was able to return to a normal diet and ordinary milk with only an occasional slight digestive upset.

It would be extremely interesting to go into the details of the metabolism of celiac cases and to discuss the probable factors concerned in the pathogenesis of the disease. This, however, would take too much time and it is thoroughly discussed in the recent monographs.^{2,4} It will have to suffice to say merely that the disease is characterized by an inability to utilize fats, starches and more complex sugars. A large proportion of the food eaten is lost through the feces, and therefore metabolic deficiencies result. We get thus, the varying picture of chronic partial inanition.⁶

It has been found that the tolerance for fat in these cases is regained before the tolerance for starches. Even after several months of satisfactory diet control the taking of starch may produce a period of typical celiac diarrhea. It seems, therefore, advisable to start with a low fat, low cellulose and low buffer content, such as is found in skimmed protein milk or skimmed lactic acid milk. With this sort of diet to start with, less fat and calcium is lost in the stool. To this, cottage cheese, egg, scraped beef, sieved liver, gelatin, mashed vegetables and fruit, can be added later.

Of late much has been written of the use of bananas in this disease. Haas⁷ introduced it when he found that a child with anorexia nervosa who refused all food accepted a banana and from

then on began to improve. He postulated that some valuable enzyme must be present in the banana. More recent work by Nelson⁸ shows that whatever benefit there may be from banana is probably due to the softness of its cellulose. In the cases cited in this paper, the principles discussed above were followed out with excellent results.⁹

Before concluding, a word might be said about prophylaxis of this condition. It seems to me that there has been altogether too great a tendency to overdo the starches in the diet of the infant toward the end of the first year and during the second year. Quite commonly a baby is given cereal twice daily, a quart of milk and some bread and crackers and perhaps only sparingly of fruit and vegetables. On the basis of my experience in the cases cited and in other milder conditions of digestive disturbances in the second year of life, it has seemed far better to replace a considerable amount of the starchy foods with mashed vegetables and fruits and to give a larger proportion of protein foods. It should be added, however, that the recent introduction of cereal with added mineral and vitamin elements¹⁰ ought to aid in the prophylaxis of celiac disease.

Summary

The clinical symptomatology of celiac disease is described, in view of the rarity of this condition and the relative unfamiliarity with it on the part of many physicians. Six cardinal symptoms are emphasized. Five illustrative cases are presented together with brief accounts of the dietetic treatment. Then, the rationale or the dietary management is taken up, in the light of the available knowledge on the pathogenesis of celiac disease. Lastly, its possible prophylaxis is considered and is related to principles of nutrition and to present American diets for infants.

DERMATOLOGY AND ITS RELATION TO GENERAL MEDICINE

By MARION B. SULZBERGER, M.D., NEW YORK, N. Y.

Read in part before the Oswego and Madison County Medical Societies on April 14, 1932, as one of a series of lectures arranged by the Medical Society of the State of New York, Committee on Public Health and Medical Education. Thomas F. Farmer, M.D., Chairman. Lectures delivered by the Post Graduate Medical School of Columbia University.

IT is an obvious fact that no organ of the body can have an independent life of its own. The more we learn, the more closely knit the interrelationship of organ to organ and of the part to the whole appears to be.

It is certain that the relationship of the skin to other organs is no exception to this rule. Lengthy treatises and innumerable articles have been devoted to this subject and none has succeeded in presenting more than a segment of the entire

field. Were I to try to point out more than a small part of what is known, I should require much more time than is at my disposal this evening.

I shall, therefore, be forced to confine myself to a few specific points. I have chosen these points because of several factors: first, because of their practical importance to the general physician; second, because the knowledge on some is of recent acquisition; and third, on account of

my personal experience and observations in several of the conditions I shall describe.

Furthermore, I shall deal only with skin symptoms and manifestations which are caused by general or systemic functional disorders or by changes in one or more other organs, and not with those which are merely accompanying lesions of the same type as the internal and general affections, and probably due to the same etiological agents.

I therefore omit the infectious exanthems, the true leucemias and Hodgkin's disease of the skin and many other conditions of this order.

Nor shall I speak of skin or mucous membrane lesions which appear in certain localities, but which we have learned to interpret as signs that other skin or mucous membrane areas are also affected. I believe this group would form interesting material and that their clear-cut exposition would be of aid in calling attention to facts of practical value which are not now sufficiently universal property. In such a résumé one could speak of much which I must here omit, for instance of the necessity of examination of the axillae, groins and especially the feet for tinea in all bullous, scaly and vesicular eruptions of the hands; of how certain types of stippling of the nails or a small scaly patch on the scalp must make the physician think of psoriasis and impel him to take exact family and personal history, and to examination of the areas of predilection and of many similar guides in dermatologic and general examination.

Many skin disorders seem at first glance and, if regarded from the purely morphological and descriptive viewpoint, to be merely local changes in the outermost layers of the body's envelope. They seem superficial, both in actual depth of the pathological process and in fundamental significance.

The older dermatology was content to contemplate skin lesions in this manner. It is my object to show as clearly as possible within the limits of a short paper that the newer dermatology has learned to be aware of the deeper meaning of many seemingly only dermatologic manifestations.

We have gained a broader viewpoint and one which necessitates a more intimate collaboration between dermatology and general medicine. Dermatology has been benefited by the newer concept; so also has general medicine. The accessibility and the visibility of the skin, the facility with which repeated histological and bacteriological examinations may be made, have enriched our knowledge of many processes of general biological and pathological importance. Because the skin offers external, clearly apparent signs of the earliest beginning of many diseases, it has been of incalculable aid in the study of the early and previously ignored stages of various general

processes. For example, we owe almost our entire knowledge of the beginnings of cancer to investigations of the precanceroses of the skin.

Furthermore, skin diseases are frequently the earliest and most apparent danger signals of internal conditions. They are visible, often ugly and uncomfortable, as a rule disturbing, not to say terrifying to the patient. Many who will disregard a slight internal malaise or nondescript, vague general complaint will come to the doctor at the first appearance of a definite skin manifestation. I shall endeavor to show that the knowledge of the art of reading and interpreting these signs will often enable the physician to suspect underlying diseases of the utmost importance, and will sometimes lead to early diagnosis of otherwise unsuspected and often dangerous conditions. This will often permit the urgently required early therapy and may spare many a patient a serious illness, long suffering; and may even save a life.

The skin manifestation which looms in the foreground from the point of view of actual practice is itching. Dermatologists probably owe much of their bread and butter to this symptom, and I believe that both dermatologists and other physicians are likely to render it less consideration and study than is due. The first type of itching which I shall discuss is more or less generalized pruritus, without visible cause; that is, without manifest skin lesions. This itching is frequently caused by some internal disturbing factor, although I have seen a few cases in which an external agent was at fault and many cases in which no internal or external cause could be discovered. These last cases pass under the name of "essential pruritus." The better our investigations, the fewer such diagnoses will there be. The internal causes of pruritus are innumerable and it often requires a lengthy general and laboratory examination to find them. It is necessary, however, to attempt this in all persistent cases. The most important general causes are diabetes and uremic conditions, icteric and other biliary disturbances, internal cancers, leucemias and blood dyscrasias, and endocrine dysfunctions. A practiced dermatologist is frequently in a position to blaze the trail to the diagnosis of these general maladies, and at least those I have mentioned should automatically spring to the mind of all physicians when confronted by a persistent general itch without apparent cause.

What I have said holds in nondescript eczematous eruptions for which no cause can be discovered and which persist or recur in spite of adequate therapy. These are sometimes caused in the same manner or are the direct result of scratching. The importance of this thorough etiologic search is self-evident and although investigations may prove fruitless in many cases, the occasional discovery of a still operable carci-

noma of the prostate or colon, of an incipient diabetes or kidney disease, of beginning gall-bladder or liver trouble is sufficient reward for all the pains taken. Itching is often premonitory and the first sign of sickness in such patients. Many lives have been saved by the physician's recognition of this fact.

As illustrations of cases in which we have recently been fortunate enough to discover the underlying causes of pruritus, I shall cite three examples: a woman of 45, with severe pruritus of the right side of the abdomen and right breast, was found to have a tumor of the gall bladder, a man aged 40 had generalized pruritus discovered to be due to thyrotoxicosis. The third case does not belong strictly to the groups mentioned, as it was due to a medicament. A pregnant woman of 26 received a jar of butesin picrate ointment to relieve a slight itching of the vulva. Its use was followed by maddening general pruritus which lasted over four weeks after discontinuing the use of the offending salve. Patch tests proved that this patient's skin was hypersensitive to butesin picrate and caused a reaction of many weeks' duration.

In addition to generalized pruritus, certain forms of localized itching must be mentioned. Although one might be tempted to consider this symptom to be a local manifestation, pure and simple, this is by no means the case. Itching around the mouth, nose and anus is a well-known symptom of helminthiasis, and itching of the vulva must make one consider, in addition to local causes, the possibility of diabetes or sexual disturbances (sexual neuroses or unsatisfactory sexual relationships).

It would be possible to continue at length concerning this symptom and to mention such conditions as vaso motor instability, other neurological conditions, neurasthenias, circulatory disturbances, hay fevers, asthmas and food or drug idiosyncrasies and discuss their relationship to pruritus, but I shall have to limit myself to their bare enumeration.

The endocrine glands and their influence upon other organs have been the subject of intensive research in recent years, and in the last decade our knowledge of skin eruptions of endocrine origin has been materially increased. Unfortunately, while our knowledge of the relationship of endocrine dysfunction to certain dermatoses has been enlarged, our therapy has not been aided as much as one might have hoped. However, with the discovery of new hormones (sex hormone of Asheim-Zondek and the cortical hormone, for instance) and the improvement in the preparation of the older hormonal substances, there is every prospect of great progress in this field.

Although it is perhaps not, at first glance, an endocrine disease, I believe that we can today

state that acne vulgaris, the ordinary common or garden juvenile acne, is intimately connected with the endocrine sexual glands.

The same holds equally true in the case of alopecia of the ordinary seborrheic type. Thus, as well as acne, appears practically always during the years of sexual maturity and here the relationship to sex seems even more intimate, for in the vast majority of cases the patients are males and furthermore no eunuch becomes bald, provided he has been castrated before the age of puberty, as Sabouraud was able to ascertain in statistics gathered throughout the Mohammedan countries.

Recent investigations have shown that acne regularly appears at puberty, and that it must be considered almost physiological around the age of 12-20. Nearly one hundred per cent of youths of 18 have acne in some degree and the consideration of the condition as a morbid entity is only a question of its severity. In the light of the profound changes which are concomitant with or dependent upon the development of the sexual glands, we need not be astonished at these findings, and especially as the follicular apparatus, the seat of the disease in both acne and alopecia, is strikingly affected by sexual development. The hair of the scalp undergoes a change from childhood to adult life, the beard, the pubic and axillary hairs appear, the terminal hairs and the other secondary sexual hairs develop, and under the direct or indirect impulses of the hormones, these changed follicular activities give rise to new susceptibilities which manifest themselves in acne and alopecia. The susceptibilities may be such that the follicular and perifollicular tissues lose their normal resistance to one or more of the multitudinous varieties of germs which usually pullulate in a more or less saprophytic fashion on the skin and hair or in the follicular orifices. The possibility of the direct hormonal action on the follicle becomes probable when we consider the anatomy of the follicles and their rich vascular supply. This probability becomes even greater when we observe the strong affinity of the follicle for all manner of circulating substances, the many hematogenous and follicular dermatoses such as trichophytids and tuberculids, the follicular hematogenous drug eruptions such as certain arsenical dermatoses, and above all the often exquisitely follicular bromide and iodide eruptions.

I believe that prophecy is even more risky in medicine than elsewhere. Were this not the case I should hazard the opinion that we are not far from the discovery of a rational therapy of acne and that an endocrinologic means will come to our aid. This will be a great step in advance, in spite of the fact that in a vast majority of acne cases our present local and general methods (x-ray, etc.) lead to good results.

It is well known that our therapy of alopecia seborrheica leaves much to be desired. Our experience with the anterior pituitary hormone is still too limited and not yet ripe for discussion. It is difficult to leave these fascinating and important problems and to pass over the many other possibilities which present themselves here. For instance, the connection between acne and menstruation; between acne and gastrointestinal disturbances; between acne and focal infections; between acne and food allergy; and particularly between acne and tuberculosis. Before leaving the purely endocrinologic aspect of acne, I must mention one thing; all of the new hormonal preparations should now be given a trial in acne refractory to other treatment and in alopecias, so that we may become oriented as to their possible effects. Notably the sex and the pituitary hormones would seem to have logical possibilities.

In leaving acne and seborrheic alopecia, we must turn to rarer and therefore, in practice less important, dermatoses connected with endocrine disturbances. In some of these the connection between the endocrine disease and the skin eruption is much clearer than that in conditions already discussed. You are all aware of this in Addison's disease, and of the connection between tuberculosis of, and tumors of the adrenal glands and the pigmentary changes of the skin and other organs. You all also know of the probable chemical relationship between adrenalin, dioxyphenylalanin and melanin. All of us have recently been thrilled by the discovery of the cortical hormone and its apparently almost miraculous therapeutic power in Addison's disease.

In addition to Addison's disease, pigmentary disturbances of other kinds are directly attributable to influences of the endocrine glands. The most frequently encountered is doubtless the chloasma of pregnancy, as well as the frequent practically physiological hyperpigmentation of the mamillae, linea alba and mucous membranes. But chloasma is not a condition found only in pregnancy, for males are occasionally affected. It also not infrequently appears in non-pregnant women after at approximately the time of menopause, and here again its endocrine basis is probable.

In many other skin conditions the rôle of endocrinologic changes has been either surmised or more or less definitely proven. It is impossible to leave the group of endocrine diseases without at least mentioning such conditions as myxedema and xerosis of the skin and their definite underlying thyroid disturbance, or scleroderma and the possibly causative thyroid and parathyroid malfunction. In this latter condition I wish to mention a case which I recently had the opportunity to study in detail. Scleroderma-like changes of the skin were accompanied by distinct evidences of a disturbed calcium metabolism, with calcification of muscles and soft tissues and rarefaction

of the bones. The twelve year old girl thus affected had a greatly enlarged thyroid and a variable basal metabolic rate which fluctuated between -4 and -25 . Her general condition and skin lesions improved rapidly under iodine therapy. In consultation with many experts, it was decided that the disturbances of calcification were probably due to hyperparathyroidism. I mention this case because it is quite typical of what can be found in many cases of scleroderma.

Lack of time forces me to do no more than mention such interesting and possibly hormonal skin changes as acrodermatitis chronica atrophicans, idiopathic macular atrophies, cutis laxa, poikilodermas, dysmenorrheic dermatoses and the common striae distensae.

It has often been difficult for me to decide under what heading certain diseases should be discussed in this recapitulation. Under the heading of skin lesions due to neurological changes I have decided to mention trophic ulcers, and burns, injuries and so forth, due to the paresthesias and anesthetics. These are frequently caused by nerve changes due to infections such as leprosy and syphilis or to syringomyelia, tumors and other disturbances of the sensory or trophic nerves. In some of these anesthetics I have seen patients burn themselves deeply and extensively on the back by accidentally leaning against a stove or a hot pipe. Although such burns often covered large areas and penetrated to the bone, the patients did not notice the injurious contact until the smell of burning clothes or charred flesh made them aware of it.

In certain patients seen by the dermatologist, the manifestations are not as clearly connected with the nervous system as in the preceding examples. In alopecia areata and in canities, which both frequently follow excitement and sudden shock, the theories of focal infection and toxic or neurogenic trophic disturbance vie for supremacy, without either being absolutely established. (Sudden shocks sometimes even cause a falling-out of the nails.)

There are also many skin lesions which are due to central nervous system disease. The most notable and frequent among these are the artefacts, self-inflicted injuries, often of incredible nature, which are found in hysterics, neuroses and psychoses (and also in malingerers).

Another disease which is not to be absolutely identified with the above, but is related to them through the common basis of psychic and nervous origin, is the peculiarly typical condition known as neurotic excoriations. The patients who present this picture are the "pickers," and often unconsciously or subconsciously themselves produce lesions resembling acnes, prurigos and other dermatoses. Many forms of "tic" are the diseases known as trichotillomania and trichokryptomania belong in this group.

From these diseases it is but a step to a curious condition not infrequently seen by dermatologists. In this, the patients believe that their skin is infested with parasites, which they try to dig out. They are continually bringing to the physician's notice small bits of wool, lint, scales, hair and detritus which they believe to be alive and the infecting agent. This is certainly a neurotic or psychogenic condition, and should be referred to the psychiatrist. There are many other ways in which neurogenic and psychic causes affect the skin and we are but beginning to suspect their multiplicity and extent.

I have had the opportunity to study more closely three types of manifestations which may serve as specific instances of such influences. First, the itching and exacerbation of eruption in generalized neurodermatitis. These disagreeable and often therapeutically intractable skin eruptions are in my opinion as surely sensitization phenomena as are hay-fever or asthma and the attacks are usually due to substances to which the patient's skin is hypersensitive. I have repeatedly seen such attacks follow the ingestion of certain foods, for instance, and in almost all typical cases I have been able to demonstrate skin sensitiveness to these foods by intradermal tests. In this disease the skin reactions and systemic reactions are frequently very pronounced, often even stronger than in asthma or even in hay-fever. Furthermore I have been able to demonstrate sensitizing specific antibodies in the sera of these patients. Nevertheless I have also seen attacks precipitated in these patients without discoverable contact with the offending substances and exacerbations of itching following and seemingly caused by emotional upsets. (This phenomenon is of course also observed and is well known in asthmatic attacks.) The patients with neurodermatitis often show signs both of emotional and of visco motor instability. It is difficult to say whether the skin manifestations and neurogenic and emotional factors are simply coupled phenomena, due to the same underlying cause, or whether they are related to each other as cause and effect. If the latter is true, we cannot say which is cause and which effect. Moreover nothing is known of the basic origin of these constitutional anomalies, nor of the mechanism of the formation of antibodies and of sensitization. It might be conceivable that under the influence of the pathological nerve impulses, cells become sensitized and form antibodies to certain not otherwise harmful substances. However I know of no established proof for this concept.

I wish only to mention the two other examples promised. Common and juvenile warts, which are inoculable infections as well as acanthotic tumors, can be cured (in a definite percentage of cases) by means of purely psychic suggestion therapy.

Furthermore, I have often seen dermatophytids of the hands and body break out after emotional stress. The older school, which called these hand eruptions cheirpompopholyx, dysidrosis, exfoliatio areata manuum and eczema of the hands, was accustomed to regard this condition as a nervous phenomenon and to treat it accordingly. I believe that the newer conception that these are eczematous eruptions usually due to hematogenous dissemination of the fungi and their products from infected foci on the feet and the older neurogenic concept must be reconciled. Perhaps the explanation is as follows: the nervous upset, accompanied by hyperidrosis of the feet, maceration and lowered resistance to the fungi, brings about penetration of fungi and toxins into the blood stream and their dissemination. The same factors perhaps favor the frequent localization on the hands with their larger quantities of dead horny tissue, and tendency to hyperidrosis. I have particularly noted hyperidrosis and slight tremor of the hands as, I believe, a more than fortuitous accompaniment of severe and long lasting dermatophytids. This explanation would also account for the breaking out of dermatophytids and dermatophytosis in sportsmen and the epidemics in locker rooms, gymnasium, swimming pools, etc. The theory that the infection is picked up in these places and that the disease is spread in this manner seems to me to lack logic, when we realize that in our country almost 100 per cent of adults are constantly infected and carry foci of infection about with them continually. It seems more probable that these foci remain hidden (a soft corn, a slight fissure, a scarcely noticeable scaling, a small friable discolored area of a toe nail) and are quiescent until the addition of maceration and lowered resistance causes a flareup and spread.

While I realize that I have touched but a few salient points in the skin manifestations due to psychogenic and neurogenic factors, I must refer to the special treatises for more detailed consideration of these points.

I now wish to call attention to certain diseases which represent another group, namely, that of the nevus anomalies. As representatives of this type, von Recklinghausen's disease and adenoma sebaceum deserve attention. Both are often familial in occurrence and both are often associated with psychic changes the latter more frequently than the former. In von Recklinghausen's disease one also frequently finds malformations of the spine, and in adenoma sebaceum the association with tuberous sclerosis is not uncommon.

The familial factor observed in the nevus diseases is also to be found in conditions in all probability not related to the nevus. These are, for instance, the photo-dermatoses, such as hydroa vacciniforme and xeroderma pigmentosum. These

are both processes of the skin in which the lesions are apparently caused or their appearance precipitated by exposure to light; and as evidence of their relation to general disturbance, we have the extremely interesting finding of light-sensitizing substances (hematoporphyrin) in increased amounts in the body fluids. These conditions are sometimes fatal. They often appear in families in which intermarriage has taken place.

A much more frequently encountered type of skin disease is that which comprises those in which pathological metabolism is a factor. In this group diabetes is perhaps the most important. I believe that this disease should be discussed here, although it might have been placed with perhaps equal right in one or another of the preceding categories. In all cases of persistent pyodermas and particularly in furunculosis, in cases of monilia and thrush infections of the skin, in intertriginous, pruriginous and infected eczemas, and in skin gangrene, diabetes must be suspected and it is the duty of the physician to make the proper tests, including those for sugar tolerance. Such tests may reveal otherwise undreamed-of diabetic states in time for early and effective treatment.

Because of their relative frequency and importance, as well as on account of the new light which recent study has brought to play upon them, the xanthomas must be mentioned. It has long been considered as an obvious fact that these fatty tumors were caused by a disturbance in lipid metabolism, notably by a cholesterinemia, and that they represented nothing more than deposits (intra- and extracellular) of cholesterol in the subepidermal tissues. This theory seemed to have received its death blow when newer chemical methods and more careful investigation of numerous cases brought the following facts to light: (1) there are many cases of xanthoma and xanthelasma without increase of blood cholesterol. This substance may be either normal or even decreased in such cases; (2) many patients with increased cholesterol in the blood have no xanthomas; (3) the actual amount of cholesterol in the tumors is not necessarily above normal in quantity. In spite of these seeming discrepancies, the most recent research in this field seems to have proven that the formation of xanthoma is based upon a disturbance of fat metabolism. Regardless of whether blood cholesterol and tissue cholesterol be actually high or low, there is always a disproportion or relative abnormality in the ratio of cholesterol to other fats or lipoids in xanthoma cases. If one reproduces in the test tube the normal quantitative ratios of cholesterol to other fat substances, and emulsifies this in an aqueous medium, a finely dispersed and, what is more important, a stable emulsion will result. If one reproduces the abnormal ratios, such as found in the blood in xanthomas, an unstable

emulsion will result. This demonstrates that whatever the actual quantity of cholesterol in these cases may be, whether it be normal, high or low, its ratio to other fatty substances is such as to pathologically favor a falling-out of fatty substances from the blood and their deposition in the tissues. Knowledge of these facts makes the physician realize the necessity for examination of xanthoma cases for possible diabetes ("the fats are burned in the fire of the sugar") and liver and gall-bladder disease.

I am omitting a detailed discussion of diseases which may, in some measure, be due to disturbed calcium metabolism; such as, for instance, urticaria and angioneurotic edema, or those in which general digestive disturbances, acid-base imbalance or faulty protein-metabolism have often been held to blame. It seems to me that in spite of the vast amount of painstaking work which has been devoted to these problems, there is very little proof that any of these factors can be held definitely responsible in the majority of cases of urticarias, angioneurotic edemas, or of such diseases as eczema, seborrheic dermatitis, or psoriasis.

If one may be permitted to include the avitaminoses among the metabolic disturbances, it must be stated here that with the exception of the older pictures recognized in scurvy, very little is known and much will still be learned. In pellagra, which has such definite and typical skin lesions, and such marked accompanying disturbance in internal organs and psyche, the rôle of avitaminosis and of toxic substances and infection is still a subject of controversy. I take this opportunity of mentioning only one of the cardinal symptoms in scurvy, and that is the tendency to hemorrhage and purpuric lesions, both in the skin and mucous membranes.

This brings me to an extremely important group of skin diseases, not necessarily those metabolic, but those in which the extravasation of blood is the essential feature, namely the purpuras. I must dismiss with brief mention the purpuras due to blood dyscrasias, such as purpuras in leucemias and anemias and those of the thrombocytopenic type, and merely call attention to the necessity of bearing these diseases in mind and investigating in this direction when confronted by purpuric skin lesions of unknown origin. Of even greater importance than these are the purpuras associated with the infections for instance those so frequently seen in sepsis. It seems necessary, however, to again recall the fact that any generalized infection or bacteremia as well as many drug-eruptions may manifest themselves in extravasations of blood under or into the skin, varying in size from pin-point petechiae to large areas of ecchymosis and suggestion often resembling large bruises at first glance. Among the forms of purpura which may be due

either to bacteria or their toxins, I must mention rheumatic purpura, or Schoenlein's disease, and Henoch's purpura, which is associated with gastro-intestinal crises. (Almost everything I have said concerning the purpuras due to bacterial or toxic agents, or to drugs can, *mutatis mutandis*, be applied to the erythema nodosum and erythema multiforme types of eruptions. These, together with the purpuras, typify the purely symptomatic skin eruptions and are almost always indicative of underlying general disease and bacteremia and/or toxemia in the widest sense of the word. They are all symptoms which may be caused by a multitude of different circulating, noxious agents including, for instance, tubercle bacilli, trichophyton fungi, lepra bacilli and many other micro-organisms.)

As I have already indicated, I am leaving entirely out of consideration conditions in which the skin manifestations and manifestations in other organs are caused by the same etiological factor, are part of the same general pathological process as the internal disease, and have the same, or similar, histological findings. For this reason I here omit the actual leucemias of the skin, Hodgkin's disease of the skin, tuberculosis of the skin, the skin metastases of internal cancer, all of the acute infectious exanthems, and the typical skin manifestations of syphilis and leprosy, as well as many other perhaps equally important diseases.

In the points I have outlined, I hope that it has been possible for me to make clear that the skin acts as a sort of mirror of internal conditions; often not as a true mirror in which the disease is reflected in its actual form and color, but rather as one which gives a distorted picture which we can interpret only if we have been taught to read the signs.

An excellent example of the usefulness of the skin as a means for judging the condition of the general organism is offered by its rôle as an immunological testing-ground. Two factors contribute towards giving the skin its important place in this regard. First, as I have stressed elsewhere, its accessibility and visibility; and second, the fact that changes in resistance and susceptibility of many distant organs and many general conditions are frequently coupled with a synchronous change in skin reactivity. A few examples of this are found, for instance, in the Schick test, in the Dick test, in the tuberculin and trichophyton tests, whether applied according to the methods of Mendel-Mantoux, of von Pirquet, of Moro, or of Poincarré, or by the patch-test method. To these older examples, recent years have added many more important skin tests, such as the highly specific Frei test in lymphopathia venereum (lymphogranuloma inguinale) and its many manifestations, such as high rectal strictures, especially in women, and

chronic ulcerative and elephantastic processes of the vulva and anus.

The tests of Dmelcos and Ita-Reeinstierna are a valuable aid in the diagnosis of soft chancre and its differentiation from other conditions. Although, even today, I could lengthen this list considerably, I believe that the future will prove that skin tests will be of help in many other diseases in which they are now not used, such as in malaria, spinal meningitis, poliomyelitis, and in innumerable other infectious and non-infectious pathological processes.

The almost universal participation of the skin in the changed reaction of other parts points to this organ as one of particular immunological significance. Many observers have, therefore, come to consider the skin not only as an envelope for the purpose of physical protection, and not only as an organ of excretion but also as a protective organ in a wider sense, namely as perhaps the main site for the elaboration of protecting anti-bodies. My own experience and experiments point emphatically in this direction. For this reason I believe that many immunological procedures would create a more favorable antibody protective response were they administered by methods favoring an intimate contact with the superficial skin-layers (for instance, by intradermal injection, by inunction, or by scarification and the application of antigen) rather than by the now more frequently practiced subcutaneous, intramuscular or intravenous injection.

It does not seem necessary to speak at length concerning the value of skin tests in such conditions as asthma, hay-fever and vaso-motor rhinitis. American medicine has done pioneer work in this field and we are all well acquainted with the relief many sufferers have obtained through the information derived from such tests. I wish to emphasize only two points: first, that it seems possible that we may achieve more efficient desensitization in these diseases by adopting the intradermal methods which I have mentioned; and second, that all skin tests in order to be properly executed and evaluated must be carried out and observed by physicians not only possessed of logic and judgment, but also of wide experience in this highly specialized field. Innumerable errors are continually being made in this particular branch of medicine and their results reflect undeserved discredit upon the method.

In closing, I should like to add that what I have said regarding skin tests applies equally well to the judgment and experience necessary not only in the diagnosis of all the skin diseases which I have mentioned, but also in the consideration and the tracing of their possible connection with other and general pathological conditions. I hope that I have succeeded in showing that dermatology can today be of assistance to

the general physician and to specialists in other branches, and that dermatologists have gained a wider viewpoint and left behind a system of purely morphologic diagnosis and empiric local therapy. In this wider field the necessary collab-

oration of dermatologist and general practitioner, dermatologist and other specialists, and dermatologist and laboratory becomes evident, both for the study and treatment of the individual case and for the progress of medicine as a whole.

GENERAL PRACTICE BEFORE SPECIALISM OF PRACTICE*

By WM. B. D. VAN AUKEN, M.D., TROY, N. Y.

THE term General Practice here used means that type of practice which treats and cares for all medical conditions, most minor surgery work, obstetrics, and the more common affections of the eye, ear, nose and throat. I do not believe that a physician should regard himself as capable of properly treating all medical and surgical conditions and diseases which come to his attention. The recent additions to medical knowledge have made it utterly impossible for any individual to absorb more than a portion of it.¹ Apropos of this, to say that specialism in medicine is not necessary is absurd.² Further it is reasonable to say that all physicians limit their work. The family doctor may even so restrict his work as to classify himself as a specialist.³

The term Specialism of Practice here used means such limitation of a physician's practice that causes him to restrict all of his medical work to one of the well recognized specialties or allied specialties such as Ophthalmology, Public Health, Otology and Laryngology, General Surgery, Tocology and Gynecology, or Gastro Enterology, etc.

In this article an effort will be made to set forth some of the advantages and disadvantages of a general private practice preceding a specialty practice.

It is generally admitted that the man who succeeds best in a vocation is usually the man who is happy with his work—one who has found the occupation of his natural choice.

Many have failed because they did not follow the walk in life best suited to their inclinations and aptitudes.⁴ A proper selection of a specialty I believe, may only rarely be made without acquainting oneself with the various fields of general practice. We are far better able to pick a candy of our choice by first tasting each morsel.

One or more years of general hospital internship cannot give one the obligations, responsibilities, hours and types of service that a few years in private general practice can give. Without these years of general training

the specialist fails to understand the problems that vex the family physician.⁵ He lacks breadth of vision and often operative correction of supposedly serious yet trivial defects are undertaken not only unscientifically but at times innocuously.

Likewise specialists in public health, lacking the experience of a private general practitioner, at times try to promote activities doomed to failure from the start because of their obnoxious nature to the back-bone of public health—the general practicing physicians.

General practitioners have the unique experience of being the first to recognize the condition which the specialist later treats. He watches the remote as well as immediate results of the work done by, not one, but many specialists as the patients whom he refers to the specialist, returns to him for later care and observation. Such observations often develop conservatism rather than radicalism particularly as regards surgical intervention.

By indulging in general practice before a specialty, a physician can test the application of his college and hospital education. He can mould his education into knowledge by assuming and continuing with the full charge of a great variety of private patients. Such physicians may later see their specialty in its proper relation to the general whole and not to one particular part of it.⁶

The more thorough that general knowledge is, the better one can care for a local condition and obviously the reverse is true. If the specialist is not trained in general medicine he all the more should seek the help of the family physician.

I believe it is safe to state that most doctors cannot establish much of a private practice in any branch of medicine including the so-called general practice till they have continued at least three years in that branch. Each year after that will greatly add to their fund of knowledge and assist in ripening their faculties and judgment.

The ability to handle patients tactfully does not come without contact with a large prac-

* Read before the Medical Society of the County of Rensselaer, April 12, 1932.

tice. A gross error of tact or technic is much easier to recover from while in general practice than when practicing a specialty. A patient may say, "Dr. S. is no good when it comes to fractures, but he certainly is fine with babies." It is much better to fail in one thing and succeed in others, than to fail in the only one with no others with which to surpass.

When a patient seeks the advice or care of a specialist, that patient has a right to expect maturity of judgment and experience as well as technic or ability. I believe most patients are somewhat disappointed when consulting a highly reputed specialist for the first time, they note a man of the twenties or early thirties who by his very actions and words as well as appearance bespeaks youthful adventure, enthusiasm and daring courage. In exceptional cases a doctor may spend the most of his early medical career doing institutional work and at the age of 35 he may start out for the first time on his own initiative. Such men are rare and though more mature in judgment and experience they have yet the lessons to learn about the art of the practice of medicine.

In these days of speed and economic pressure, a patient who is under the care of a specialist for a local condition and who coincidentally acquires another disease or disorder not related to but associated with her primary condition and who is post haste sent to one or more other doctors, may believe that she is pan-handled too much and may rebel.

If a good foundation of general practice makes it possible for that physician to recognize the psychic or economic problems of such a patient and to successfully treat or care for the associate disorder, he makes himself very valuable to her in a manner that the specialist without general practice cannot.

When a doctor who has practiced general medicine five or more years, decides to qualify for a specialty and obtains an appointment in a specialty hospital the work he sees and does I believe, is a greater source of information and help to him than it would be if he had not been confronted with similar problems in his former general practice. I do not believe that a general hospital born specialist will absorb as much from his specialty training as will a general practitioner born specialist. The first never has been compelled to solve any intricate diagnosis or procedures by himself while the second may have already met such problems perhaps in a more crude way, and hence appreciates the artful technic of an expert.

The average type of a county medical meeting as well as general hospital staff meetings

appeal but little to a hospital born specialist unless he has had more than the usual general hospital experience. By having a wide experience in general practice before specializing, a physician will enjoy such meetings. He will know of the problems of his associates and will not be hypercritical or megaloccephalic. Not having been raised in the forest he will be able to see the lakes, the gardens and the vast open countryside.

While it may seem that the ideal has already been put before us we must not forget that there are disadvantages.

The first one is financial. It is somewhat against human nature to give up a bird in the hand for one in the bush. When a physician has been engaged in general medical practice for more than five years, if he is any good at all he will have a valuable practice from a financial point of view. If he has not such a practice I believe he might as well withdraw and run a subway train or find some other vocation that is better fitted to his nature. To qualify for his specialty he is obliged to let all that valuable patronage that has cost him so much, go to the other fellow and to begin at a later date at the bottom of the ladder, oftentimes heavily in debt. Furthermore we must not forget that when starting the practice of a specialty it will probably take three or more years before the practice will keep one reasonably busy or satisfactorily compensated. It is a sacrifice that not many care to make.

The second disadvantage is the marked tendency which most specialty hospitals show toward excluding resident appointments to general practitioners on the basis of their minds being more or less closed to new ideas. This is particularly true of the Tocological and Gynecological hospitals. I have personally experienced such difficulties and have met with others who have also been confronted with like obstacles to the attainment of a hospital appointment in Tocology and Gynecology. They prefer to appoint a man to their resident staff who is fresh from another hospital; one whose brain is plastic. It has been written⁷ that it seems wiser now for a young man to enter a specialty after a good hospital training than later in life; as it is not only easier to assimilate ideas, but the development of technical skill is easier and it is probably almost impossible to develop it later in life. This may be true but it does not seem to accord with the opinions of Nicoll,⁸ an editorial,⁹ Phippen,⁶ and Morgan,¹⁰ all of whom are strongly in favor of a preliminary five years or more general practice experience before specializing.

I believe that with Specialism as well as

with all other lines of activity there is no short road to success. Those who truly will succeed must give considerable time and ef-

fort to their task and pay the price, no matter what the cost to themselves in time, effort and money.

MECKEL'S DIVERTICULITIS IN AN INFANT

By RALPH R. MOOLTEN, M.D., NEW YORK, N. Y.

The case reported was from the surgical service of Dr. Charles Gordon Heyd, New York Post-Graduate Hospital, Dr. John F. Erdmann, Director.

THE occurrence of an acute surgical abdomen in infancy and childhood is not common. Next to the appendix, a Meckel's diverticulum is the most frequent cause. When this later condition does produce disease, the symptoms are often so varied and obscure that diagnosis is difficult. I feel justified, therefore, in reporting a case that may contribute a little to a scanty literature.

Quoting from Dr. W. Ray Shannon, in the *Archives of Pediatrics* for December, 1928: "Meckel's diverticulum is a remains of the intestinal end of the omphalomesenteric duct. According to Johnson, it exists in about two per cent of all persons. According to Fitz, in the new-born it lies about 12 inches above the ileocecal valve, while in the adult this is increased to about three feet. The diverticulum may be long or short, may or may not have a separate mesentery or may be contained within the mesentery of the small bowel. It may be fixed at its distal extreme to the umbilicus or to any structure within the abdominal cavity. It is often conical in shape with the base large, even approaching in size the diameter of the small bowel at this point. According to Christopher, it usually has the same coats as the intestine, the mucous coat containing Lieberkuhn's glands and Peyer's patches. This same writer quotes Aschoff as saying that it may contain gastric glands, ciliated epithelium and even pancreas anlage. A certain number of Meckel's diverticuli are associated with deformities at the umbilicus, and marked deformity or abnormality of the navel should therefore always bring to mind this possibility."

Meckel's diverticulum can produce disease in several ways:

1. *Mechanical*—By virtue of the fixation of the tip of the diverticulum to the umbilicus or another viscus strangulation or torsion of the adjacent small intestine can occur and produce intestinal obstruction.

Intussusception can result from the invagination of a diverticulum.

2. *Ulcerative Condition*—Ulcerations of a diverticulum have produced hemorrhage and even perforation.

3. *Inflammatory Conditions*—

(a) *Acute*—Here the situation resembles acute appendicitis and the sequelae are also similar.

(b) *Chronic*—This usually occurs at the base of a diverticulum and the resulting fibrosis may produce partial or complete occlusion of the bowel.

The case I have to report is one of acute diverticulitis with perforation. A peridiverticular abscess was formed. It was well walled off, so that a general peritonitis did not follow:

CASE REPORT

Louis Preziosi: Chart No. 72765. Age: 7 months (born July 20, 1931). Birth Weight: 6 pounds, 5 ounces. Normal delivery at term.

Past History: At four months of age, the child was first treated in the out-patient clinic as a feeding case. At that time physical examination was essentially negative. After a protracted treatment, the complaint of vomiting was checked and the child made normal progress.

Present Illness: Twenty-four hours preceding admission, patient began to cry persistently and seemed very irritable. The abdomen was tense and somewhat tender, and the temperature rose to 103.2.

Examination: On admission, revealed a plump, well-developed child who did not look ill. The child did not cry until disturbed and took its food well. Complete examination revealed the following positive findings:

(a) Ear drums, congested, absent light reflexes, but no definite bulging.

(b) Breath sounds over right upper lobe, louder and slightly harsher than on the left side. Examiner made a note of questionable significance.

(c) The abdomen was markedly distended, very tense, and palpation caused crying. There were no palpable masses or viscera. Rectal examination was negative and was followed by the expulsion of considerable flatus and a fairly large normal stool.

Diagnosis at this time was:

1. Early pneumonia.
2. Bilateral otitis media, chronic.
3. Possible acute abdomen.

During the next several days, various examinations and consultations were made and the conclusion was to rule out all findings, except those of the abdomen. During this time the child did not vomit, took his food well, and passed normal and sufficient stools. The only significant factors were an elevated temperature and a distended abdomen.

On February 14, 1932, I was called to see the case in consultation. Although I was extremely dubious about the presence of a surgical abdomen, at the insistence of Dr. De Sanctis, whose opinion was of an acute appendicitis with abscess, I performed a laparotomy.

Operation: The abdomen was entered through a right rectus incision. About twelve inches proximal to the ilio-cecal valve there was a

Meckel's diverticulum with abscess which was definitely localized and adherent to the lateral abdominal wall on the right side. The abscess cavity was drained. No perforation was discernible in the diverticulum. It was believed that a pin point perforation had previously occurred, thus causing the formation of an abscess which fortunately became walled off and that perforation subsequently sealed itself. The base of the diverticulum was as broad as the lumen of the intestine. To remove it would have involved intestinal resection, which was not deemed advisable because of the patient's general condition. However, a prophylactic appendectomy was performed.

Post-Operative Course: During the four days following the operation the child seemed to be doing very nicely. His temperature was returning to normal and the surgical wound was in good condition and remained so during the remainder of his time in the hospital.

On the fifth day following the operation after the child seemed to be doing so well, he began to develop complications directly associated with involvement of both middle ears. Bilateral myringotomy was performed, but was not followed by favorable response. A gastro-intestinal upset intervened and, finally, a broncho-pneumonia.

In spite of four blood transfusions, at no time during this period did the child's general condition seem to indicate that he would survive the numerous intercurrent infections, and he died on March 12, 1932.

Autopsy Findings:

1. The abdomen showed adherence of small intestine to anterior abdominal wall. No obstruction, no purulent material, no injection of peritoneum.

2. Chest showed small amount of mucopurulent fluid throughout the bronchi. Both lungs collapsed.

3. **Head:** Both mastoids contained thick purulent material.

A REVIEW OF THE PROBLEM OF ACUTE FOOD INTOXICATION*

By G. HENRY KNOLL, M.D., LE ROY, N. Y.

FOOD poisoning is a topic in which my interest was first aroused by a major tragedy occurring in the city of my birth during the course of my Junior year at college. I was, at the time, just in the throes of my introduction to bacteriology and the occurrence left an indelible impression on my mind.

To add interest to the consideration of the topic, a brief recounting of this terrific catastrophe may be justifiable. C. C. W. was a man of prominence and wealth in our community and in addition one whose friends were legion. He had always had military connections and in the summer of 1917 went overseas as a Colonel in (if my memory serves me rightly) the Rainbow Division. In the late

* Read before the staff of St. Jerome Hospital, Batavia, N. Y., March 14, 1932.

summer of 1919 he returned from overseas with the remnants of his command and on August 23, a banquet was held in his honor at one of the nearby country clubs. Seated at the hostess table were eighteen people. Within twenty-four hours after the serving of the dinner, fourteen people were acutely ill and in a period of a week eight of them had died—among them being Colonel W. and the hostess who gave the dinner in his honor. Dr. Charles Armstrong, assistant surgeon of the United States Public Health Service, was immediately sent to investigate the outbreak and careful epidemiological and serological investigation proved that the victims died from botulism—the toxin of the bacillus botulinus being present in ripe olives bought especially by the hostess for the occasion. So much then for the grim tragedy and drama of a certain type of food poisoning when it like lightning does strike in the most unexpected spot. There are, of course, almost innumerable forms of human intoxication by food. Many of them it is not our purpose to include in this paper. Such considerations as rather rare foods themselves chemically poisonous such as certain strains of mushrooms; metallic poisons finding entrance to foods either through homicidal effort or from the composition of containers; and certain specific diseases transmitted by food, such as typhoid fever, tuberculosis and septic sore throat we shall omit. Were one to try to encompass all types of disease and intoxication finding entry to the body through the digestive tract, the field would obviously be much too broad for a single paper. I shall confine this paper to certain little known poisonous effects of some of the common food substances and to that large group of acute illnesses caused by bacterial agents of which a physician usually thinks under the head of food poisoning.

There are certain commonly used foods which are in themselves in certain species or at certain times inherently poisonous. Most common among these are the sea foods. Although poisonous fish are rare in our waters, in tropical waters of certain locations they abound and to eat them is fatal. These practically all belong to the group of puffers or the balloon variety. Clams and mussels at certain times of the year are very poisonous—a type of poisoning not yet well understood. The toxin which they contain has been isolated but its cause has not been determined. It is known to be entirely independent of the spawning season of the mollusc, to have no relation to the flora and fauna on which they live and to be independent of conditions of pollution of the water in which they grow. It resembles in its action cyanide poisoning

and the Public Health Service combats it by testing specimens from the mussel beds continuously. Whenever toxic forms are found the beds are quarantined and kept so until the crustaceans are once more free from toxicity. One seldom thinks of potatoes as being poisonous and yet they are markedly so under certain conditions and outbreaks of potato poisoning are not uncommon. The potato is a solanaceous plant belonging to the same family as deadly nightshade, the source of belladonna. It contains in small amounts a poisonous alkaloid called solanin. This is normally present in such slight amounts as to be negligible but in potatoes that grow partly out of the ground or in ones that have begun to sprout it is greatly increased and may cause toxic symptoms. The alkaloid is unaffected by cooking. Poisoning occurs more frequently on shipboard or in locations where potatoes are not carefully pared. Care to pare deeply and remove all the eyes reduces the likelihood of poisoning. Death is rare yet the condition may cause extreme prostration. Rhubarb contains oxalic acid—one of the favorite homicidal drugs—and the leaves contain it in sufficient amounts to cause fatal poisoning. Cherry stones, peach kernels and bitter almonds, although not classed as foods, contain prussic acid in fairly large quantities and children have died from eating them.

So much for various common foods containing chemical poisons. But the ordinary acute gastro intestinal upset with definite evidence of intoxication following the ingestion of food is a very different affair and is of bacterial origin. Before we can go on and classify these conditions both chemically and etiologically, it is necessary to clear the decks of some very misleading nomenclature in order to avoid being led entirely astray. In 1850 an investigator named Selmi coined the word ptomaine and thus gave rise to a misconception regarding food poisoning which is not yet entirely wiped out. The conception at that time was that putrefying flesh gave rise to chemical substances which were poisonous. The word ptomaine means corpse and gives graphic illustration of the clinical results of food poisoning in those days. Later it was proven that decaying meat does give rise to various poisonous alkaloids and the ones isolated were called cadaverine, putrescine, etc.; names indicating graphically the state of decomposition of the food product from which they were isolated. But from proving the presence of such products to assuming their responsibility for food poisoning is quite a chasm and not so easily bridged. In the first place they do not start to form until putrefaction has been in progress for a week and

secondly they are then only very slightly toxic. Food then to contain ptomaines of any toxicity must be in a very advanced stage of disintegration. To quote Savage: "No one would be stupid enough to vend such food, no one would be rash enough to eat it." Ptomaine poisoning is a myth and the term a misnomer. It has done much to circumvent true progress for it has served as a cloak for professional ignorance and an excuse from active investigation of many outbreaks of food poisoning which have occurred.

These cases which we have in the past diagnosed as ptomaine poisoning were instead due to poisoning by the products of bacterial growth in contaminated food and the organisms responsible are in the order of their importance as follows:

- 1 Bacteria of the Salmonella or hog cholera group
- 2 Bacillus botulinus
- 3 Staphylococcus
- 4 Bacillus proteus

Up until recently the first group was considered to be responsible for all cases aside from true botulism but Robinson & Taylor have recently reported the development of a definite toxic substance in pork infected with Bacillus proteus (the hay bacillus) and Ilsey has reported an outbreak at Colgate University due to Bacillus proteus. L. O. Jordan on December 5, of last year reported six cases definitely proved to be due to Staphylococcus aureus and albus and believes that many of our cases in this country are of that origin. In some of these cases the symptoms were very violent and the prostration severe although no deaths were reported. They differ clinically from cases of the Salmonella group in that they develop within two to four hours after the ingestion of food instead of from six to twelve and in that the mortality is zero as compared with one to two percent.

The Salmonella, hog cholera or paratyphoid group of organisms, are the ones responsible for more outbreaks of food poisoning than any others. They are of the same family as the typhoid bacillus and occupy a position midway between it and the colon bacillus. The more important are Gartner's Bacillus (Bacillus enteritidis) the hog cholera bacillus (Bacillus supestrifer) and Bacillus terrestris. They live in the intestinal canals of animals as well as in the soil so that food infection may be due to fecal contamination, soil contamination or to the food itself being the flesh of an infected animal. Outbreaks have recently been proven to be due to duck eggs the duck being very lax in her selection of a place to lay, and the egg lying in moist manure

until well infected with Bacillus enteritidis. The symptoms are due not to ingestion of the organism into the body but to ingestion of a toxin which it produces while growing in the food. This toxin is not killed by heat and therefore once formed cannot be gotten rid of. The more food is handled and the longer it stands around after cooking the more chance is there for it to be contaminated and for the germs to grow. Meat and milk products are the most frequent offenders.

The symptoms are nausea, vomiting, abdominal pain and diarrhea coming on suddenly six to twelve hours after the ingestion of the food responsible. The degree of prostration is usually proportional to the severity of the diarrhea. In fulminating cases death may ensue within twenty-four hours, but as a rule the infection is not severe and recovery takes place in a day or two. The severe type may resemble cholera and was formerly called cholera morbus. Treatment is entirely symptomatic and consists chiefly of measures to promote vomiting and purging. Pain may be controlled by hot applications to the abdomen or morphine. There is no specific treatment.

Now, what foods should we suspect and guard against to prevent acquiring this infection? The infection usually takes place in the food itself before, during or after its preparation and through faulty handling or incomplete cooking or both the food becomes toxic. Frozen foods, cold storage foods, improperly handled meat, fish and shell fish are especially susceptible. Cream soups and cream sauces also especially when made in quantities and kept warm for some time are frequent offenders. Cream fillings and gelatine desserts furnish excellent media for the growth of germs. The advice of LaWall is good: "Don't fear sound fruits—fresh or canned. In a dirty place or where you suspect the sanitation of the kitchen, stick to roast beef, potatoes, bread and butter, fruit and coffee or tea, for these foods are the least hazardous. Shun cream soups and sauces, cream filled desserts and prepared foods containing gelatine, for these are splendid culture media for invading bacteria."

We have discussed the most common causes of food poisoning. There remains for discussion the most fatal type—botulism. Botulism has been known clinically by German physicians since 1735 but the organism responsible was not discovered until 1895. In that year Van Ermengen discovered it and named it the Bacillus botulinus from the Latin botulus for sausage. This was because at that time meat products alone were supposed to cause the disease. The Bacillus botulinus

is an obligate anaerobe, that is it grows, reproduces and forms its toxin only in the absence of oxygen. There is but one exception to this rule. When implanted in a medium together with certain other organisms such as *Staphylococcus* or *Bacillus subtilis* it will sometimes grow under aerobic conditions—a fact which probably explains its being occasionally found on the surface of some articles of food. The presence of oxygen in its environment, however, cannot be relied upon to kill the organism. Under such conditions it surrounds itself with a thick impermeable spore which protects it from damage and in which it remains protected until anaerobic conditions are again established. It is this spore form which permits it to survive the heat of ordinary canning processes. *Bacillus botulinus* lives in the soil and is widely distributed throughout the western United States, France, Germany and southern Italy. It has also been found in the intestinal tracts of animals—especially hogs—so that it may gain entrance to fruits and vegetables either by soil contamination or fecal contamination. So far as meat is concerned the bacterium may and often does grow in the tissues of the animal.

Now botulism is not caused by infection of the human body with *Bacillus botulinus* but is caused by poisoning of the human body with a very powerful toxin or poison which the *Bacillus botulinus* gives off in the course of its growth. This is a true exotoxin—that is it is given off by the bacterium without the necessity of destruction of the organism itself. Since the bacillus can grow only in the absence of oxygen and since it gives off its toxin only in the growing form (not in the spore form) it follows that the only foods which may contain botulinus poison are those from which oxygen has been excluded long enough to permit growth and elaboration of toxin—namely, canned foods—meats, fruits or vegetables. This toxin is so powerful that it is not necessary for one to swallow any of it to obtain a fatal dose. Even tasting food which contains it may prove fatal. Fortunately, however, the toxin is very thermolabile so that if the food is boiled for a short time it is destroyed and is absolutely harmless. Therefore although the spores resist boiling temperature for from five to six hours and are thus sometimes unharmed by the heat of canning, their product the toxin is readily rendered innocuous by heat.

The *Bacillus botulinus* is responsible, in addition to human botulism, for a disease called limberneck in fowls and forage poisoning in animals. The latter get it usually from silage.

Now from what canned foods are we likely to contract this disease? The number is almost legion. But there is always one prerequisite—faulty canning. The commercial canners now are well aware of the danger and autoclave their foods with steam under pressure—killing the spores. For that reason practically all outbreaks in the past ten years have been due to home canned foods. The cold pack method is especially pernicious. This is even more true in high altitudes where the boiling point is low. In the past thirty years there have been one hundred ninety-two outbreaks of which seventy-two percent have been due to plant products and eighteen percent due to canned meats. The *Bacillus botulinus* is readily killed by an acid medium and for that reason non-acid vegetables such as string beans are especially susceptible. String beans head the list not only for this reason but also because spoilage in beans is slight and difficult to detect and in addition because they are often used cold for salads and the odor is masked by mayonnaise. Corn is second probably for the same reason. Olives are third but most of the olive outbreaks were prior to the one reported at the beginning of this paper. Spinach stands fourth. If no home canned foods were eaten without heating it is probable botulism would be almost entirely unknown. In contrast to *Salmonella* poisoning where the character of the food is usually not changed at all—*botulinus* infected food usually shows definite though mild evidence of spoilage. The cans may bulge or contain gas and the food is usually somewhat soft and has a queer taste and odor. If no questionable can was ever even tasted the incidence again would be reduced. We can appreciate the wisdom of this when we reflect that so far as can be determined the death rate among those who have tasted *botulinus* infected food in the past thirty years runs between sixty and sixty-five percent.

The symptoms are most unusual. There are two clinical types depending on whether or not there is gastric disturbance. The toxin is, like that of diphtheria and tetanus, a true neuro toxin and achieves its effect by uniting with nerve tissue. In the approximately one-third of the cases therefore which have their onset with nausea, diarrhea and vomiting coming on early, lasting twelve to thirty-six hours and disappearing with the onset of the nervous symptoms, the gastroenteritis is apparently the result of local irritation from the ingestion of spoiled food. In the other two-thirds the nervous symptoms are the first to appear; usually eighteen to thirty-six hours after the food has been taken. The first symp-

toms may be an obstinate constipation although the earliest ones are often great lassitude and fatigue with sometimes dizziness and headache. Visual disturbances which are almost routine appear early. These consist of scintillation and dimness of vision with early involvement of the third nerve, ptosis, mydriasis, loss of light reflex and practically always diplopia. Loss of accommodation follows and nystagmus and vertigo are common. Soon the patient develops difficulty in swallowing and talking and a sense of constriction in the throat. The general muscular weakness is very striking as the patient is often unable to raise even his head or arms from the bed. As a rule they suffer no pain and mentality usually remains clear until shortly before death. A great apprehension of death is frequently a horrible part of the picture however. Inhibition of secretions comes on fairly early and the victims complain bitterly of intolerable dryness in the throat. There is no characteristic change in the blood pressure and the temperature is usually subnormal. This coupled with the very rapid pulse of the later stages presents a striking picture. The patient usually dies a respiratory death and the heart action often continues for several hours after respirations have ceased. Cases which recover have a long slow convalescence. The strangling and dysphagia disappear first and the muscular weakness and visual disturbances clear gradually over a period of months. Recovery when it occurs is complete and leaves no disability.

Treatment rests on early diagnosis and prompt action. The only treatment of the slightest avail is the early intravenous administration of anti toxin which in this community is obtained from the State Department of Health at Albany. As is true with

diphtheria and tetanus, anti toxin, if it is to be of any avail, must be given before the poison has sought out and united with the tissues of the central nervous system. After the nervous symptoms appear no treatment is of any avail.

Now what is to be learned from this rather gloomy picture? First there is increased care in our methods of home canning. All home canned foods should be absolutely sterilized. If this is impossible non-acid foods should be acidified with citric acid to a pH of 4.5 and heated to one hundred degrees for a short period afterwards or put up in a ten percent brine. Secondly, home canned products should never be eaten unless thoroughly heated after removal from the can. Thirdly, canned foods showing the slightest evidence of spoilage should be discarded without even tasting.

What may we as physicians do to aid in the solution of this problem? First we should discard the ancient and misleading diagnosis of ptomaine poisoning and make an honest effort for an accurate bacteriological diagnosis on every case of food poisoning seen. Much is still to be learned and when suspicion centers on some article of food, prompt sending of any of the food left over together with specimens of stool and urine from the patient to a reliable laboratory may lead to an accurate diagnosis. Cases are on record where spoiled beans have been fed to chickens and the whole flock promptly died. Intelligent investigation of such an occurrence leading to discovery of the food responsible and the destruction of any infected food remaining on the shelves may save lives.

We may never see a major botulinus outbreak. It is to be hoped we never do. But should we see one, lives will depend on our prompt recognition and action.

Whenever a medical society or one of its committees discusses a new problem, questions of principles, standards, and policies arise. Physicians are bound by the *ancient landmarks* or established policies of their profession; but *modern progress* in science and sociology often compel radical changes in the older standards and the adoption of new methods.

Written principles and policies may be used for two purposes, diametrically opposed to each other:

1. A refuge from action.
2. An incentive to action.

The subject of medical publicity affords an illustration of the changed conditions of these modern days. It has always been a fundamental principle of the medical profession that a doctor shall not lend his support to any form of advertisement of himself. But during the last quarter of a century group action in medical and health affairs has developed along two lines.

1. Medical Societies have expressed the standards and policies of the medical profession in the practice of medicine and public health by individual doctors.

2. Governmental officials and lay health organizations have inspired the people with a civic consciousness regarding their duties in public health lines.

The medical society has become the *doctor*, and the municipality is the *patient* in everything pertaining to public health. It therefore follows that the medical society must instruct the people regarding public health affairs, just as a doctor in private practice must instruct his patient and family regarding the nature of the illness and the means of its cure and prevention. But when a doctor delivers a public health lecture or gives a radio talk, or writes a press release, he must "advertise" himself. Many doctors therefore are tempted to invoke the ban on self advertising as a refuge from taking part in popular medical education. But others invoke the equally ancient and binding principle that physicians shall use every possible means for curing

their patients and preventing disease, including public health education by individual doctors in the name of the medical society.

The principle is that, since the medical society is an impersonal body, it must assign one of its members to act for it in matters of publicity and education. While that doctor will necessarily receive public notice and "advertising," yet he also calls attention to all the other doctors, and their ideals and aspirations.

The principle of advertising the group, or medical society, instead of the person, or individual physician, applies equally well to the doctors' relations to governmental officials and leaders in lay health organizations. Doctors and medical societies are tempted to praise those persons who agree with them, and to condemn their opponents. Personalities, either of praise or of blame, lead to jealousies and factions which impede progress. For example, it is not usually wise for a medical society to publish an article praising an official by name, but the society can accomplish the same end by praising the work which has been accomplished and the agreements which have been evolved. The particular government official or board that did a piece of work stands in the same relation to the activity that the individual doctor stands to his medical work.

Physicians are opposed to *personal* publicity as strongly as ever, but they favor publicity regarding the activities of medical societies and of lay groups promoting public health.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Eye-strain among school children The following editorial in this Journal of September, 1907, will apply to the year 1932 also.

"Cornell calls attention to the responsibility for these conditions (eye strain), and places it upon the medical profession, the teachers, and the parents. The former has not sufficiently sounded the alarm and insisted upon correction of eye defects. The teachers do not know about them. He says there is a certain amount of humor in the contemplation of a teacher, drilling into her class the baneful effects of alcohol on the 'lining of the stomach' and its production of 'hob nail liver' while she is unconscious of the squinting of the heavy eyed, round-shouldered child before her. Parents are often culpable in their indifference. Sometimes they say 'Kindly leave this matter to me, it is none of your business', or, after repeated advice to have the child provided with proper glasses, they announce that a break-

fast of toast and oatmeal is the best remedy for the headache. From 22 to 34 per cent have the necessary remedy applied to correct the visual defect.

'The effects of defective vision upon the general health has been studied and written upon by Gould to a degree never before attempted, and it is to him as much as to any single man that this crusade is due. The relation of poor vision to poor scholarship is shown by Cornell. He grouped the children whom he examined into three classes, and always found the highest percentage of good scholarship with the lowest percentage of poor vision, and in the classes with the lowest percentage of scholarship there was always the highest percentage visual defects.

"This subject is now receiving much attention at the hands of boards of health, boards of education, pedagogs and parents, but even yet not as much as its importance merits."

MEDICAL PROGRESS

A Century's Progress.—At the centenary meeting of the British Medical Association held in London in July, Lord Dawson of Penn delivered the President's address, entitled "One Hundred Years and After," in which he compared the condition of medicine and the sanitary problems existing in 1832 with those of the present year and noted the astonishing progress made in the closing decades of the nineteenth century and the first three of the present one. Before cataloguing these discoveries he commented upon the strange scepticism which has always retarded the acceptance of new truths. The discovery of the spirillum of relapsing fever in 1873 and that of the malarial parasite in 1880 were made many years before their significance was appreciated by the medical world. Again the history of anesthesia affords a striking example of how long truth may remain unheeded. The anesthetic properties of nitrous oxide, the speaker said, were discovered by Humphry Davy in 1800 and those of ether by Faraday in 1818, yet it was not until 1844 that surgical anesthesia was—not discovered but — accepted by the medical world. A generation of disciples bred in its methods was needed to bring Lister's teaching to fruition. The reaction at last to this discovery exemplified the other tendency of medicine to rush ahead once it has grasped the significance of any advance. Surgical craft bounded ahead with an exuberance which was at times forgetful of physiology and wider clinical considerations. Surgery's possibilities are not yet exhausted and it still has large fields in the domain of the thorax, the arteries, the nervous system, and the ductless glands. In the present century physics and chemistry linked with physiology have taken pride of place in their services to medical knowledge. Biochemistry gives us the means of quantitative assessment, and organic chemistry has given us the active principles of crude drugs and thereby aided us in therapeutic precision and has also given us various anodynes, sedatives, and hypnotics, as well as truly specific remedies and powerful antiseptics. Other discoveries of vast importance to medicine and the welfare of the human race are those of the ultraviolet rays (artificial sunlight), vitamins, hormones, the virus diseases, etc. The pathogens of this latter class of diseases, filtrable and invisible under the most powerful microscope, have now been photographed and measured by means of ultraviolet rays and the use of quartz instead of glass in our instruments. In concluding his address the speaker exclaimed on the greatness of the panorama which has presented itself during the life of the British Medical Association, and said that never before had there

been greater promise that the advancing front of knowledge would "make one music as before, but vaster."—*British Medical Journal*, July 30, 1932.

Cancerous Degeneration of Gastric Ulcers.—L. Bouchut and M. Levrat discuss this question in the *Journal de Médecine de Lyon*, August 5, 1932. It has been studied for a long period without any definite result, the reason for the divergence of views being the difficulty of diagnosis—whether it is a case of carcinomatous degeneration of an ulcer or one of cancer of slow evolution of ulcerative type. The arguments based on histology, gastric chemism, and symptomatology are, for the reason mentioned, of only relative value. The authors think that the criterion least subject to criticism exists in the duration of the evolution of the ulcerative syndrome. A cancer of ulcerative type reaches its term in five or six years at the maximum, whereas the carcinomatous ulcer progresses more slowly, and the authors believe that when the ulcer-cancer syndrome has lasted more than ten years the conclusion may be reached that the case is one of cancer grafted on an ulcer. From a study of 144 cases of cancer of the stomach and 106 cases of gastric ulcer the writers conclude that carcinomatous ulcer is quite rare while slowly progressive cancer of ulcerative type is relatively frequent. This is a matter, they hold, not simply of theoretical interest, but one that should be taken into consideration in weighing the indications for gastrectomy in a given case of ulcer of the stomach.

The Menace of Obesity.—Ernest Bulmer, writing on this subject in the *British Medical Journal* of June 4, 1932, says that body weight is an important factor in longevity, overweight after the age of 38 tending to shorten life. The weight after childhood represents the balance of two factors—the quantity of food ingested and the expenditure of energy in maintaining body heat and in glandular and muscular activity. The controlling mechanism is asserted by Grafe and Grünthal to be localized in the hypothalamic region. The obesity noted in persons who consume an inordinate amount of carbohydrates is assumed by Shui and Gordon to be due to hyperinsulinemia resulting from overstimulation of the pancreas by the starches and sugars. The increased mortality is due largely to diabetes associated with obesity, and also in some measure to the increased blood pressure which is found in the overfat. Degenerative diseases of the heart, arteries, kidneys, and liver which are

frequent in overweights terminate fatally between two and three times more often in the obese than in those of standard weight, and over three times more often than in those of underweight. Chronic cholecystitis and gallstones are also much more frequent in those of overweight. In the treatment of obesity the cooperation of the patient is absolutely essential. In the matter of diet the aim is to reduce the intake about 20 per cent below the needs of a person of the same age and of standard weight. Easily assimilable carbohydrates are replaced by bulky foods of low calory but high satiety value, the ideal being to use standard diets of 1,000 to 1,200 calories per diem. Increased exercise may be prescribed, but with caution. When the arteries are supple cold baths, which strongly stimulate metabolism, are advisable. Endocrine treatment may be resorted to when indicated. Thyroid may be tried in constitutional obesity, but it should not be forgotten that the main indication for this therapy is myxedema rather than obesity.

Phrenicectomy vs. Pneumothorax.—Weck and Bachmann, writing in the *Journal de Médecine de Lyon* of June 5, 1932, discuss the relative merits of these two measures in the so-called collapse therapy of pulmonary tuberculosis. The former has of late been gaining favor in the estimation of many phthisiologists but has not yet become the operation of choice. The authors think the operation has not had time to establish itself firmly as a legitimate therapeutic measure. It has the advantage of being performed once and for all and does not expose the patient to the dangers of repeated operations. The division or excision of a small section of the phrenic nerve is a comparatively simple operation and the patient is usually able to resume his former mode of life in the course of two or three months—a matter of considerable importance to a laborer or a farmer. Bernou of Leyzin, who is an enthusiastic partisan of this operation, has had favorable results in 80 per cent of his cases. The writers, however, are a little doubtful of the justifiability of phrenicectomy in cases in which the tuberculous process is extensive and progressive and not confined to one lung, for the danger of an aggravation of the lesions in the opposite lung, when both sides are affected, is very great.

The So-called Dry Bronchiectasis.—Bengt Ihre says that an abundant expectoration is usually, but he implies erroneously, regarded as a characteristic feature of bronchiectasis. This no doubt is the classical clinical picture,

but what makes it so is the *complicating* bronchitis, and if there is no inflammation of the bronchial mucous membrane with copious secretion there is no reason why bronchiectasis should give rise to any symptoms or be detected except at autopsy or in the roentgen picture of the thorax. Bezançon and Reinberg, indeed, maintain that dry bronchiectasis is the true uncomplicated condition, possibly later being complicated with a bronchitis with copious expectoration, assuming then the classical form. The author considers it a mistake to regard all cases of latent bronchiectasis as due to some congenital malformation or to pulmonary debility. In a few cases, of course, this might be true, but as a rule impossible to verify even patho-anatomically; in other cases, however, one may with a fair amount of probability connect their production and development with past affections of the lungs. The author reports three cases of dry bronchiectasis, in two of which there were evidences of tuberculosis.—*Acta Medica Scandinavica*, May 28, 1932.

Hemophilia: The Anaphylactic Treatment of Acute Emergencies by Passive Sensitization.—R. Cannon Eley reports a case which confirms the observations of Mills concerning the value of passive sensitization in the treatment of acute emergencies in patients suffering from hemophilia who have not previously been rendered sensitive to horse serum or to some other antigen. The patient, who gave a personal and family history of hemophilia, was admitted to the hospital in a critical condition as a result of continuous bleeding from an ulceration on the gingival mucosa. The extravasated blood had extended into the tissues of the face, neck and anterior chest wall, from the clavicles to the costal margin. The red blood cells numbered only 1,000,000 with hemoglobin 35 per cent. The intradermal injection of horse serum was not followed by wheal formation. A transfusion was then given, using a donor sensitive to horse serum. Within twenty minutes a typical wheal appeared at the site of the previously injected horse serum, and there was a coincident reduction in the coagulation time of the blood, from 3 hours and 30 minutes to 45 minutes, and at the end of 48 hours it had been further reduced to 12 minutes. It was necessary to repeat the injections at fourteen-day intervals in order to maintain the allergic state and the resultant reduction in the coagulation time. Six months after the patient's discharge he continued to be entirely free from hemorrhage, although he had sustained lacerations during the period.—*New England Journal of Medicine*, May 12, 1932, ccvi, 19.

Raynaud's Disease.—Sir Thomas Lewis, writing in the *British Medical Journal* of July 28, 1932, discards Raynaud's theory of a sympathetic nervous causation occurring through irritability of vasomotor centers, and advances his own theory that the local circulatory disturbance is due solely to the action of cold. In a typical case, he says, the events are as follows, the hands being at rest: The digital arteries already constricted in response to cold, become closed and the circulation in the fingers ceases. Cyanosis appears gradually and is usually but slight, the fingers being faintly violaceous. The arterial spasm continuing, the small vessels of the skin also close spasmodically and the fingers become completely blanched. This secondary spasm with its blanching of the skin, however, is not an integral part of the attack, but is a simple consequence of loss of circulation in the fingers. Another consequence of the loss of circulation is numbness. As the attack begins to subside the fingers acquire a deep violet tint, and when the blood again circulates freely there is a reactive hyperemia and the fingers become bright red in color and tingle. It is to be noted that in the attack the fingers show discoloration first of all in their tips, due to the fact that the digital arteries at first contract to obliteration near their termination, the obliterative spasm spreading gradually up the vessels of the fingers. When the attacks are very easily and frequently provoked, small areas of necrosis may appear at the finger tips. Raynaud's theory of the causation of these attacks, as above stated, was that the loss of circulation in the affected parts happened through sympathetic nervous influences and was due to irritability of the vasomotor centers. In opposition to this Lewis says that recent observations have shown that spasm of the vessels of the fingers in Raynaud's disease begins in the tips of the fingers and thence spreads to their bases and even to the hands. But when vasoconstriction is brought about through the sympathetic nervous system the vessels appear to contract simultaneously in all the territory involved, and there is no evidence of an orderly progression from the periphery to the center. Recent observations have shown that the vessels of the fingers in Raynaud's disease can be brought to a state of spasm by purely local cooling and that the digital arteries can be brought into complete spasm quite locally over any short stretch of their course through the fingers. The orderly manner in which the fingers are involved when the patient is exposed to a cold atmosphere is due merely to the fact that the fingers cool first at their tips and later at their bases. It is not abnormal, Lewis says,

for digital vessels to contract in response to exposure of the body to a cold atmosphere, but what is abnormal is that they should then close completely. The latter is probably due to a structural abnormality in the vessels, namely a thickening of the intima. Raynaud's disease is therefore a local disease of the arteries and is not caused by a disturbance of the vasomotor nervous system.

Certain Syndromes Associated with Arterial Hypertension.—Soma Weiss says that while the bearing of arterial hypertension on vascular disorders in general and on degenerative diseases of the brain, heart, and kidneys in particular has been sufficiently emphasized in recent years, it would seem to be in order to call attention to certain syndromes that occur frequently at a relatively early stage of hypertension. Among the early symptomatic manifestations of arterial hypertension the most frequent are those referable to the central nervous system. Among the symptoms directly referable to this system are headache, dizziness, nervousness, tinnitus aurium, insomnia, hot flashes, throbbing, and fainting spells, alone or in combination. It is probable that these phenomena are secondary to a relatively unstable vasomotor regulation of the cerebral circulation. Various vasomotor responses of the cerebral blood vessels, even in the presence of normal blood pressure, are great as compared with other vascular areas of the body and are of course accentuated in the presence of high blood pressure. Some patients with fluctuating blood pressure can estimate the height of their hypertension by the intensity of their symptoms, such as tinnitus. There is sometimes an alteration in the personal characteristics, but the role of the personality is more often a casual one, consisting in an overactivity, worry, a meticulous attention to details, etc. A comparatively infrequent but diagnostically very important syndrome is a cerebral vascular crisis. The onset is usually sudden, increasingly severe headache develops, often with confusion and drowsiness, and sometimes with impairment of vision, convulsions, or temporary palsy of the extremities. These manifestations may last for hours or days and in some cases probably cause death. There is a remarkable parallelism between this syndrome and the manifestations of brain tumor. When the question of diagnosis arises it may be remembered that the weight of probability is on the side of cerebral crisis when there are in the eyegrounds narrow arteries, tortuous small veins, hemorrhages, and white scars. Furthermore greatly elevated blood pressure, especially diastolic, seldom develops secondarily to brain tumor. Cerebral

hemorrhages in arterial hypertension are not infrequently preceded by certain symptoms. There may be a sudden change of personality with mental depression and a slowing down of motor and sensory functions. Some patients may even develop manic tendencies. Periodic severe headaches, often with radiation toward the occipital area may occur months before the onset of hemorrhage. Amnesia, disorientation, double vision or disturbed vision with lack of association and power of coordination in hypertensive subjects may presage a cerebral hemorrhage. Various other bizarre manifestations, be among the prodromal symptoms suggest, and increased tonus of the sympathetic nervous system with a decrease of that of the autonomic system. Severe epistaxis and pulmonary hemorrhage may occur as a result of arterial hypertension. Among the symptoms preceding circulatory failure in early hypertension is precordial pain, palpitation is frequently present without any evidence of myocardial failure, and also simple arrhythmia and premature atricular and ventricular contractions. Nocturnal nervousness and cough and paroxysmal dyspnea are also suggestive of hypertension. Spasmodic contraction of the arteries with symptoms recalling Raynaud's disease are sometimes present in addition to intermittent claudication. Finally patients with arterial hypertension quite frequently have hyperglycemia with or without glycosuria. Arteriosclerosis may develop secondarily to diabetes, but disturbances of the carbohydrate metabolism may also develop secondarily to arterial tension.—*The New England Journal of Medicine*, July 28, 1932

Abdominal Symptoms in Manifest Heart Disease—Emmet F. Horne and Morris M. Weiss recall the old clinical maxim "When the patient complains of his stomach, think of his heart," and add that the opposite is also to be admitted, both of them stressing the close relationship, anatomical and physiological, of these two organs. Their paper dwells upon certain special symptoms and problems which are encountered in manifest heart disease but which may primarily attract the attention of the gastroenterologist. The frequent coincidence of disease of the gall bladder and of the heart has attracted the attention of clinicians, but while the former may reflexly cause disturbance of the cardiac rhythm it cannot produce organic heart disease. Thrombosis of a branch of the right coronary artery may simulate very closely the so-called "acute abdomen." Jaundice occurs in cases of congestive

heart failure and is a frequent accompaniment of pulmonary infarction resulting from cardiac disease, but a satisfactory explanation for the pathogenesis of the jaundice in these cases is not yet forthcoming. Various disturbances of cardiac rhythm of neurogenic nature may result from gastroenteric disease. Finally dysphagia in patients with heart disease may result from compression of the esophagus due to various causes—aneurysm of the aorta, an enlarged left atrium, or congenital anomaly of the great vessels. The difficulty in swallowing resulting from pressure on the esophagus by the enlarged left auricle is often progressive when this enlargement occurs as a consequence of mitral stenosis.—*Southern Medical Journal*, July, 1932

The Glove Bath—Writing in the *British Medical Journal* of July 16, 1932, Matthew B. Ray describes a procedure which he has found very useful in the treatment of so called rheumatic troubles of the extremities. In the treatment of pain and stiffness associated with rheumatic and other conditions of the hands and feet, he says, the application of heat by means of hot air, vapor, paraffin wax, mud, electric radiation, or diathermy is usually adopted. As practically all these measures require some kind of special apparatus, which is not always available, he has found good results can be obtained by a simple and easily applied method which can be carried out wherever there is a supply of running hot water. The hands, enclosed in rubber gloves a few sizes too large, or the feet encased in rubber socks that reach half way up the calf, are immersed in hot water maintained at a temperature of from 105° to 110° F for twenty to thirty minutes every day or every other day. If desired an ointment of methyl salicylate, iodine, or menthol can be applied to the parts before putting on the gloves or socks. Owing to the retention of heat and the raising of the local internal temperature, it will be found that the hands and feet, on removing the coverings are bathed in a copious perspiration and are more supple. Massage can therefore be much more efficiently carried out as all muscular spasm is relieved. Among the many indications for the use of what the author calls the "glove bath" may be mentioned arthritic changes with stiffness, pain, swelling, or deformity in the wrists, ankles, hands, or feet, sprains and strains of the ankles or wrists, stiffness following old injuries, fibrositis of the palm or plantar fascia, in the manipulative treatment of flat foot where muscular relaxation is required, or in any condition in which pain and stiffness are prominent symptoms.

LEGAL

MALPRACTICE—LEGAL STANDARD IN CIVIL ACTION AGAINST UNLAWFUL PRACTITIONERS

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

A situation that is of interest to every physician is that which arises when a person not legally qualified or authorized to practice medicine is sued for malpractice. The situation may arise in the case of the magical healer or equally in the case of the chiropractor. Quite apart from the question of the criminal offense of practicing medicine illegally, the problem for the courts is by what standard shall such person be judged in a civil damage action based upon a claim of malpractice. An analysis of a few of the principal cases will show that a fair rule of law has been laid down by the courts.

In a nearby State, which like New York does not sanction the practice of chiropractic, an action was brought against a man who had been engaged in the practice for several years. The plaintiff, a married woman, had consulted him with regard to complaints of soreness of the neck and back, dizziness, numbness, noises in the head and other vague complaints. The defendant made what he called a chiropractic examination of the patient, consisting of taking the case history, palpation and the finding of the vertebra from the back of the skull to the diaphragm, along the spine. He then purported to explain to her the relation of the spine to the brain, and the various requisites of his proposed "treatment." She consented to his conditions and the chiropractor undertook to treat her. The particular "treatment" or "adjustment" involved in the case was described as follows: "By his direction she knelt on a pillow with her chest against another pillow on a chair and her head sideways, 'that position rendering the spine in a horizontal position.' Then the defendant 'took his right hand over his left and held it an inch or two above her neck, and came right down on her neck with all the heft he could put on it.'"

The defendant told her that if she did not feel better the next day she should go to a doctor, for if she did not improve, chiropractic treatment could not help her. She did very shortly consult a regularly licensed doctor and x-rays taken revealed a fracture of the transverse process of the second cervical vertebra of the right side. A plaster cast was applied to her neck and her injuries thereafter were given proper treatment by a qualified physician.

In the action which she brought against the chiropractor, the patient made the claim in her

complaint that he had held himself out as competent to treat her as a physician, but that he had treated her in so unskillful and careless a manner that she had suffered severe pain and injuries.

On the trial of the case the defendant sought to introduce evidence that he had possessed and exercised in his treatment the usual degree of care, learning and skill ordinarily used by the chiropractors in that community. The judge ruled that the said testimony was inadmissible, and in charging the jury stated in part: "That if this defendant was unlicensed to practice medicine . . . he cannot escape responsibility for any negligence such as I will describe in a few minutes by showing that he called himself a chiropractor rather than a physician, by showing that his system of treatment had a distinctive name—chiropractic—or by showing that he and the patient entered into a contract for the use and receipt of this particular system of treatment. That is, if he undertakes to practice medicine, and he does so contrary to the law, he cannot escape civil responsibility for negligence, such negligence as a physician would be held for, by pleading either that he was not a physician or that he made a contract to treat the patient according to a distinctive system not recognized by the profession of medicine. . . . So when this defendant undertook to apply medical treatment, if he did undertake to apply medical treatment, there was an implied undertaking on his part that he had, and would bring to the performance of his undertaking, not only due care and skill, but that degree of skill and capacity ordinarily possessed by the duly licensed and competent physician of average skill and ability in his locality. That is, the degree of care and skill required of him is not to be ascertained and determined by ascertaining what degree of care and skill a chiropractor might exercise. He is held up, as I construe the law, as I instruct you, to the degree of skill and ability which the physician or ordinary ability and the physician of ordinary experience possessed in his locality."

The jury brought in a verdict for the plaintiff and an appeal was taken. The appellate court approved the instructions which the trial judge had given, as above quoted. The appellate court made clear its attitude toward chiropractic treatment, stating:

defendant in his treatment of the ailment plaintiff was exercising his calling as a doctor in a matter within the field of medical surgery, and while so acting was not any of the exempted schools, classes, or situations enumerated and described in § 76 (the statute in point). His acts therefore were unlawful, as would be like acts of any other members of the school of medicine or chiropractic.

The unlawful acts of the defendant did not become lawful as between Mrs. W. and himself without her assent to the exercise of such acts on her behalf, or by reason of the alleged fact that a school of medicine justified them by its customs and principles of practice. The understanding of a physician is that he will treat his patient, if he may lawfully do so, according to the system or school which he professes or follows, and that he will use due care and skill according to the practice of that system or school of medicine in the community where he practices his profession. The purpose of the Legislature in enacting the statute before us was not to provide a penalty for its violation but to protect the public from ignorant and incompetent practitioners. The statute therefore should be construed as intended to afford relief by awarding damages to all persons suffering harm from the violation of the statute is the proximate cause of their injuries."

This case is similar to one that was decided in the northwestern States nearly half a century ago. In that case a fifteen year-old boy was diseased with some disease of the hip, and his mother took him to a so called clairvoyant "physician." The said "physician" undertook to diagnose the condition by going into a sort of trance, while in that state to give his diagnosis and prescribe for the ailment so disclosed. He made a physical examination of the patient and obtained no history of the case. The result was that the clairvoyant diagnosed as rheumatism a case of a disease of the hip joint.

The case was brought to recover for malpractice, and the defendant claimed that he was entitled to be judged by the ordinary skill and knowledge of a clairvoyant system. The appellate court, however, decided that he was to be judged according to the ordinary skill and knowledge of physicians in good standing practicing in that community.

In another similar case that arose recently involving a Chinese herb doctor who carried the following advertisement in a newspaper "Dr.

Professional services to the public, and a guarantee of a sure cure for all kinds of diseases, including chronic cases of long standing. No. 10 Main St., Phone 5152."

The patient, who had for many years been suffering from chronic pulmonary tuberculosis, consulted the man. The patient was given a super-

herb examination, the "doctor" looking at his tongue and feeling his pulse, and was asked a few questions. No examination of the lungs was made, and no test of sputum or urine was taken, but the "doctor" promptly advised the patient that the disease was not tuberculosis but a disease of the kidneys. He claimed he could cure the condition, and dosed the patient with herbs from China, forbade the use of eggs, chicken and milk as food, and also ruled out the drinking of cold water. The patient adhered to the treatment for seven months, by which time he had lost twenty-five pounds in weight, his cough had become much worse and his general condition had become frightfully weakened. He then returned to the care of recognized physicians, under whose treatment he partly regained his health.

The patient sued the Chinese doctor for damages in a malpractice action. The defense was set up that the treatment was in accordance with the teachings of the "generation" school of teaching, which the defendant had studied for long periods in China. On the trial he testified as to his experience in treating tuberculosis, but the testimony revealed that he was profoundly ignorant of fundamental matters of medicine and anatomy. The court concluded that he was simply a charlatan, without skill or scientific knowledge, who made it his business to practice upon the ignorant and the unwary for gain. The court refused to countenance his claim that his treatment was proper under the standards of his school of medical learning, and ruled that his liability for damages depended on whether or not he had exercised the care of physicians and surgeons in good standing in the community.

In those States, of course, where chiropractors and others are licensed who practice branches of medicine not recognized in New York State, the result is different. The highest court of one of the Pacific coast States, which legalizes the practice of chiropractic, recently in a malpractice action in which the liability of the defendant was determined, used as a criterion not what competent physicians and surgeons declared to be proper practice, but what chiropractors declared to be their standard of proper practice. The court based its decision in that case on their testimony as to the manner of properly applying pressure to the patient's side and hip "to relieve pressure upon the patient's sciatic nerves at the points of their departure from the spinal column."

The characteristic impertinence and impudence of the quack and the cultist is demonstrated in these cases. Deliberately defying the law they seek to invoke in the civil actions brought against them for malpractice, the standards of their cult. These standards are not only illegal, but also a menace to the public health. Fortunately, the courts have rejected their cowardly plea in this respect, and have justly held them responsible for their unlawful and negligent acts.

CLAIMED NEGLIGENCE BY FAMILY DOCTOR IN TREATING CHILDREN OF DEFENDANT

In this case a physician, at the request of the defendant, called at his home and found his twenty-year-old daughter suffering from scalp burns. The doctor removed the tissue and burned hair with scissors and forceps, and cutting away the good hair for an inch outside the burns, applied a boric acid dressing. This treatment was continued over a period of approximately one month and the patient subsequently discharged by the doctor. When the doctor discharged the patient he warned her, however, not to wash her hair without coming back and consulting him, but the patient disregarding his admonition went to her hairdresser and had her hair washed. After her hair had been washed she returned to the doctor, and he found she had an acute suppurative infection of the burned area, which the doctor treated by opening and draining a number of pus pockets and putting on dressings. Erysipelas subsequently developed, for which the doctor gave erysipelas vaccine and put the patient in a hospital where the patient remained until her scalp had healed.

Shortly thereafter the doctor was again called to the home of the defendant, this time to treat the defendant's son who was suffering from a fractured shoulder bone. The doctor reduced the fracture and put on a Velpeau's splint. He continued to treat the son until the fracture was healed and the boy had full use of his arm.

Sometime after the doctor had completed his treatment, he rendered a bill for services. Upon the failure of the defendant to pay this bill, the doctor directed his attorney to bring legal proceedings for the collection of his bill. The answer which was interposed on behalf of the defendant contained a counterclaim alleging malpractice in the doctor's treatment. On the day when the case appeared on the calendar for trial, however, the defendant's attorney evidently realizing the justness of the doctor's claim for the services he had rendered to the family, consented to withdraw the counterclaim and permitted judgment to be entered in favor of the doctor for the full amount of his bill, thus concluding the case.

ALLEGED FAILURE TO TREAT CHILD'S INJURY PROPERLY

In this case the superintendent of a school called the defendant doctor on the telephone and stated to him that a thirteen-year-old girl student had a sore leg which was apparently neglected, asking the doctor if he would apply a dressing to the child's leg if he sent her to the doctor's office. The superintendent further stated that he would see to it that the father of the child furnish any subsequent treatment which would be necessary.

The child came to the doctor's office and an examination of the leg revealed that it was caked with dried blood and that there was a cut approximately $1\frac{1}{2}$ inches long, just below the knee on the anterior portion of the leg, from which pus was oozing. The girl told the doctor that she had hurt her leg while climbing over a barbed wire fence. While the leg was red, swollen and inflamed, the swelling and inflammation were localized.

The doctor attempted to treat the wound by washing it, but the child complained that it hurt and would not permit him to do anything. He

therefore, covered the wound with a sterile gauze dressing and sent the girl back to the school, at the same time calling up the superintendent and telling him that it was his belief that the child needed medical attention.

This was the only time that the defendant saw the child. Subsequently she was taken to a hospital and a short time thereafter died of tetanus. The parents of the child shortly thereafter instituted legal proceedings against the doctor, in which they claimed that the defendant carelessly and unskillfully treated the injuries of the deceased girl, and that such negligent and careless treatment resulted in a condition which caused her death. The case duly came on for trial, and at the close of the plaintiffs' case a motion was made by counsel representing the doctor to dismiss the case on the ground that plaintiffs had failed to establish the cause of action set forth in the complaint or any other cause of action. This motion was granted by the trial judge, thus terminating the case in favor of the defendant physician.

THE DAILY PRESS

Mr. and Mrs.—

Joe's Nerve Fails Him

From New York Herald Tribune July 21 1932

STRENGTH OF HUMAN HAIR

The New York Sun of September first contains a news item regarding the experiments by Clement R. Brown of the Bureau of Standards, Washington, D. C., undertaken at the request of the American Hair Dressers' Association in order to introduce scientific methods of caring for the hair. The article says:

"Brown found that a single hair will support a weight of approximately a quarter of a pound before breaking. It has a cross section diameter of about nine millionths of an inch.

"Light brown hair tended to be the finest and to have a tensile strength of 33,550 pounds a square inch. Medium brown was recorded considerably thicker and weaker. Dark brown approached the fineness and strength of the light brown.

"An auburn hair was found thicker than a brown one and very much weaker. Blonde hair was somewhat finer and stronger, and red hair tended to be much thicker and a trifle less strong. But there was an entirely different story when it came to determining the point where hair began to stretch. Red hair would not yield until a pull had been applied which was about 53 per cent of the amount required to break it. The strong light brown hair stretched with a pull of only 46 per cent of its holding capacity.

"Gray hair with tensile strength of only about 26,150 pounds a square inch was found weakest.

"Various methods were used to determine the effect of heat on the strength of human hair. One type of test showed that the hair began to lose strength slowly after being subjected to heat of about 212 degrees Fahrenheit up to 392 degrees, after which the loss became much more rapid.

"A woman's hair, Brown concludes, can stand heating up to between 200 and 300 degrees Fahrenheit without appreciably losing strength, but beyond that it becomes progressively weaker with increasing heat until at about 446 degrees the hair loses all its strength.

"Another kind of test showed very little loss of strength up to 320 degrees, after which there was a very rapid decrease, the strength approaching zero at 446 degrees Fahrenheit.

"The result of the experiments, Brown says, disclosed that curling irons heated to about 302 degrees produce a satisfactory curling effect without materially lessening or changing the color of the hair. Even heat as high as 356 degrees, he believes, can be applied for short periods without causing perceptible injury, if the work is done by skilled operators."

MACHINES AND HEALTH

The New York Times of August 31 has the following editorial on the effect of machines on employment and health:

"In the New York cloak and suit industry it has just been settled by agreement that employers who make use of electrically operated pressing machines shall pay \$8 weekly for every machine into a fund for the relief of unemployed

pressers. This reads very like the ancient law of deodand by which any inanimate object which has been accidentally the cause of a man's death is forfeited to the crown for pious uses. A wagon that killed a man was confiscated and sold and the proceeds were distributed in alms. The electric ironing machine which has presumably thrown several human persons out of work

would thus seem to be compelled to make restitution. This incident in the New York clothing trade is sure to become a popular item in the indictment against the Machine. It would so well show the essential nature of the Machine as a menace to human values and human welfare.

"There is another side. In the same agreement that assessed the sum of \$8 a week against the Machine its operators were granted a raise of \$12 a week. If the Machine is deodand in depriving some workers of their livelihood, it gives a better livelihood to other workers. Do the victims exceed the beneficiaries? That is the contention in the usual plaint about "Technological Unemployment." The Machine works for increased idleness. Yet it has been repeatedly shown that over a long period the Machine does not destroy employment, but creates it.

"In this economic storm that we are now living through, many discern the break-down of our Machine Civilization. But that is to see only the short-time evil and forget the long-time good.

We see the millions of unemployed and forget the hundreds of millions to whom the Machine has given employment. We see the privation of the moment and forget the steady betterment through the years. Why, after three years of severe unemployment, do the health figures everywhere in the industrial countries show no decline? Why, in the face of such vast unemployment, do these countries exhibit a freedom from serious social unrest that is nothing short of extraordinary? The level of existence for the working masses has been so greatly raised by the Machine that they are able to bear up, body and mind, even under today's distresses. The current death-rate for children in New York is the lowest on record after three years of depression, because through preceding years our Machine Civilization had provided increasingly better food, housing, care and recreation for the children of the masses. The lowest infant death-rate in New York City is in Brownsville, Brooklyn, where many clothes pressers live."

A HALF CENTURY OF PRACTICE

The County Medical Societies of New York State often celebrate the completion of fifty years of practice by their members; but Dr. S. T. Shelly, of Mulvane, a village of a thousand people in Sumner County, Kansas, has achieved entrance into the editorial page of the New York *Herald Tribune* of August 27 because of his originality in holding a reunion of all the babies that he had ushered into the world, as is told in the following editorial:

"Congress would not go far wrong if it voted a special medal to Dr. S. T. Shelly, of Mulvane, Kan. Dr. Shelly is one of an almost extinct, though admirable, species, the country doctor of the '80s and '90s. Not content to retire at the age of seventy-six without something to crown an active career, Dr. Shelly invited the forty-five hundred-odd "babies" he had brought into the world to a get-together reception in Mulvane. A thousand responded, one all the way from Florida.

"The country doctor served the nation. And what an admirable figure he was! His life was dedicated to humanity in rain or snow, sleet or hail, often over almost impassable country roads

in buggy or sleigh or on horseback to win through and save life or usher it into the world. Often he performed emergency operations on some farmer's kitchen table, lacking a better anesthetist than an unskilled member of the victim's family. Known always as "Doc," he pulled teeth and mixed his own medicines. His tonics and purges were dispensed at inclusive rates from bottles on shelves in his office. Prescriptions were for city doctors. His black medicine case went with him everywhere, and with its contents he threw in a bedside philosophy which made him a family friend and counselor. And rarely did he pass from their life with more than half of his fees collected.

"The old general practitioner of the countryside is almost gone today, and with him the yeoman farmer and folk he lived to save. The nation has changed. The automobile, the cement road, the hospital within easy reach, by their use have done their work.

"Dr. Shelly, of Mulvane, Kan., probably knew this when he invited his wards back from whence they had flown in a modern age of travel. All honor to the passing clan—the country doctor."

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

THE EXPECTANT MOTHER'S HANDBOOK. By **FREDERICK C. IRVING, M.D.** 16mo of 199 pages, illustrated. New York, Houghton Mifflin Co., 1932. Cloth, \$1.75.

PAIN IN THE PLEURA PERICARDIUM AND PERITONEUM. A Clinical Study. By **JOSEPH A. CAPPS, M.D.** Octavo of 99 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$3.00.

REFLEX ACTIVITY OF THE SPINAL CORD. By **R. S. CREED, D. DENNY-BROWN, J. C. ECCLES, E. G. T. LIDDELL and C. S. SHERRINGTON.** Octavo of 183 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$3.50.

PRINCIPLES OF PREOPERATIVE AND POSTOPERATIVE TREATMENT. By **REGINALD ALEX CUTTING, M.D., C.M., M.A., Ph.D.** Quarto of 812 pages, illustrated. New York, Paul B. Hoeber, Inc., 1932. Cloth, \$10.00. (Hoeber's Surgical Monographs.)

RECENT ADVANCES IN PATHOLOGY. By **GEOFFREY HADFIELD, M.D., F.R.C.P., and LAWRENCE P. GARROD, M.A., M.B., B.Ch., M.R.C.P.** Octavo of 390 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1932. Cloth, \$3.50.

MEDICINE AND THE STATE. By **SIR ARTHUR NEWSHOLME, K.C.B., M.D., F.R.C.P.** Octavo of 295 pages. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$3.50.

MANUAL OF CLINICAL AND LABORATORY TECHNIC. By **HIRAM B. WEISS, A.B., M.D., F.A.C.P., and RAPHAEL ISAACS, A.M., M.D., F.A.C.P.** Fourth edition. 12mo of 117 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$1.50.

MINOR SURGERY OF THE URINARY TRACT. By **HERMAN C. BUMPUS, JR., Ph.B., M.D., M.S. in Urology, F.A.C.S.** Octavo of 124 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$3.00.

THE SURGICAL CLINICS OF NORTH AMERICA. Vol. 12, No. 3. (Lahey Clinic Number.) Published every other month by W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): cloth, \$16.00, paper, \$12.00.

MATERIA MEDICA PHARMACOLOGY THERAPEUTICS AND PRESCRIPTION WRITING. By **WALTER A. BASTDO, Ph.G., M.D., Sc.D., F.A.C.P.** Third edition. Octavo of 739 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$6.50.

A MANUAL OF PHARMACOLOGY. By **TORALD SOLLMANN, M.D.** Fourth edition. Octavo of 1237 pages. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$7.50.

ELECTROSURGERY. By **HOWARD A. KELLY, M.D., LL.D., and GRANT E. WARD, M.D.** Quarto of 305 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$7.00.

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION. Vol. 23, 1931. Edited by **MRS. MAUD H. MCLLISH-WILSON and RICHARD M. HEWITT, M.D.** Octavo of 1,231 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$13.00.

THE CHEMISTRY OF TUBERCULOSIS. By **H. GIDEON WELLS, M.D., Ph.D., and ESMOND R. LONG, M.D., Ph.D.** Second edition, revised. Octavo of 481 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$7.00.

QUANTITATIVE CLINICAL CHEMISTRY. By **JOHN P. PETERS, M.D., M.A., and DONALD D. VAN SLYKE, Ph.D., Sc.D.** Vol. 2, Methods. Octavo of 957 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$10.00.

ACCIDENTS, NEUROSES AND COMPENSATION. By **JAMES H. HUDDLESON, M.D.** Octavo of 256 pages. Baltimore, The Williams & Wilkins Company, 1932. Cloth, \$4.00.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 16, No. 1, July, 1932. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): cloth, \$16.00 net, paper, \$12.00 net.

THE SIGN OF BABINSKI. A Study of the Evolution of Cortical Dominance in Primates. By **JOHN F. FULTON and ALLEN D. KELLER.** Quarto of 165 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1932. Cloth, \$5.00.

THE HEART RATE. By **ERNST P. BOAS, M.D., and ERNST F. GOLDSCHMIDT, Ph.D.** Octavo of 166 pages, illustrated. Springfield, Ill., Charles C. Thomas, 1932. Cloth, \$3.50.

THE ANATOMY OF THE HUMAN ORBIT. By **S. ERNEST WHITNALL, M.D.** 2nd edition. Octavo of 467 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$6.25.

INDIVIDUALITY OF THE BLOOD in Biology and in Clinical and Forensic Medicine. By **LEONE LATTES.** Octavo of 413 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$7.50.

THE USE OF LIPIODOL IN DIAGNOSIS AND TREATMENT. By **J. A. SICARD and J. FORESTIER.** Octavo of 235 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$4.00.

THE INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioner's Index. Fiftieth Year, 1932. Edited by **CAREY F. COOMBS, M.D., and A. RENDELLE SHORT, M.D.** Octavo of 658 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$6.00.

YOUR TEETH AND THEIR CARE. By **CARL W. ADAMS, D.D.S.** 12mo of 141 pages, illustrated. St. Louis, Mo., C. V. Mosby Company, 1932. Cloth, \$1.25.

AN INTRODUCTION TO DERMATOLOGY. By **RICHARD L. SUTTON, M.D., and RICHARD L. SUTTON, JR., M.D.** Octavo of 565 pages, illustrated. St. Louis, Mo., C. V. Mosby Company, 1932. Cloth, \$5.00.

PRINCIPLES OF CHEMISTRY. By **JOSEPH H. ROE, Ph.D.** 3rd edition. 12mo of 486 pages, illustrated. St. Louis, Mo., C. V. Mosby Company, 1932. Cloth, \$2.50.

BOOK REVIEWS

A SURVEY OF THE MEDICAL FACILITIES OF SAN JOAQUIN COUNTY, CALIFORNIA, 1929. By NATHAN SINAI, D.P.H. Octavo of 214 pages. Chicago, The University of Chicago Press, [c.1931]. Paper, \$1.00. (Publications of the Committee on the Costs of Medical Care: No. 12.)

This is another in the series of medical surveys of various selected areas by the Committee on the Costs of Medical Care.

One finds a description of the location, topography and climate of San Joaquin and a general survey of its medical, hospital, nursing, dental and pharmaceutical facilities. One chapter is devoted to "other practitioners."

In the second part of this book appears a description of three special medical facilities;—first, the tax-supported hospitals, then an extended chapter on the San Joaquin local health district, with the history of its development and tabulations of vital statistics which have been matured under the system.

Finally, a chapter is focused on the new country doctor, which is somewhat more frank in its imaginative fiction than any other part of the book.

F. E. ELLIOTT.

RESISTANCE TO INFECTIOUS DISEASES. An exposition of the biological phenomena underlying the occurrence of infection and the recovery of the animal body from infectious disease, with a consideration of the principles underlying specific diagnosis and therapeutic measures. By HANS ZINSSER, M.D. Fourth edition. Octavo of 651 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, \$7.00.

This work is the outstanding monograph on the subject and with the re-writing of the chapters on phases materially affected by recent researches has been brought up to date. There are additions to the older material of value both to the worker in special branches of the fundamental medical sciences and to the practitioner of medicine.

The value of this work as an educational influence for the practicing physician cannot be over-estimated since it provides the résumé and explanation of infection and resistance to disease on the basis of the closest approach to physico-chemical phenomena. The analysis and personal experience of the author go far to make the cyto-humoral theory of the modern concept of infection and resistance an understandable theme.

As in any other work dealing with the subject there is still the deplorable necessity of employing terminology of ambiguous or controversial character. The statement which Bayliss, the physiologist, made some years ago in reference to immunology still holds good. Until immunology has achieved the same exact basis that physiological chemistry has attained today, the concepts of the science must be couched in defined terms which render discussion of immunological subjects an involved metaphysical exercise. The author has done much to provide an understandable and practical basis for the discussion of the phenomena of resistance and infection.

The book as presented by the publishers is well-made and attractively printed.

EMIL F. KOCH.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 1, July, 1931. (Mayo Clinic Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

That diet plays a decisive part in maintaining health

or in causing disease is well recognized. Certain academic phases of this problem are reviewed in this issue.

Colonic irrigation of ether in an intractable asthmatic attack where other agents had failed is recommended as a reliable means of therapy.

It is not generally recognized that what we regard as an ordinary varicose ulcer of the leg may on further investigation prove to be an arteriovenous fistula. By drawing off some blood from a superficial vein from the affected area we find its oxygen volume content to be much greater than from the vein of a normal area.

It is suggested to short-circuit the ileocecal sphincter in cases which on several examinations show roentgenologic evidences of definite ileal stasis.

EMANUEL KRIMSKY.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 2, September, 1931. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

Oxygen therapy seems to hold sway at the present time as a valuable adjunct in the treatment of pneumonia and other respiratory disorders. One of the contributors has made a study of this problem and finds that "oxygen is of value in pneumonia in so far as it alleviates the attending anoxemia. There seems to be no evidence that it hastens the occurrence of the crisis or shortens the course of the disease" or that the mortality rate is benefited in any way.

One writer has written a painstaking report to show that the injections of small doses of the products of streptococci are very helpful in cases of chronic atrophic and chronic hypertrophic arthritis. Too many diversified remedies have been offered for this discouraging ailment to accept such a report on its face value. Confirmation by other observers will be necessary.

Trichiniasis is an uncommonly diagnosed disease, but certain facts about hogs are here summarized and are worthy of the physician's attention.

In order to definitely establish whether a case is one of Thrombo-angitis Obliterans we find such tests as the histamine, oscillometric, thermocouple, and vasomotor index being used both for diagnosis and as a guide to prognosis. Case reports serve to illustrate the importance of these newer means of examination.

EMANUEL KRIMSKY.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 3, November, 1931. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

A group of splendid case reports and accompanying comments on a number of different conditions. Myelogenous leukemia is amply described and demonstrated. Cutaneous manifestations of acquired syphilis are shown by twenty-five splendid clinical photographs. Doctor Abt shows a few cases of fetal peritonitis. Banti's syndrome is well reviewed and several cases are demonstrated. There are also papers on cardiac lues, gall bladder disease, gastric carcinoma, juvenile hypertension, heart disease and pulmonary pathology, anemia from intestinal flagellates and polyarthritis complicating tonsillitis due to hemolytic streptococcus. The whole volume contains cases one sees more or less frequently and they are written in a very instructive manner.

KENNETH MACINNES.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 4, January, 1932. (Boston Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

This number of the Medical Clinics discusses certain phases of everyday practice that should be of interest to every practitioner. Whether we will choose to agree with everything that is said is another matter. We have in recent months been hearing about unfavorable results of indiscriminate tonsillectomy and are again requested to listen to a few more warmly-expressed opinions as to its benefits—"Tonsillectomy has proved an efficient means of stopping an attack of acute rheumatism where the usual purely medical measures have failed. The operation even in the presence of temperature and inflamed joints is not more dangerous than interval tonsillectomy." Such bold remarks will win friends, and possibly enemies too.

There is a chapter on the ravages of chronic arthritis with a consideration of its contributing causes. Possibly a chapter on the incidence of chronic arthritis in persons who have no discernible contributing factors might also be of interest. The comparative evaluation of X-Ray, iodine, and operation in the treatment of Graves' disease is well discussed. The part that rest alone plays in the course of that disease is, however, omitted. Diabetes insipidus is well discussed, and its intranasal therapy is encouragingly brought to the reader's attention with some explicit advice that should be filed away. Then there is a simple regimen for the treatment of non-diabetic malnutrition in adults by means of insulin.

EMANUEL KRIMSKY.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 5, March, 1932. (New York Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

In this issue the article by Dr. Mosenthal should be especially significant to the practitioner because of a radical departure in the routine method of treating chronic nephritis. "The rule that all patients suffering with chronic Bright's disease should have a low protein salt-free diet, should retire from active life, and preferably live in a warm climate is now believed to be a treatment that is not only inadequate to improve or check a diseased process of the kidney, increased blood pressure, secondary anemia, and certain forms of edema, but has on closer investigation been found to augment rather than to ameliorate these abnormal tendencies." If such a well-established procedure is, as Dr. Mosenthal now feels, detrimental it is quite unfortunate that such dangers were not recognized sooner. Let us hope that the newer method of treating chronic nephritis, formerly looked upon as dangerous, will win a more permanent respect. We are now told that "there is only one effective method that has thus far been developed in this connection and that is the feeding of liberal quantities of protein."

There are a number of neurological cases that are well written up and the discussions that follow these reports are stimulating in leading one to appreciate the possibilities that a neurological investigation can offer. The other reports are more or less familiar to the physician but will serve as reminders.

EMANUEL KRIMSKY.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 6, May, 1932. (Mayo Clinic Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, \$16.00 net; paper, \$12.00 net.

This contribution from the Mayo Clinic is somewhat different from the immediate predecessors of this series

in that less emphasis is placed on the ambulatory phases of clinical medicine and more on the hospital angle of it. As such, we read of progressive lipodystrophy, pulmonary calculus, spontaneous rupture of the myocardium, and of other conditions which many of us may never encounter in a lifetime of private practice.

There are, however, a few chapters that should win the attention of the practitioner. Cod liver has been used in the treatment of pernicious anemia with results that are quite as successful as from the liver of vertebrates. Cod liver oil, on the contrary, was found to be ineffective.

Iodine may serve as a diagnostic means in confirming the existence of a true Graves' disease. We are told that "clinical improvement and a fall in the basal metabolic rate following the administration of iodine as a trial measure confirms the diagnosis of exophthalmic goiter."

In a series of cases of stone in the common duct 13% were found to give a negative history of jaundice due, of course, to incomplete obstruction.

EMANUEL KRIMSKY.

THE HUMAN VOICE: ITS CARE AND DEVELOPMENT. By LEON FELDERMAN, M.D. 12mo of 301 pages, illustrated. New York, Henry Holt and Company (c.1931). Cloth, \$2.50.

A review of this book might best be summarized in the words which the author uses in opening the last chapter entitled: Summary. He says: "In this book the author has led the reader through devious, difficult pathways." Devious and difficult indeed if one should scan the headings of some of the chapters. Such titles as Diphtheria, Angioneurotic Edema, Goitre, Headache—an Important Signal, Immunity to Diseases, The Common Cold, and numerous others equally as foreign to the subject of the Human Voice, its care and development. In addition chapters contain material unrelated to their titles while several others are entirely irrelevant. The chapter entitled, Tonsils in Relation to Voice, contains subheadings and allots space to the Lymphatic System of the Head and Neck, and to the Postnasal Space. The chapter on Vasomotor Rhinitis has a section allotted to the Relation of Asthma to Animals. An equally inclusive chapter is the one entitled, Falsetto Voice, which includes subheadings titled: Aphonia, or Loss of Voice, Singers' Nodules, and Pachydermia Laryngitis.

The author had a very good idea when he set out to write his book but he became involved in too many other good ideas. One can say that it represents a pot-pourri of ear, nose and throat information poorly served.

Due credit, however, must be given for the numerous valuable chapters which deal with subjects such as, the Ph of the Blood, the Narcotic Problem, Quacks and Nostrums and others. The author shows evidence of the expenditure of a great deal of effort and hard work in assembling so many phases of so many subjects. It is unfortunate that the title of the book does not properly justify its contents and that the contents of its pages are so unrelated in many instances.

WHEELER AND JACK'S HANDBOOK OF MEDICINE. Ninth edition revised by JOHN HENDERSON, M.D., F.R.P.S. 12mo of 654 pages, illustrated. New York, William Wood & Company, 1932. Flexible cloth, \$4.00.

In this ninth edition, the revisor has brought this volume up to date. So many advances have been made recently in medicine that much of the book has been recast, and the new material incorporated. A careful review of this handy reference book proves it to be all-inclusive upon the subject of medicine in compact form and as formerly, this work will continue to be helpful to many. It seems almost incredible that so much information can be included in such a compact volume.

HENRY M. MOSES.

OUR NEIGHBORS

REFUND OF DUES IN PENNSYLVANIA

A refund of the money of the Medical Society of the State of Pennsylvania to the County Medical Societies is described in the August issue of the Pennsylvania Medical Journal. First is a letter from Dr. W. F. Donaldson, Secretary to the Chairmen of the Public Relations Committees of the County Societies, as follows:

"The Board of Trustees of the Medical Society of the State of Pennsylvania at their December, 1931, meeting authorized a refund, under certain conditions, of 50c per capita (members paid April 1) from the treasury of the State Society to the treasury of any county society whose 1932 Public Relations activities were approved by the Public Relations Committee of our State Society.

"The attached blanks have been prepared to be completed and submitted by the various component societies giving information as outlined in the conditions established by the State Society.

"Medical leadership in a given county undoubtedly depends upon the character of medical service rendered. Accurate knowledge in the possession of the proper representatives of the county medical society regarding existing facilities for such service is essential for the development of service worthy to be credited by the public to the influence of the county medical society.

"When your Committee has completed the county survey, as outlined in the attached sheets, it will have taken an advanced step toward medical leadership in the county. If the survey becomes continuous, and is sufficiently energetic, soon all lay health and social service organizations in the county will turn to the county medical society for guidance in coordinating the effort toward improving the quality and preventing overlapping of the service rendered to the public, and in minimizing pauperization."

The outline blank for the survey covers a page, and is as follows:

1. Hospitals: Name, location, type, beds, ownership.
2. Independent Laboratories: Name, location, type, ownership.
3. Industrial and Lodge Medical Service: Name, location, Non-Medical official in charge.
4. Free, or part pay, or pay dispensaries or clinics: Name, location, type of management.
5. Other organizations offering limited med-

ical service: Name, location, financed by, extent of medical service.

"Discuss character of medical, nursing and social service in connection with all the foregoing; also county medical society representation therein.

"Note any special or unusual characteristics in distribution of medical service in your county.

"Care of indigent patients in county.

"Any merit or defect in any phase of medical service in county.

"Information concerning existence of private group clinics.

"Mention valid complaints coming from either physicians, official or non-official health agencies, or the public regarding any or all phases of medical service in county.

"Evidence that the County Society Official Periodic Publication Constantly Sets Forth the Public Health and Sickness Prevention. Aims of the County Medical Society.

"Enumerate your editor's comments, local contributions, also excerpts from other publications dealing with sickness prevention aims.

"Enumerate letters or articles published since January 1, 1932, at the request of State Society officers or committees.

"Give evidence that your County Society official publication constantly sets forth public health and sickness prevention aims of your society.

"Copy of your publication's mailing list, exclusive of your own members including:

"Leading educators of the county.

"Editors of newspapers of the county.

"Judges and Poor Directors of the county.

"Trustees and Superintendents of hospitals and dispensaries of the county.

"Secretaries of women's and men's clubs of the county.

"Leaders of parent-teacher associations.

"Officers of health and welfare organization; e.g., Red Cross, Public Health Nursing Association, etc.

"Non-member physicians eligible to membership in the county medical society.

"Evidence of Effective Publicity Obtained Since January 1, 1932, Regarding All Medical Society Activities Through Local and County Newspapers by Radio, or by Lectures Before Interested Civic Organizations in County:

"Give name and date of issue of various

It's **QUICK** **ACTION**

PREVENTS DEFORMITIES—

NO antiricketic substance will straighten bones that have become misshapen as the result of rickets. But Mead's Viosterol in Oil 250 D can be depended upon to prevent ricketic deformities. This is not true of all antiricketic agents, many of which are so limited by tolerance or bulk that they cannot be given in quantities sufficient to arrest the ricketic process promptly, with the result that the bones are not adequately calcified to bear weight or muscle-pull and hence become deformed.

A Specific for Rickets

Mead's Viosterol, on the other hand, is capable of terminating the ricketic process in a brief period in virtually every type of case. Thus if given as a prophylactic in requisite dosage it may be expected to prevent not only bowing of the legs but also the more insidious skeletal defects such as malformation of the chest, hypoplastic teeth, and pelvic abnormalities, which may develop unnoticed when less effective vitamin D products are administered.

Especially Indicated for Prematures

Prematures, twins, infants of low birth-weight, and rapidly-growing, full-term infants are especially susceptible to ricketic deformities because of their greater need for calcium and phosphorus. Yet the first three types of infants, due to their small digestive organs, are generally unable to take even the usual dose of cod liver oil, much less increased doses. For them Mead's Viosterol is specific in preventing malformations just as it is in all other types of rickets.

Mead's Viosterol is packed in brown bottles and light-proof cartons to prevent rancidity and deterioration. Unique dropper-stopper is a convenience and avoids waste.

Because of its potency Mead's Viosterol prevents and cures rickets . . . in small dosage . . . without gastric upset . . . quickly . . . before deformity sets in.

newspapers in county containing references to scientific, economic, and community activities of your County and State Societies.

"Estimate total number of lines or columns printed.

"Attach sample clippings, showing name and date of paper.

"Give titles of lectures or instructive talks by representatives of your Committee or Society before interested civic, fraternal or social clubs or societies, mentioning names of latter, and giving dates.

"Give date and subjects of various broadcasts sponsored by your Committee or Society, naming radio station."

Commenting on the survey, the Journal says editorially:

"More or less complete surveys from twenty-three of the sixty-one county societies have been received, displaying in many of these societies, on the part of certain representative members, an astonishing grasp of the situation involved, while in other societies the response may only be said to be encouraging. It is believed that when the Public Relations Committee of the State Society has completed its review of the Surveys submitted and the Board of Trustees has authorized payment of the subsidy to the treasury of approved societies, then and only then will many members of the component societies awaken to the absolute need for an active Public Relations Committee in their county society. The results of the Survey in certain counties will be published in this Department, from time to time, in subsequent issues of the Journal, with the hope that thereby inactive societies may be stimulated and active societies be given proper recognition. In the meantime, it will be observed, we predict that the county medical societies qualified for health leadership in their respective counties will assume such position upon the basis of knowledge, experience, and unselfish community leadership."

INDEMNITY INSURANCE IN IOWA

The opinion of the Medico-Legal Committee of the Iowa State Medical Society differs in several important respects from the policy of the Medical Society of the State of New York, as will be seen by the following quotations from the annual report of the Iowa's committee printed in the *Journal of the Iowa State Medical Society* for July, 1932:

"During the year, the Medico-Legal Committee has conferred with the Board of Trustees concerning the advisability of taking blanket practice insurance for such of our members: desire policies issued to them in this way; and: far as we know, no definite decision has as yet

(Continued on page 1093—adv. xiii)

(Continued from page 1092—adv. an)

been made. Our committee has been anxious to conserve the best interests of society members and for the information of all, the following synopsis of the situation is here offered:

"(1) About sixty-five per cent of our members purchase commercial malpractice protection.

"(2) Of the three companies who sell most of this insurance, the Medical Protective Company, of Chicago, holds first place, the United States Fidelity and Guaranty second, and the Aetna third.

"(3) The U. S. F. & G. has made overtures to our society, promising a five or six dollar reduction in their premiums as compared with other companies, if we will purchase from them a master policy, under the conditions of which a given number of our members will purchase their policies.

"(4) Under the U. S. F. & G. master policy, each member will pay premiums direct to the company.

"(5) The above mentioned contract is virtually a promise of a small reduction of the individual premiums in return for the endorsement of the company by our Society.

"(6) As far as our committee has been able to determine, no real advantage will be gained in purchasing so-called blanket insurance aside from a slight reduction in premium costs.

"(7) Judging only by our correspondence with the state medical societies which have purchased blanket malpractice insurance, there has been no prejudicial effect as far as court procedures have been concerned, but very few of our correspondents have carried this type of insurance for any great length of time.

"(8) The Medico-Legal Committee has attempted to approach the situation from a judicial point of view, and its recommendation may be laid down as follows: We believe it best to disregard the slight reduction in malpractice policy premiums for the following reasons:

"(a) In order to prevent growing prejudice against the medical profession as a group, it would seem best to avoid appearance of paternalism and mass resistance against the public.

"(b) Knowledge that a physician is commercially indemnified tempts disgruntled patients to bring suits for malpractice, whereas a physician who quietly and personally purchases his own protection, may not be known to be indemnified.

"(c) The more paternalistic our organization becomes, the greater the ultimate expense of management.

"(d) The purchaser of an indemnity policy, if not satisfied with his protection, can purchase the same from any company which suits his

fancy without feeling obliged to support the company issuing a blanket policy to the Society.

"(e) Iowa physicians have been very fortunate in the past in malpractice affairs, and it has always been a good practice to let well enough alone when all is well. The chief anxiety of the Medico-Legal Committee rests in the fact that we believe it to be ill-advised, for the sake of a few dollars saving per member, to let it be known that we are massing our forces in a defensive campaign against the public."

The report on malpractice cases is as follows:

"We are submitting herewith our annual report of malpractice cases for the year ending April 25, 1932. The report includes all cases brought against the members of the Society whether they have indemnity or not, so far as the same have been reported to us, with the exception of one case in Polk County which has been recently begun against Dr. Pearson and which case is being defended by the United State Fidelity and Guaranty Company.

"During the year seventeen new cases have been begun, twelve cases have been disposed of and twenty-nine cases are still pending. Of the twenty-nine cases now pending, fourteen of them have no indemnity and are being defended at the expense of the Society. Of these fourteen cases four have been begun during the last year and three of them were pending at the date of the arrangement between the Medical Protective Company and the State Medical Society, whereby one-half of the expense of the defense was to be paid by the State Medical Society and one-half by the Medical Protective Company. The total aggregate amount claimed in petitions filed in malpractice cases during the last year is \$180,435.

"Since the organization of the Medical Defense Committee of the State Medical Society 347 cases have been commenced against members of the Society, of which 29 are still pending.

"The total amount claimed in damages to date in all these malpractice cases is \$4,403,440.85.

"Judgments have been obtained against members, aggregating \$63,494.35."

HOUSE OF DELEGATES OF IOWA

The July issue of the *Journal of the Iowa State Medical Society* devotes 47 pages to the minutes of the annual meeting of the House of Delegates held on May 4-6, 1932, in Sioux City. The reports of the officers and committees cover about 40 pages of the minutes.

Secretary's Report: The Secretary reported that a meeting had been held in each of the eleven Councilor Districts. The Secretary also gave a financial report which included a six-page table, listing every check that was drawn on the State Society funds.

NOW!

PRIMARY VITAMIN A

(CAROTENE)

with 1000 TIMES

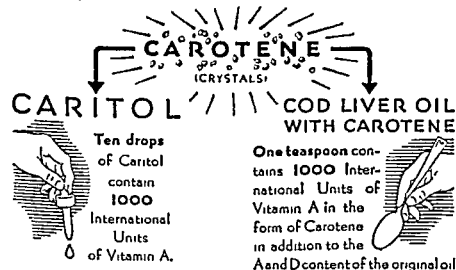

the Potency of
Cod Liver Oil

In Caritol and Smaco Cod Liver Oil with Carotene, physicians now have Primary Vitamin A in two convenient potencies for prescribing

Caritol—Caritol is a 0.3% solution of Carotene in bland oil. It provides a safe, palatable and convenient concentrated solution of Primary Vitamin A (or Pro-Vitamin A) for use wherever Vitamin A, Carotene or both are indicated. The entire absence of all fish flavor from Caritol, and its attractive red color make it especially acceptable to your patients. It is packaged in 15 c.c. dropper top, protectively-colored bottles in special cartons to shield it from the light.

Cod Liver—Smaco Cod Liver Oil with Carotene is a high grade Oil with cod liver oil fortified with crystalline Carotene which Carotene increases its Vitamin A potency 1000 International Units per teaspoon. It provides a most convenient method of ad-

ably improves the flavor. Because of the strong pigmenting properties of Carotene, an attractive clear red color is also imparted to the oil. The color of Smaco Cod Liver Oil with Carotene makes it easily distinguishable from ordinary cod liver oil. It is packed in four-ounce protectively-colored bottles in special cartons to shield it from the light.

Carotene is Fundamental

Carotene is to Vitamin A what sunlight is to Vitamin D therapy. Carotene and sunlight are nature's forms of the fat soluble vitamins A and D. While this has been appreciated for some time in the case of sunlight, the realization was long delayed in the case of Carotene.

FAT SOLUBLE VITAMINS**CAROTENE**
Of VegetablesIs Converted By
CAROTENASE
Of the Liver to Produce**VITAMIN "A"**

Indications

While many cases of Vitamin A deficiency are met with in practice, the average human diet contains enough Vitamin A to meet the minimum requirements of man. However, it is generally admitted that a much higher intake of Vitamin A is required for the maintenance of the highest degree of bodily health and vigor. The need of these higher requirements of Vitamin A for optimum growth and development, for reproduction and lactation, for the development of strong teeth and bones, for healthy resistance against spontaneous infection, and its intimate association with the blood is generally conceded. Therefore, we believe that the intelligent prescription of the appropriate form of Vitamin A to most adults, as well as to infants, young and adolescent children, and especially to gestating and lactating mothers, and in post-operative and anemic cases, is in line with advanced medical practice.

● Both Caritol and Smaco Cod Liver Oil with Carotene, like S M A and other Smaco Products, will be ethically advertised and carefully distributed through prescription pharmacies. No dosages are given to the laity. Each package carries this statement: "Use as prescribed by your Physician."

Public Relations Committee: The Chairman of the Council reported as follows on a Public Relations Committee:

"The Council has taken a forward step in forming a Public Relations Committee, which shall establish sustained working relations with other agencies concerned with related activities. This committee is composed of Dr. W. W. Pearson, Dr. F. P. Winkler, and Dr. J. G. Macrae. The Council feels that this should be a permanent committee of the State Society to maintain harmonious relations with all organizations having a health program.

"The necessity for having a committee of this kind became manifest in connection with the new Bureau of Maternity and Child Hygiene of the State Department of Health. After discussing this matter at two meetings, the Council voted unanimously to cooperate with the State Department of Health because the Commissioner of Health was acting in an ethical manner and seeking medical rather than lay control of this work."

Councilor Districts: The reports of the Eleven Councilors cover nine pages, and contain a wealth of information regarding the county societies.

Managing Director: The Trustees utilized over a page of their report in discussing the duties of the Managing Director, whose employment was made mandatory by the last House of Delegates. A summary of the duties of the Director, who is a layman, is as follows:

"Approximately one-fourth of his time is devoted to some phase of legislative work required by the Committee on Public Policy and Legislation.

"The Managing Director also keeps the county societies informed on the attitude, the activities, and the voting on important medical questions by the respective representatives.

"He is also the liaison officer between the members of the Society and the attorney-general, as well as the law enforcement division of the Department of Health, which has done such effective work against quackery and irregular practice.

"As executive secretary to the Council, he must, in addition to keeping the minutes, acquire contacts through the Public Relations Committee with lay organizations such as the Federation of Women's Clubs, the Parent-Teacher Association, the social workers, etc., so that no program touching medical subjects and relations shall be given without the endorsement of the local medical society.

"He is the executive secretary of the Speaker's Bureau Committee which has won such favorable recognition throughout the state, both lay and medical, as a result of special post-graduate

(Continued on page 1097—adv. xvii)

(Continued from page 1095—adv. xvi)

clinics, radio talks, and public addresses by recognized authorities on medical subjects in the interest of progressive medicine.

"With the Medical Economics Committee, his chief duties have been in securing a satisfactory form of contract for the county societies in their dealings with the boards of supervisors regarding care of the pauper sick. Twenty of these contracts are in force, netting a total sum of over \$60,000.

"The Managing Director is also business manager, assistant editor of the Journal, and secretary to the various state society officers. As business manager, he is responsible for all records, filing and card-index systems, bookkeeping, and the monthly budget sheet.

"Under general service, by his direction, the State Society offices become a clearing-house for information and advice, serving the county societies and their members. Questions by individual members as to what department to approach for help are answered either by citation to some official action by a certain committee or by reference to any officers of that committee for further direction. Aside from these, many miscellaneous questions affecting the board of health, the attorney-general's office, the board of assessment and review, regarding hospital equipment, library, etc., in their relation to taxation, are a few of the many subjects which call for the individual consideration of the Managing Director.

"With a realization of the fact that it is within our delegated authority to appoint the Managing Director and determine his salary, we would not be imperious in these matters, if it is the expressed wish of the House of Delegates that, in the interest of economy and efficiency, his salary be reduced or that he be removed.

"Mindful of the present unreliability of the economic future, it is conceivable that, however desirous the State Society may be to continue the present activities and even the extension of greater ones, it may not be possible to realize them without financial loss. In such an event it is absolutely necessary that some constructive plans be proposed to meet the situation. Shall our activities, wholly or in part, be curtailed or abolished and considered not worth the cost? If only in part, which ones shall be curtailed? Shall the Trustees reduce salaries and not allow traveling and other expenses of special committees? Shall the Board of Trustees draw on our reserve fund to make up any existing deficit? Shall the office of Managing Director be abolished? If so, under what form of management shall the administrative affairs be conducted? By clerical help alone? By the Secretary, with added compensation, or by the Secretary and Editor jointly aided by clerical help?

**COMMITTEE
ON PUBLICATION . .**

(Continued from page 1097—adv. xvii)

"One of the members of the Board of Trustees discussed the employment of a physician as Manager, as follows:

"Personally, and I believe I have the support of the other two members of the Board, I am opposed to the appointment of a physician as Managing Director. By no process of reasoning can I bring myself to see how any successful practitioner, and we would want none other, who might qualify for this particular and important kind of work, could by any method of persuasion be induced to give up his practice for the sum of \$6,000 or less, as has been proposed."

These, and other reports revealed a great activity on the part of the Iowa State Medical Society during the year 1931.

STANDING OF COUNTY SOCIETIES IN OHIO

The August issue of the Ohio State Medical Journal has the following comment inspired by an editorial in the NEW YORK STATE JOURNAL OF MEDICINE of April 1, 1932, page 398:

"Not long ago the editor of the NEW YORK STATE JOURNAL OF MEDICINE asked the members of the medical organization in that state to answer the following questions:

"What do people say about your County Medical Society?

"Do they realize that your society is the advisor of the community in public health matters?

"Do the people turn to the County Medical Society for final advice when lay health organizations propose clinics and consultations and lecture courses?

"Do the people know that your county has a medical society?"

"There is a pertinent suggestion in the foregoing for every county medical society, whether in New York or Ohio or elsewhere.

"It is well for every county society to appraise itself periodically in order to ascertain whether or not it is meeting the requirements expected of it. Self-appraisal frequently discloses hidden weaknesses, whether it be of individuals or organizations. Proper remedies for such disclosures are bound to react favorably, not only to the individual county society but to medical organization generally.

"As a matter of fact, it would be a good idea for every member of medical organization to quiz himself to see if he is devoting sufficient time and effort toward promoting the activities of his local medical society.

"As Dr. A. E. Brant, president of the Mahoning County Medical Society, so aptly said in a

(Continued on page 1099—adv. xix)

(Continued from page 1098—adv. xviii)

recent issue of that society's official publication: "It has been proven without a doubt that nothing can be accomplished without an efficient organization which will function well under any and all conditions. It is apparent, to some extent at least, that we must cast aside our cloak of indifference and respectable aloofness and get into the game. It does no good in isolated groups to air our grievances, rant about injustices, discuss with dismay the question of state medicine and an unappreciative public, unless to blow off steam. It does do good, however, to give these questions real thought, to analyze them honestly and to act constructively even though the benefits we expect may only come several years hence. If we are wrong, let us enter into a program of correction. If the public is wrong, let us educate them. How really can we expect our friends and others to do things for us when we make no attempt ourselves, or not even intelligently inform them? An organization in the business world that wants something goes after it. Why can't we, and still maintain our ideals and self-respect? We can."

BROADCASTING IN RHODE ISLAND

The Committee on Education of the Rhode Island Medical Society has the following report in the August issue of the *Rhode Island Medical Journal*:

"Through the courtesy of the Outlet Company, we were able to run a series of weekly broadcasts, fourteen in number, at approximately 6:10 each Tuesday evening, approximately meaning that the medical speaker and his subject were contingent upon commercial patrons. At the request of the Providence Y.M.C.A., the committee furnished a radio speaker for its vocational talk period, this being limited to a single broadcast.

"While on the subject of radio broadcasting, it might be well to say that the hour set for the five-minute talks over the air by the local station was rather unfortunate, in that while it was a desirable time to reach listeners at the evening meal, the period was also an opportune one for commercial ventures, so that our five-minute period was frequently cut into on either end and the period shortened. The radio station cannot be censured, for this inconvenience as the medical broadcast is gratis, and we are indeed thankful to get our message to the public. A period at noon, when there is not so much commercial aspect and when we could have a ten or fifteen minute period, would be a way out of the difficulty.

"As there were no other means of education to the layman from this body than the radio broadcast, it is suggested that in other years the list of the talks (not the speakers), the time and the radio station be advertised in the *Medical Journal* and the local newspapers."

...and after the operation?

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three-cents each for additional words.

ARLINGTON, New Jersey, 211 Stewart Av.—Attractive 7-room house; plot 120x103; oil burner; 2-car garage; 8 miles from New York City; 5 minutes' walk from station and bus lines; rent \$100 month or sell, easy terms, at a bargain price. Owner, Box 5, Care N. Y. State Journal of Medicine.

Dr. Baer's Diet Prescriptions. 75 diet prescriptions, one for every condition—by accepted authorities—in convenient index filing cases easily accessible—dignified, invaluable—a scientific diet for each patient always at your finger tips—not like an advertisement but smart looking with that personal touch. The whole system, 25 of each diet, 1,875 prescriptions, your name imprinted on each diet, \$40.00. Send check with order. Arnson's Service & Supplies, Main at Linwood, Niagara Falls, N. Y.

FOR SALE—172 Washington Avenue, Albany, N. Y., the residence and office (with separate entrance) of Dr. Clement F. Theisen, recently deceased specialist in diseases of the nose, throat and ear. Instruments and equipment included if desired. Address Clement F. Theisen, Jr., Box 24, Scarborough, N. Y., for further information.

FOR RENT—Doctor's Office. Established for 35 years. Very fully furnished. Sprays dressings, Electricity, etc. Apply Doctor Kenerson, 181 Allen St., Buffalo, N. Y.

WHITE PLAINS, N. Y.

FOR SALE—Nice house, with physician's office, in very center of the city. The practice is 25 years' duration. Exceedingly suitable for young married doctor or dentist, in a growing town. Address Box 33, Care of N. Y. State Journal of Medicine.

VITAMIN A NOW PRODUCED IN CRYSTALLINE FORM

For years, scientists have been exploring vitamin occurrence and behavior, and now Vitamin A has been tracked to its lair and captured.

Physicians have long been able to administer Vitamin B alone in brewers' yeast, Vitamin C alone in orange juice

and tomato juice, Vitamin D alone in irradiated ergosterol.

Now, as a result of patient, careful work of the Research Division of S.M.A. Corporation, it becomes possible to administer Vitamin A alone in Carotene. This Carotene is not derived from fish oil and has no fishy taste.

In crystalline form, Carotene contains one thousand times the Vitamin A potency of cod liver oil. For therapeutic purposes, it is diluted in a bland oil and called Caritol. This is of such strength that ten drops of Caritol contain one thousand International Units of Vitamin A.

S.M.A. Corporation also offers Carotene in cod liver oil of such dilution that one teaspoonful contains one thousand International Vitamin A Units in addition to Vitamins A and D of cod liver oil.

Carotene has hitherto been available in very limited quantities, of less purity, at prices as high as \$11,000.00 a pound. S.M.A. Corporation is now offering crystalline Carotene at prices research laboratories can afford.

Carotene is the primary form of Vitamin A. Sherman and Smith state that the term Vitamin A may (and often does) cover both the "primary" or precursor form (Carotene) and the "secondary" form immediately active in animal nutrition (Vitamin A in the spectrographic sense). For this reason, and because it can be obtained in a state of great purity, Carotene has been adopted as the provisional standard for the biological measurement of Vitamin A potency.

The *Journal of the American Medical Association* reports editorially as follows: "The permanent Standards Commission of the health organization of the League of Nations has been concerned with the problem of vitamin standards and units. . . The Standards thus far selected are as follows: for vitamin A, one International Unit is the potency of 1 gamma (= 0.001 mg.) of pure Carotene, which is converted into Vitamin A in the body."

Carotene is to Vitamin A what sunlight is to Vitamin D therapy. Caro-

COURSE OF FRACTURE TREATMENT 1932

Ten Clinic

Lecture Demonstrations

given by

The New York and Brooklyn
Regional Fracture Committee
of the
American College of Surgeons

A concentrated course embracing the practical application of modern methods of fracture treatment—from October 31 to November 5 inclusive.

Clinics will be given at the following hospitals:

Presbyterian, Harlem, Beekman, Bellevue, Roosevelt, Ruptured and Crippled, Long Island City and Cumberland Street.

Attendance is limited. \$25 is charged for the course.

For further information address

FENWICK BEEKMAN, M.D., Secretary
121 East 60th Street
New York City

tene and sunlight are nature's forms of the fat soluble Vitamins A and D.

Eusterman and Wilbur point out that until recently, the versatility of Vitamin A has apparently not been appreciated, and that a remarkably increasing literature in the last year or two attests its growing importance in the chemistry of food and nutrition, not only in the prevention and cure of certain ailments of man but, when supplied in liberal proportion, in the maintenance of a satisfactory state of nutrition and a high degree of health and vigor, both in the growing child and in the adult. FURTHER EXPERIENCES WITH TRICHOPHYTIN

By LAIRD S. VAN DYCK, M.D., JEROME KINGSBURY, M.D., BINFORD THRONE, M.D.,
AND C. N. MYERS, Ph.D., NEW YORK, N. Y.

From the Stuyvesant Square Hospital, formerly the New York Skin and Cancer Hospital, New York, N. Y.

DURING the past few years considerable interest has developed in regard to the treatment of mycotic infections. A great variety of remedies has been suggested, including x-rays; but unfortunately most of these have no place in the armamentarium concerned with the handling of this disease. The majority of these products are for local application only, and it is our belief that in many of these cases a definite cellular sensitization exists. Our experience has convinced us that where this sensitization is present, local treatment alone is only of temporary value; and that a permanent cure can be obtained only through desensitizing measures.

In a previous article (NEW YORK STATE JOURNAL OF MEDICINE, May 15, 1931, Vol. 31, No. 10, Page 611), Van Dyck and others reported their experiences with Trichophyton Extract in mycotic infections of the skin, both for the diagnosis of sensitization, and also for its therapeutic effect in producing desensitization. In many cases which were refractory to this type of treatment, a complete blood chemical examination, including a glucose tolerance test, sometimes disclosed errors in metabolism which seem to have inhibited the action of the trichophytin; and the correction of these errors enabled the remedy to produce desensitizing effects.

It was felt that the results obtained in the first study justified a continuance of this work. The clinical results, in some instances, were unusually satisfactory; and therefore, after prolonged observations on the original group of one hundred patients, it was decided to make a careful summary of the end results from the therapeutic point of view.

In the previous article a tabulated discussion of the diagnosis, location of lesions, description, duration of infection, results of the test, treatments, duration of treatments and results were presented. It was stated "that recurrences or exacerbations were uniformly seen when the curative injections were not continued until there no

longer appeared any reaction at the site of the injection; or in other words, until a general desensitization had developed." In summarizing these results it was shown that, irrespective of the type of infection, 32 per cent were apparently cured; 28 per cent greatly improved; 21 per cent slightly improved, and 19 per cent unimproved. These results were obtained irrespective of the number of injections and the duration of the infection.

These cases have been called to the clinic and a careful check-up made. It was possible to locate 70 of these cases and it has been found that 93 per cent are free from clinical symptoms and may be regarded as apparently cured. In this group 18 patients had mild recurrences in the form of vesicular and scaly lesions on the hands and feet, from one to six months after stopping treatment. It was universally stated that these recurrences were always milder than the original eruption and responded readily to a few more intradermal treatments with Trichophytin. Three patients were greatly improved and two showed no improvement.

The Trichophytin used in this investigation was prepared according to the method devised by Dr. Walther Scholtz, Director of the University Skin Clinic, Koenigsberg, which consists of a polyvalent extract of the various species of Trichophyton, including *T. gypseum* (40%), *T. cerebriforme* (20%), *T. microides* (10%), *T. rosaceum*, *T. violaceum*, and *T. crassum* (each in equal parts, 20%). The various mycelia are cultured in a suitable media and then dried by heat. The extract of these dried mycelia furnishes the basis for the material used therapeutically and therapeutically.*

The method of treating these patients consisted of intradermal injections of 0.1 cc. of 1% Trichophytin, beginning with one injection at four or five day intervals.

*Trichophyton Extract (Trichophytin) is a product of these investigations.

face of the forearm. Stronger dilutions, such as 1-10, 1-5, 1-2, and 1-1, were given as soon as the previous injection failed to show a positive reaction on observation after 48 hours. For example, if an injection of a dilution, 1-10, gave a strongly positive reaction, the same dilution was used for successive treatments until it failed to produce the reaction. The same procedure was used for each of the other dilutions. When a given dilution failed to give a reaction, the next higher concentration was employed until a concentration of 1-1 was reached. It was very rarely necessary to use the full strength Trichophytin.

It is also most important to be sure that the solution to be injected is perfectly clear in all dilutions, otherwise contamination may be present. If the vials containing the various dilutions are left standing too long in a warm room, decomposition may take place. This also gives a cloudy appearance to the solution. If this liquid is injected intradermally, a pustule may appear at that site, with perhaps subsequent scar formation. It is also important to avoid the use of too much alcohol in sterilizing the needles. Alcohol will tend to precipitate the protein extract.

Plato and Neisser (1902) first had the idea of preparing a trichophytic extract. Bloch perfected the technique of preparing it, and demonstrated by his experiments allergic phenomena of the skin in animals after fungus infections.

Scholtz, 1918, first used intradermal injections of Trichophytin in the treatment of *Tinea Profunda*. His method was to inject 0.1 to 0.2 cc. of Trichophytin into three or four points on the upper arm. He began with a 1-100 dilution, increasing to 1-50, 1-30 and finally 1-10 or 1-5. He also noted that the optimal dilution was that which produced marked local reactions, which is in accord with our observations.

Jadassohn and Peck, 1929, showed that a positive Trichophytin reaction with development of epidermophytids is a frequent occurrence in epidermophytosis of the feet, although the infection in such cases is relatively superficial. In an experimental reproduction of epidermophytosis of the feet, Peck found that the trichophytin reaction became positive 13 days after the beginning of the experiment.

Rosen, Peck and Sobel, 1931, tested 102 persons for hypersensitivity to Trichophytin. They found the intradermal method of testing much more reliable than the Pirquet test or the patch test. Sixty-seven of their cases gave positive reactions to Trichophytin. Examination of the feet showed some of these cases had typical mycotic lesions, and most of the cases showed some scaling and maceration between the toes. Fungi were found microscopically in only nine out of 48 cases examined. Eight of these nine patients showed a positive trichophytin reaction. For comparison they used two brands of Trichophytin, one from

Zurich and one from Hoechst. They found that the Hoechst diluted product (1-50) gave the same degree of reaction as the Zurich Trichophytin in 21 cases tested.

Riecke, 1931, states that the Trichophytin of Hoechst had proved, in his experience, to be the best of all trichophytic extracts in the treatment of *Tinea Barbae*.

In our cases the Hoechst Trichophytin was used exclusively.

Jausion and Sohier, 1929, were the first to report successful results from the use of a "clado-vaccine" in the treatment of superficial mycotic infections.

Ravaut and Longhin, 1931, used "levurine," an extract of various yeasts, both intradermally and intravenously in the treatment of intertrigo with "eczematides" due primarily to a yeast infection. They found that this method of treatment produced first an exacerbation of both the primary and secondary lesions, but later benefited the condition. Using a sample of Levurine, given us by Ravaut, we have treated one such case in our clinic with good results.

Jausion and Sohier, 1930, in a later report on vaccinothrapy of dermatomycoses, mention Plato, Truffi, Bloch, Stein, Scholtz, Fuhs, Rozsabolgyi, Person and Novaki as all having attempted the use of Trichophytin therapeutically, but with doubtful results. They also mention Cranston Low as having criticized its use on the ground that results are uncertain and are obtained at the price of local, focal and general reactions which are often alarming. Our experience with the Trichophytin of Hoechst in more than 200 patients, to whom a total of about 2,000 intradermal injections were given, has failed to produce a single alarming reaction. It is probable that subcutaneous injections would produce severe reactions in many cases, and no one who has tried it, as far as we know, recommends this technic.

The "clado-vaccine" of Jausion and Sohier (1930) is a product of the chemical destruction of cultures of various fungi of the *tinea* group. The cultures were treated first with nitric acid, then boiled, neutralized and filtered. The solution obtained was injected subcutaneously or intramuscularly in doses ranging from 0.5 cc. to 3 cc. at intervals of five days. Ordinarily six injections were given, sometimes twelve. The cases they treated were classified as *Dermatomycoses*, *Mycotic Eczema*, *Parakeratosis psoriasiforme*, *Eczematides pityriasiformes*, and *Trichophytides psoriasiformes et licheniformes*. Out of a total of 45 cases they obtained 36 apparent cures. Nine of the patients were improved, and three had relapses.

The same authors stated that Trichophytin was capable of improving patients slightly, but nevertheless should not be used therapeutically.

They stated that they had seen focal reactivations and slight general reactions following its use, although these incidents were very mild compared to the descriptions of other authors.

The cases of dermatophytosis selected by us for the Trichophytin treatments were, as a rule, the most severe cases that came to the clinic. Mild cases with only slight scaling or maceration between the toes were generally given merely the routine local treatment with Whitfield's ointment iodized alcohol, etc. Most of the cases in our series were told to use nothing locally except boric acid ointment, but occasionally the local treatment had to be varied to give quicker relief. Very acutely inflamed lesions on the hands and feet were treated locally with wet dressings of either boric acid or Burrows' solution.

Since the publication of the first series of 100 cases in May, 1931, a second series of 317 cases has been treated. The results of a typical group are shown in the accompanying table (See Table 1).

A routine blood chemistry analysis was made on every patient of both series. The average blood sugar for the first 100 cases was 106 mgs per 100 cc of blood. The average for the second series was 109 mgs. Variations ranged from a minimum of 84 mgs to a maximum of 159 mgs. The Hastings MacLean method was used for determining the blood sugar, our normal being 90 mgs to 100 mgs.

Among the most interesting of the cases treated was that of a physician who had a very severe tinea infection of the feet with eczematization for three years. Both feet were covered with vesicular and weeping patches which kept his shoes soaked with fluid. He was also subject to hay fever. Having tried every kind of treatment mentioned in the textbooks on dermatology, including a long course of x-ray treatments without getting results, he came to us to be experimented on. A strongly positive trichophytin test was accompanied by a mild flare up of his hay fever. Under treatment with Trichophytin intradermally, every four or five days, he improved steadily, and at the end of three months was discharged cured. A check up six months later found him still cured. He had no recurrence of his tinea in the interval, but had a dermatitis for a few days after wearing a pair of shoes which he had cleaned inside with formaldehyde. This cleared up when he discarded the shoes.

Another patient, a woman aged 45, with vesicular, scaling and hyperkeratotic patches in the hands had been treated for three years by several of the city's leading dermatologists. All the treatments she had received had been local, including every sort of ointment and cream, parasiticide solutions, x-rays to the limit, ultra-violet rays, etc. During the three years her hands had never cleared up even temporarily. The improve-

ment immediately following the trichophytin test was very definite, the test being three plus. The next injections were weaker dilutions, and very little local reaction appeared. The skin lesions likewise showed little further improvement. The patient begged for another strong injection, and was given 0.1 cc of the full strength undiluted Trichophytin. A marked local reaction appeared in 24 hours, and the hands became very much better. At the end of six weeks she was discharged cured, and has had no recurrence in the three months since that time.

One case of fairly severe tinea of the feet developed a typical pompholyx of the palms after the third injection of Trichophytin. A bulla appeared on the forearm at the site of the third injection simultaneously with the appearance of the pompholyx of the palms. Two weeks later the patient's hands, feet and arm showed no apparent lesions, after two more intradermal injections had been given. This case appears to illustrate the laws of both isomorphism and biotropism.

Another case of tinea of the feet was in a patient who had been subject to asthmatic attacks for several years. Following the injection of a 1:50 dilution of the Trichophytin intradermally she had a typical wheezing attack and refused further treatments.

Three of our patients with tinea of the hands and feet and one with tinea of the groin, developed a pityriasis rosea like eruption during or after treatment with Trichophytin. In each case this eruption disappeared within three weeks. The very large percentage of positive Trichophytin tests obtained in a series of cases of pityriasis rosea had led us to examine carefully the feet of those that gave strongly positive tests. Scaling or macerated skin was found between the toes in six out of eight cases examined.

Four cases of lichen planus, which gave positive trichophytin tests, were all found to have evidence of interdigital mycotic infection. One of these patients was also subject to hay fever and another had vernal catarrh of the eyes. These patients have not been treated with Trichophytin, although Jauson, Sohier and Lartigau have reported cases of lichen planus cured by polymycotic vaccines.

Wise and Sulzberger, 1930, reported a case in which a skin test with Trichophytin elicited not only a skin reaction but an attack of violent sneezing and edema of the eyelids and nose which were checked only by the administration of epinephrin. In several cases of our series an urticarial wheal appeared at the site of the injection a few minutes after the test was made, but no violent reactions were observed. Ramirez, 1930, had reported a case of asthma due to tinea. Sulzberger and Kerr, 1930, have reported successful passive transference by means of the blood serum (method of Prausnitz Kustner) in

TABLE I

a case of trichophyten hypersensitiveness of the urticarial type. This would indicate that certain products of pathogenic fungi may be the cause of some asthmas and hay fevers as well as urticarias. The list of possible allergic manifestations that may be attributed to the presence of ringworm infections should also include certain eczematous reactions.

As a rule it was noted in our cases of tinea of the hands and feet that local reactions to the intradermal injection of Trichophyten would gradually diminish unless stronger concentrations were used on successive treatments. On the other hand it was found that if too strong a concentration were injected, a focal reaction might be produced. This may be associated with exacerbation of the itching and occasionally slight malaise. No serious reactions have been observed in any of the cases in this report. Care has been taken to inquire in each case as to whether there was a history of allergic disease such as asthma, hay fever, etc. In cases subject to hay fever or asthma, weaker dilutions were used; usually 1-100 or 1-50. Only one patient had an asthmatic attack as a result of the Trichophyten test, although several of our cases had symptoms of a mild hay fever attack following the preliminary injection. With subsequent injections these attacks usually subsided.

Physiological Explanation of Intradermal Therapy

The investigations of Mueller, 1925, have been carried out with the idea of determining the physiologic basis of resistance and to point to certain organs whose common functions were practically synonymous with resistance.

The functions of resistance are normally inherent in everybody, but during healthy conditions their activities are restricted to a minimum. When infectious conditions prevail evidence of this functional activity becomes apparent, i.e., leukocytes and antibodies are produced.

Experiments of Mueller, 1926, lead to the opinion that the entrance of bacterial excitants in the body causes a reaction involving chiefly two groups of organs:

1. The bone marrow system, which is the originator of the white blood corpuscles and probably the source of the carriers of specific resistance (such as agglutinins).

2. The involuntary nervous system, the conductor not only of the stimulation of the site of the infection to the bone marrow system, but also of the newly formed immunizing substances and leukocytes to the site of the infection.

The vasodilatation by the parasympathetic portion of the involuntary nervous system and the vasoconstriction by its sympathetic portion are, under normal conditions, in that state of regulatory equilibrium that is demanded by the nutri-

tive and functional synergism of the organs. We know of influences of various kinds, acting in the main on the body from without, which disturb this equilibrium by giving a preponderating influence to one or to the other of these two antagonists. Less known to us, however, are the *paths* of stimulation on which these impulses of the involuntary system operate and thus lead to changes in the equilibrium of the blood vessel tonus.

While the described skin stimulation is held in balance by the sympathetic nervous system in all vascular regions, with the exception of the site of injection and of the visceral area, this equilibrium is also missing at the site of inflammation because it is subjected to a constant overbalanced tonus of the local fibers of the parasympathetic nervous system. This overbalance of the parasympathetic tonus is further increased by the sudden stimulation emanating from the skin, and now there occurs the phenomenon that is described above as relating to the increase of leukocytes. The leukocytes in the blood stream are fixed along the walls of the blood vessels, later penetrating the walls and entering the bacterially endangered parts. We are not positive whether this penetration is due to chemotaxis or to impulses inherent in the leukocytes; whichever it may be, the fact remains that they are found in the tissues and in the excretion, where formerly they were absent.

Though leukocytes play an important part in all local processes, connected with infection and inflammation, they are produced in only one organic system, namely, in the bone marrow of the short bones (vertebrae, ribs, skuli) and in the short bones of the hands and feet. In times of great need, as for instance during acute general infections, such as pneumonia, leukocytes are also formed in the long bones of the extremities, which usually contain only fatty tissue. In studying leukocytosis and the activity of individual leukocytes and especially the cause of the appearance of large numbers of leukocytes of the polymorphonuclear type in such infected areas, an interesting problem presented itself. As far as human beings are concerned the well-known old theory of chemotaxis, first established by the botanist Pfeffer, is unsatisfactory. It may be that in test tubes, as well as under the abnormal conditions surrounding experimental work in animals, leukocytes will accumulate around germs, moved by chemotactic processes, but even so the question of the cause of leukocytic migration is not settled as long as the vessels are not injured, as is prerequisite to animal experimentation.

It is astonishing, indeed, that the intradermal injection of a non-irritating albumin does not cause the slightest pathologic change in the cells, and tissues surrounding the site of injection should cause a reaction in the entire circulation. This phenomenon consists not only of a local

change of the leukocytes in the vessels involved by the injection, but of a rearrangement of these cells in the entire circulation. Expressed in numbers, the exact loss of leukocytes to the peripheral circulation and their accumulation in the vessels controlled by the splanchnic nerve reaches from 50 to 75 million; these leukocytes are actually moved from one place to another. In discussing such a migration it must be taken into account that leukocytes are not stationary in the body, but rather that they are continually in circulation and that, normally, they are evenly distributed, an equal number of cells being found in equal amounts of fluid serum. It has been proved experimentally that within a period of one hour the total number of leukocytes does not vary so long as the individual keeps quiet and experiences no physical or mental excitement.

Rationale of Intradermal Therapy

The rationale of intradermic treatment has been firmly established, and it is based on definite scientific principles, viz: antigen-antibody combination and antibody stimulation.

In 1926 two of us (M. and T.) reported results obtained with this method of therapy in Sycosis. Barber and Foreman, 1931, recently reported similar good results in this extremely refractory disease, and they stated that no other method of treatment in their hands gave comparable results. It was their opinion that intradermal therapy was applicable to infections other than staphylococcal, e.g., with streptococci and the higher fungi. Goldsmith, in discussion of Barber's report, raised the question as to whether a positive intradermal test should be interpreted in these cases as evidence of lack of immunity, or of the presence of allergic antibody. His opinion was that there must be some kind of tissue or cell immunity in the skin itself independent of transmissible antibodies.

Scholtz, 1930, states that the employment of intracutaneous injections of very small doses of extremely dilute tuberculin solutions is more effective than subcutaneous injections in the treatment of skin tuberculosis.

Richter, 1930, using as a method of desensitization intradermal injections of specific antigens, has reported success in treating occupational dermatoses and cases of drug sensitization. Our own results with this type of therapy in some cases of occupational eczema, where the specific antigen was discovered, have been extremely satisfactory.

It is our opinion that careful regulation of the diet is a helpful means of assisting in the therapy of mycotic infections. Alleged failures in the use of Trichophytin are largely due to the technic of treatment. Our experiments confirm

the original ideas in regard to the handling of these cases.

Summary

Further investigations on a second series of cases suffering with mycotic-like eruption confirmed our earlier observations that a positive trichophytin test might be obtained in these patients. From these observations it appears that the extract finds ready application in differential diagnostic point of view. The observations are important in establishing the mode of procedure in treating eruptions sometimes closely simulate symptoms of other causes.

Analysis of the therapeutic results indicates that with a small number of treatments very satisfactory clinical findings are obtained. Emphasis is placed on the importance of regularity in treatment and also the necessity of maintaining concentration adequate to produce a local effect. Desensitization can only follow under certain circumstances.

Complicating skin eruptions must be treated on a separate basis. To do this the importance of a complete blood chemistry is urged. Analysis of the clinical findings indicate that at least 50 per cent of patients are apparently cured; 32 per cent are greatly improved; 32 per cent are somewhat improved and 5 per cent unimproved. In the last group, complicating eruptions were observed.

The average number of injections was 10, using a range of concentrations as indicated in the body of the paper. Turbid solutions should not be used under any circumstances for the reason that they are bacterially contaminated and contain alcohol used to sterilize the needle.

A follow-up of the first series of patients reported in 1931 showed that 93 per cent of who returned are now free from clinical eruptions; 26 per cent had mild recurrences and 26 per cent had mild recurrences and were found among the cured cases.

The average blood sugar for 200 cases was 90 mgs. per 100 cc. of blood as compared to 90 mgs. as our normal value (Hastings-McCormack method).

Various manifestations of sensitization to fungi are enumerated.

Results of vaccino-therapy by subcutaneous injections of polymycotic vaccines are summarized from reports of other investigators.

Mueller's explanation of intradermal therapy in general is discussed from the physiological point of view.

An attempt is made to explain the rationale of intradermal therapy as applied to mycotic infections of the skin, tuberculosis of the skin, syphilis, vulgaris and occupational eczema.

RUPTURE OF THE PREGNANT UTERUS AT FULL TERM WITH REPORT OF A CASE*

By FREDERICK W. LESTER, M.D., SENECA FALLS, N. Y.

ONE of the most alarming and distressing accidents that can befall a pregnant woman is rupture of the uterus. That such accidents occur, not rarely, is a matter of common knowledge among obstetricians. In searching the literature for the past ten years, it was possible to pick up references of numerous case reports describing this very dramatic, if not actually spectacular event in the life of the gravid female. The factors concerned in spontaneous rupture of the uterus, and the phenomena observed at the time of such accidents have been faithfully recorded in the standard modern text-books in this country and in Europe, and the actual cases described in various journals devoted to surgery, gynecology and obstetrics. These descriptions are well worth perusal by any who are interested in the subject. The majority of the reports have appeared in German medical literature, especially in those medical periodicals emanating from Berlin. Briefly, the causes to which this accident has been ascribed are as follows:

Causes associated with

1st. Mechanical impediment to passage of the child, as

- a. Transverse presentation.
- b. Pelvic deformity.
- c. Large size of foetus.
- d. Obstruction from fibroid or other tumors.

2nd. Without mechanical impediment to passage of child:

- a. Uterine tissue degenerations, as old Cæsarean section scars of the uterine wall, or other operation scars.
- b. Traumatism, as blows, falls, etc.
- c. Multiple pregnancies and thinning of uterine wall, due to frequent child bearing.

Symptoms:

The symptoms vary as to whether the rupture is complete or incomplete. When complete, rupture usually occurs suddenly and without warning. A sudden, sharp pain occurs in the abdomen, and symptoms of violent shock and collapse, with feeble and frequent pulse or complete absence of the pulse, cold hands and feet, vomiting, etc., supervene. The merest tyro in the art of abdominal examination can detect the physical signs, and a round, hard, movable tumor, the head of the foetus, may be felt by the hand in the mid line of the patient's abdomen, seemingly directly under the skin.

In incomplete rupture, where the peritoneum covering the uterus remains intact, the symptoms are less striking. While the wall of the uterus

may be broken through, the child will not have escaped completely into the abdomen, but will be contained in a stretched pouch of peritoneum of rather indefinite outlines.

It is not the purpose of this paper to enter into any prolonged discussion of the phenomena leading up to rupture of the uterus. Such phenomena are described in detail in every text-book on obstetrics, and are more or less familiar to every practitioner. Suffice it to say that either form of rupture of the uterus, involving any portion of the uterine wall above the cervix uteri, is an accident of the utmost gravity, whether it occurs during the progress of labor in a well conducted hospital or whether it happens to a woman doing her house work on a backwoods farm.

The prognosis depends upon the extent of the rupture, the amount of hemorrhage, the patient's general condition and ability to withstand shock. Formerly, in the older works on obstetrics, it was stated that one out of six cases survived, 83⅓% mortality. Modern surgery, in the treatment of these lamentable accidents, has reduced this terrible maternal mortality to about 26%. The foetal mortality, however, still remains high, it being a rare exception for the child to survive.

The treatment is surgical and requires immediate operation, as a major surgical emergency.

The following report presents some rather unusual features of a case of complete uterine rupture:

Case 1—Helen M.—White—Age 32—Housewife—German parentage. Married twelve years. Two previous Cæsarean sections had been done at full term, and one child was born at eight months naturally. The reason of the previous Cæsarean sections had been that she was a frail, slight woman with a justo minor pelvis.

She was taken ill at 11:00 o'clock A. M., November 9, while working about her house, with a sudden, severe, abdominal pain and vomiting. She was pregnant, and had expected delivery November 15th. Being alone in the house, she lay down on a lounge. Pain and fainting continued. At noon, her husband came in from his work, and medical aid was summoned. The family physician, residing several miles away, arrived at 2:00 P. M., and found her without pulse, countenance pallid, apparently dying from shock. A short examination determined what had probably happened. He was a man of energy and experience. He realized at once that he had to deal with a case of ruptured uterus at almost full term. At his request, a consultation and examination were carried out at the farm home. The diagnosis was unquestioned, the head of the foetus could be easily felt in the median line just

* Read at the annual meeting of the Seneca County Medical Society, at Willard, N. Y., October 12, 1931.

beneath the wall of the abdomen, and it appeared that the entire body of the child had escaped from the uterine cavity into the peritoneal sac.

An improvised stretcher was made from an ordinary household ironing board, upon which the patient was carried for a distance of about one quarter of a mile to a waiting automobile, and the patient was rapidly transferred, on the board supported on the backs of the seats, to the hospital. After a short abdominal preparation, by shaving and washing, she was placed upon the operating table, and 1,000 c.c. of normal saline solution slowly instilled into the right bicipital vein. The patient was conscious and rational. The heart sounds could be heard by stethoscope, but no pulse could be felt in either wrist. Hypodermoclysis was then resorted to. Saline solution being infused under the skin below each breast. This procedure was continued throughout the operation. In all, 2,400 c.c. of saline solution was used. Other assistants having arrived, it was decided to proceed at once with operation. Ether was administered, and a right median abdominal section made, incision being about ten inches long. Upon opening the abdomen, a vast quantity of mixed blood and amniotic fluid poured forth. The blood had clotted in the pelvis and in the renal fossæ. The fluid blood and amniotic fluid were sponged away, sterile soft towels being used as sponges. The dead child and placenta were free in the abdominal cavity, and were removed at once. The uterus was found to be split longitudinally from fundus to cervix, anteriorly. It was empty, well contracted, spread widely open, and in size and appearance it resembled very much a large, split muskmelon, about the size of the two closed fists. All the fluids having been removed, and the intestines packed off by large gauze pads, all bleeding was found to have ceased. It was decided to remove the uterus, which was done forthwith, using the technique of ordinary supravaginal hysterectomy. The left ovary and tube which were pathologic and, consequently, useless, were removed along with the uterus. A very long and diseased appendix was then removed. The abdomen was closed in layers without drainage. These operative procedures were easily and quickly performed as the abdomen lay widely open and complete relaxation was present. The condition of the patient upon removal from the table was

unchanged. No pulse could be felt in either wrist. One pint of saline solution, 5%, was injected into the rectum immediately after her return to her room.

Time of operation, 65 minutes.

Subsequent history.

November 10, 1928—T 102—P 140—R 24. Abdomen slightly tympanic. Voided naturally.

November 11, 1928—T 100.4—P 80—R 22. Patient's condition exhibited a marked reaction for the better. She expressed a desire to eat.

Further progress of the case was noted, as an uncomplicated, uneventful recovery.

Comment.

The striking features of this case were:

1st. The ability of the individual to withstand shock.

2nd. The evidence that the hemorrhage from the uterine rupture had ceased by natural uterine contraction before the opening of the abdomen.

3rd. Since the rupture had taken place through the scar tissue line of two preceding uterine incisions, it is strongly suggested that after one or more Cæsarean sections, that sterilization of the female is indicated. Authorities differ on this point.

Swift believes that while every case presents a separate problem, and that no woman should be sterilized on her first Cæsarean section unless there are definite indications of danger, other than the possibility of a second successive Cæsarean section.³

Holland in England has shown that the danger of rupture of the uterus in mothers who have been delivered by Cæsarean section is one to four labors.⁴

4th. The consensus of opinion in this class of cases would indicate that the maximum number of Cæsarean sections for any one mother should not be more than four, and that sterilization during any one of such major surgical procedures might be undertaken with perfect ethical propriety.

NOTE. From a considerable mass of literature pertaining to this subject, I have selected a few striking articles which are especially valuable for reference, which are arranged in the form of a bibliography below.

THE EFFECT OF NOISE ON THE NERVOUS SYSTEM. A PLEA FOR OFFICIAL ACTION BY THIS SOCIETY TOWARD ABATEMENT OF THIS DAMAGING NUISANCE*

By LASALLE ARCHAMBAULT, M.D., ALBANY, N. Y.

IT is already several years ago that an anti-noise campaign was launched in the leading capitals of Europe and more recently in this country, but it is only within the last two or three years that the movement has become actually militant. Those of us who read the *Journal of the A.M.A.* surely must have been impressed with the huge amount of information that has come to us from abroad, under the heading of "Foreign Letters," regarding the intensive study of the noise-problem and the measures taken to combat this growing evil. Since 1927 I have taken note of at least 20 abstracts devoted to this extremely important question. While men belonging to every profession have long ago realized the pernicious influence of noise in its various forms, it is on the shoulders of the medical profession that plainly rests the responsibility of taking the necessary means to fully acquaint local government officials with the sinister effects of noise and urgently to demand that through adequate ordinances or statutes, the text of which local newspapers would be requested repeatedly to publish, they inform the public that noise abatement is one of the outstanding accomplishments that the municipal government actually intends to realize. Such steps have already been taken abroad by the British Medical Association (Noise Commission of London), the French Academy of Medicine (Committee on Noise) and corresponding medical organizations in Berlin, Vienna and elsewhere. In this country, the Health Department of the City of New York published in 1930 a booklet entitled "City Noise," representing the results of an extensive investigation carried on by the "Noise Abatement Commission" composed of prominent citizens and above all of some of the most eminent physicians in New York City. The revelations contained in this booklet, based not on mere conjectures and guess-work but on the most unassailable scientific methods, are simply appalling. They fully confirm the observations and conclusions already published by foreign scientific bodies.

It is generally held that the progress in the civilization of a race or country is to be measured not only in terms of mechanical, industrial, educational and scientific advancement but also in terms of the personality traits and behavioral characteristics of its inhabitants. Granting that this adage is correct, it is a sad commentary on the civilization of our own nation that we are becoming noisier each year and that the conduct of a large contingent of our population rivals the

primitive habits and customs of the original lords of our land, the red men of North America. The reciprocal jealousies and enmities of the various Indian tribes and the resulting war dances, howling feasts, brutal revenges and weird ceremonials of various kinds were no more inhuman or incomprehensible than are many practices and performances tolerated in the present generation.

I cannot possibly undertake the consideration of all the varieties of noise which collectively constitute a steadily growing menace to public health, this already has been done and well done by others. It is my intention in this paper merely to present to you the more important data thus far available regarding the actual effect of noise on the economy in general and on the nervous system in particular, and, further, to discuss certain varieties of noise, for the existence of which there is no legitimate excuse and which a wide-awake city government surely can suppress, if not entirely, at least in very large part.

EFFECTS OF NOISE

1. The effect of noise on sleep. It is universally admitted that the average individual requires from 6 to 9 hours of sleep in order to remain fit physically and mentally. The pediatrician knows that in infancy and childhood a much greater amount of sleep is absolutely necessary. Every physician has learned how important are rest and sleep in the case of expectant mothers, invalids, patients critically ill in their own homes as well as in hospitals. Finally comes the case of night workers such as: nurses, printers, railway employees, night-watchmen and others who can obtain sleep only during the day and in whom insomnia assumes particular importance in that it not only saps their vitality but jeopardizes their ability to continue their occupation. Professor Portier of Paris, an authority in physiology, has stated that "noise diminishes the recuperative value of sleep even though sleep is not interrupted for the brain continues to receive auditory impressions even though it does not analyze them." I have had more than once the occasion of verifying the correctness of Professor Portier's statement. While examining patients at their homes I have seen babies jerk and twitch in their sleep at the bark of a police dog or the continued tooting of an automobile horn, thus witnessing the birth, so to speak, of subsequent instability or neurosis. As a neurologist of more than 25 years' experience, I have had abundant struggles with the problem of insomnia and its relief. To be sure noise is not the only cause of insomnia but it constitutes nevertheless one of

* Read before the Medical Society of the County of Albany, April 26, 1932.

the most important factors involved in the case of persons whose means or occupation oblige them to dwell in the more congested tenement districts. We cannot all afford to live in the more quiet residential sections of the city or under the peaceful skies of suburban villages. Much as I detest to resort to drugs for these patients I do not hesitate to prescribe some of the milder sedatives and hypnotics in order to facilitate or procure sleep, being morally convinced that the judicious use of such medication in properly selected cases is infinitely less detrimental and demoralizing than the persistent insomnia which exhausts both the physical energies and the moral stamina of the struggling victim. Moreover it is a well known fact, although this particular aspect of the problem receives insufficient emphasis, that many people can, under the present laws, obtain these various drugs and hypnotics of their own accord and regulate the dosage themselves. I have even known otherwise honorable citizens who were impelled to have recourse to narcotics in order, as they themselves state, to stay on the job.

2 The effect of noise on brain pressure. At Bellevue Hospital, in the Department of Neurology, Dr. Foster Kennedy and his associates have carried out experimental studies of the effect of noise on the brain in patients having undergone decompression (for tumors, old skull injuries, etc.) with removal of the bone flap. By employing a cleverly conceived device, a part of which lay on the integument overlying the brain and the other, consisting of a recording needle that impinged on a revolving drum covered with carbon blackened paper, they were able to get accurate graphic records of the increased brain pressure occasioned by noises of various qualities and intensities. These studies showed conclusively that the brain is exquisitely sensitive to noise and that its reaction to this potential traumatism can be measured as accurately as the blood pressure or the sugar content of the urine.

3 The effect of noise on the cardio-vascular system. Many research workers in this field have studied intently certain groups of workers such as stenographers, bookkeepers and office clerks and have described as the direct result of noise, heightened pulse rate, heightened blood pressure, irregularities in heart rhythm, all of which simply means that the individual is attempting to overcome the distraction or obstruction by putting forth additional energy in order efficiently to acquit himself of his task. These observations lend support to the belief that the effect of continued noise is premature degenerative changes in the heart and blood vessels.

4 Effect of noise on mental effort and concentration. Noise seriously interferes with the efficiency of the brain worker. It lessens attention, renders proper concentration upon any set

task impossible, requires undue expenditure of energy or extra effort and imposes excessive fatigue. While this affects more especially school children, college students, teachers and brain workers in general, it has been shown that noise likewise adversely affects workers in the humbler walks of life, those engaged in various trades. Hence the high incidence of occupational strain and the occurrence of so called nervous breakdowns, instability, neuroasthenic and psychasthenic complexes and so on. Robert Armstrong Jones speaking for the Noise Commission of London states "It further believes that neurosis may be attributed to noises just as in the case of shell-shock. Unless something is done to check this evil, we may find ourselves deprived of a capacity for sustained work, clear thinking and energetic action which is the mainstay of civilized life." Sir Maurice Craig, the psychiatrist of Oxford, England, declared that the popular view that people should be able to get used to noise as to so many other things in life was a dangerous error and authorities the world over have admitted that to the busy brain worker the sick and the wakeful, noise is a serious menace to which adaptation may be totally impossible. Closing the windows implies inadequate ventilation and even this does not suffice in the case of professional men grappling with intricate problems.

5 Effect on hearing. Competent otologists have furnished unchallengeable statistics on the damaging influence of noise on the special sense of hearing and consequently on the progressive weakening of the worker's efficiency. It is known that there are more than 25 noisy trades whose workers suffer from industrial deafness. German observers consider that tinnitus aurium of some type or other dizziness and headache are positive evidence of direct lesion of the internal ear caused by noise and, in Berlin, deafness arising from noise is a compensable industrial disease. A British author believes that as our own cities become noisier occupational deafness will increase among printers, bus drivers, road breakers, traffic policemen and still others.

6 Finally, Laird and his co-workers at Colgate University have shown that the normal development of infants and young children is seriously interfered with by constant loud noises.

After a just appraisal of the foregoing data, what more proof do we need of the extremely detrimental effect of noise on the general health of the individual and on the functional integrity of his brain and special senses in particular? It is perfectly obvious that the noise evil has assumed such proportion that we can no longer ignore the necessity of uniting all of our resources in order to check its further growth and, if possible to substantially reduce its present volume.

The medical profession, the public health departments and the State and Federal Governments

have long ago recognized the importance of vigorously combating the ravages caused by physical ailments; nationwide and even international crusades have been organized against tuberculosis, cancer, syphilis, malaria, yellow fever, diphtheria, etc., the State of New York has voted a considerable sum for the purchase, collection and proper distribution of human immune serum in its fight against poliomyelitis. There has been therefore no negligence in the attempt to save life and minimize physical deformity but does not the mind deserve at least as much attention as the body? What purpose does a physically perfect organism serve if it be not directed by an equally sound and efficient mind? It has been shown conclusively that by interfering with sleep, causing dangerous variations in arterial pressure, overtaxing nerve energies, noise materially diminishes intellectual output, undermines the stability and resistance of the entire nervous system, and predisposes to various types of neurosis and psychoneurosis. Surely it cripples the mind just as severely as external violence or infection disables a joint or a limb.

As previously stated it is my purpose to discuss more especially certain types of noise which are, in large measure, preventable. Some forms of noise disturb us less than others either because of their rhythmical quality or because we have grown up with that particular variety of noise and have become accustomed to it. There are some types of noise such as locomotive or tug and steamboat whistles that one cannot well eliminate, particularly in times of heavy fogs, although there can be no question that some of it is totally unnecessary. As to Albany, we wanted a Port of Albany, we now have it and shall have to put up with whatever annoyance it has in store for us. As to the most exasperating noise caused by pneumatic drills and riveting, the time presumably is not far off when the ingenuity of man will supply us with less disturbing mechanical devices.

The outstanding cause of unnecessary noise is furnished by automobile horns, breaks and cut outs. The average automobile driver is intoxicated with the power of speed within his grasp, he itches with the desire of supremacy and owns the road. In order to clear his path, he mercilessly blows the horn, totally devoid of consideration for the rights of pedestrians or even for the infirmities of his fellowmen. To my mind he is the most accomplished barbarian of the present day. While it is granted that speed is permissible on the highway, it should not be tolerated within city limits. If we except the congested thoroughfares of the shopping district where traffic is so jammed that speed is a material impossibility, I do not hesitate to affirm that cars are commonly driven in other sections of the city at the rate of 30 miles and even 40 miles an

hour. If a horse were driven at a speed averaging a mile in three or four minutes, his driver would be labeled a maniac or a fiend and he would land in jail in no time. This very speed is in large measure responsible for much of the unnecessary blowing of horns and other sound signals. Another cause of this evil is the farcical brevity of the supposedly safeguarding yellow or amber light. The fact is that wherever Traffic Light Signals exist (and surely they are sufficiently abundant in our city), barely a two-second interval elapses in the shift from red to green or vice versa. This simply means that the channel is open at the same time for both autos and pedestrians and of course the pedestrian has not the ghost of a chance. It is obvious that the whole situation could be remedied, first by reducing the speed limit to 15 miles an hour within the confines of the city, which represents the limit rigidly enforced in Berlin, Germany, and, secondly, by lengthening the duration of the amber or caution light to at least 30 seconds or more as is actually the case in the city of Boston. This surely would protect the legitimate rights of pedestrians in general, of the lame, blind or otherwise crippled in particular and materially cut down the amount of totally unwarranted klaxon tyranny. At night there is absolutely no excuse for blowing horns at every corner, when traffic is so light and reasonable slowing down could avert almost every chance of a mishap. Another ignominious performance on the part of many autoists is to pull up to the curb of a given home and blow the horn until the awaited party opens the window or steps out of the house. This practice occurs right along, not only during the day but at all hours of the night. Why cannot the driver or some other occupant get out of the car and ring the doorbell? No, he is too lazy to do so and the fact that he disturbs or awakens the neighbors or perhaps a sick or invalid person gives him no concern whatever. Finally, the very quality of the sound emitted by automobile horns could with a little good-will be so modified as to become infinitely less objectionable. It seems that one of the main ambitions of producers is to put on the market ever more piercing and startling types of horns. It should appear obvious to all that low toned, melodious horns are quite as efficacious and reliable as those sounding high pitched and strident notes and surely decidedly less irritating.

Loud playing of musical instruments or the operation of phonographs and loud speakers before open windows not only at all hours of the day but far into the night represents another nuisance that is steadily increasing especially since the advent of the portable type of radio which enthusiasts carry around with them and turn on aboard trains, steamboats and even in hotel rooms. This form of noise is particularly in-

dulged in during the warmer months which actually constitute in our climate the greater half of the year. During this period moreover the Daylight Saving Time measure has succeeded in slashing one hour from the already short night so that it has become practically impossible to find quiet anywhere or at any time. This is simply another instance of selfish and inconsiderate behavior on the part of unneighborly neighbors. I well realize that this particular brand of noise cannot well be stopped by municipal ordinances and that it is largely a matter of developing higher ethical standards among the masses. Legislation can no more enforce good manners and principles of decency than it can the disastrous prohibition law.

I come to another variety of noise that could be suppressed without the slightest difficulty, I believe, by adequate municipal statute. I refer to the totally unwarranted and wanton disturbance occasioned by the hoarse yelling of newsboys parading the streets at all hours of the day and night for the purpose of selling extra editions. Granting that such a rude awakening would be not only pardonable but indeed imperative did it serve the purpose of warning exposed citizens of some possible impending disaster such as a hurricane, an earthquake or a rapidly spreading fire of colossal proportions, it assumes an entirely different complexion when one realizes that peaceful citizens are routed out of their sleep night after night by thunderous shouts of "extra, extra," almost invariably designed merely to acquaint us with the details of a raid on a speak-easy or disorderly house, a murder or criminal assault of some kind or heroic exploits of the Jack Legs Diamond variety. Surely we can well afford to wait until morning to be feasted with such degenerate and gruesome news at the breakfast table. Even the distressing Lindbergh incident that has brought sorrow to the heart of the entire nation provides no legitimate excuse for further victimizing our people. That such an unwholesome and ruthless practice should exist in a civilized community would be totally inexplicable were it not for two reasons, both of them very bad reasons, namely the greed of the newspapers on the one hand, the morbid curiosity of a very small contingent of the population on the other. That supplementary editions be peddled around during the day is bad enough but certainly no such privileges should be granted the newspapers between the hours of 10 P. M. and 7 A. M. From this standpoint the present freedom and immunity of the public press is a disgrace. In a circular recently issued by the Albany County Mental Hygiene Association, of which Dr. Lloyd H. Ziegler is president, a special section is devoted to abatement of unnecessary noise and mention is made of the desirability of enlisting the support of newspapers encourag-

ing them to discuss the noise evil. Before calling on the newspapers for help in educating the public, it is perfectly evident that the first logical step in our campaign would be to educate the newspapers themselves as they are among the very worst offenders. In the city of Paris all street shouting and loud signals are forbidden after 10 o'clock at night. Why cannot Albany Albany pursue a similar policy?

The latest addition to the organized noise producing forces is the airplane. This is not the place to discuss the unquestioned and manifold merits of this modern vehicle of transportation but the roaring, deafening noise it leaves in its wake is a most objectionable component of its activities. Why should not the airplane restrict its operations along established lanes of travel and why is it permitted to fly and manoeuvre mercilessly day in and day out over cities, towns and villages?

Finally come the exasperating and perfectly preventable orchestral performances of dogs and cats. The traditional feud between the dog and the cat, old as the world itself, requires no additional emphasis, and it is well known that the cat is largely responsible for the dog's bad behavior. It is probably true that owing to the cat's arboreal and acrobatic agility we cannot absolutely control the range of its migrations nor entirely escape from its nocturnal serenades and wrathful dialogues although much of the discordant symphony could be hushed if the average housewife, possessed of sufficient charity of mind, took the trouble to call the cat indoors at a reasonable hour of the evening. As to the dog, probably the most intellectual of all animals and certainly a most faithful friend of man, he has in recent years become almost the idol of our good people who have gone neither more nor less than dog mad. I hold no brief against the dog but I have a case against the owners of dogs who allow their animals to race about the streets and bark during hours after every passing automobile, carriage or individual, and those who deliberately run away on automobile trips or attend theatres and parties, leaving the dog for hours in the backyard not only during the day but until midnight and sometimes later. The result is incessant whining, howling and barking which renders all intellectual pursuit extremely difficult or impossible, awakens sleeping children and adults, tortures invalid or sick neighbors and injects poison into the life of a whole city block. Particularly obnoxious in this respect are police dogs with their wolf-like, terrifying notes. It is practically impossible to obtain any redress in such instances. The dog owners are entirely secure, they have a license to which in reality they are not entitled; they are totally indifferent to the suffering that they inflict on their neighbors and even on their own animals. The city is no

place to keep police dogs or other large dogs, they are confined within narrow quarters instead of being kept in the country where they could roam and ramble in peace. There is, in our community, the Mohawk and Hudson River Humane Society for the prevention of cruelty to animals, an organization to which I have given my support for many years, but we have no society for the prevention of cruelty to human beings. It is actually impossible to secure any lasting relief from this particular source of noise. I will not burden you with the recital of my own experience but will simply state that I have waged a losing battle for the last eight years and inform you briefly how the problem stands. You may seek help at the hands of the City Health Department or at police headquarters, you will be received most courteously and promised that something will be done. The barking ceases in large part for a week or so and then a relapse occurs. You again apply to the police who will tell you that it is a public health problem, which is quite correct, and the health authorities will contend that the matter pertains to the police and thus you are amiably rocked between the two departments. You then seek the opinion of a competent attorney who informs you that the only sure way of obtaining results is to have the situation aired in police court. If you actually attempt to carry out this suggestion, you will soon find out that it is practically impossible to get even a few witnesses to help you. People are afraid to go to court, afraid of reprisal on the part of the accused neighbor or held back by some influence or other. They prefer to endure the nuisance, no matter how bitterly they complain of it, than to face the ordeal of telling the truth before the properly appointed magistrate. Thus it is that the citizen's license to own a dog, even though the animal is seriously annoying any number of people, takes precedence over the word of reputable citizens. I know a dog fancier in Albany, a well-known and respected citizen, who told me that any dog could be trained and broken of its barking habit within a week. If such be the case it would be well for the City to stipulate certain conditions before issuing licenses right, left and center to dog owners or prospective dog owners and to see to it that such conditions are fully complied with. It should be a simple matter not to grant a license unless the owner can prove that the dog already is trained or agrees properly to train it at once and further agrees so to manage and care for the animal that it will not be a source of annoyance and disturbance to others. In Berlin police regulations on this particular point are very stringent; dogs are prevented from running around the streets between 11 P. M. and 7 A. M. and further must at all times be so managed that they do not disturb persons in the vicinity by their barking. Failure to observe these rulings results in removal

of the animal from the owner's premises to the control of the municipality.

I am well aware that the designing of a window to exclude as far as possible the noises of the street has received considerable attention abroad. Mr. E. T. Fisk, managing director of the Amalgamated Wireless, Ltd., of Australasia, has designed a new type of window which he asserts has an efficiency of 75 per cent or over in deflecting street noises. A number of these windows have been fitted to offices in Sydney and Melbourne and the device has been scientifically tested in Great Britain. Its construction is described in the *Journal of the A.M.A.*, 1932, March, 19th, p. 1004. Light and air are not obstructed but rain and dust are excluded. Obviously it will be a long time before this invention, provided it accomplishes all that is claimed for it, will have reached the phase in its history when it is both easily available and within the reach of everyone's financial means. In the meantime something will have to be done to remedy a situation which is steadily becoming more and more intolerable.

It is believed that sufficient evidence has been adduced to convince the medical profession that the noise evil constitutes a serious menace to the physical and mental integrity and consequently to the working efficiency of the individual, that a very considerable proportion of the noise is totally unwarranted and therefore preventable, and that it is the duty of the medical man to assume the task of presenting the problem to the local government and urgently request that suitable measures be instituted in order efficiently to remedy the situation.

As it is the capital of New York State, the City of Albany should welcome the opportunity of taking the lead in a State-wide noise abatement campaign. It should gladly accept the rôle of standard bearer in a movement designed to promote the physical well being, mental stability, and the industrial and intellectual efficiency of its inhabitants, thus giving powerful assistance to the public health department and tremendously increasing the range and importance of the latter's accomplishment. By judiciously enacting certain simple laws or modifying those already in existence and pledging itself adequately to enforce such statutes, our city government could give an example of courage, sagacity and humaneness which not only would redound to its credit but go a long way toward focusing the attention of the entire nation on its accomplishment and automatically start a spreading wave of reform in the interest of mankind.

To this end, I would respectfully suggest to the President of the County Medical Society that he forthwith appoint a committee of 3 or 5 members for the purpose of conferring with his Honor, the Mayor of Albany, regarding this vital problem of

noise abatement and submitting to him the main facts embodied and discussed in this communication or else a copy of the same so that he may have the opportunity of studying the problem in its entirety.*

Discussion by Dr. Lloyd H. Ziegler:

Dr. Archambault has presented in his lucid and convincing paper both the scientific and humanitarian reasons for noise abatement. I agree with everything he has said, and in my discussion can do little to add to the weight of his arguments.

That unnecessary noise has been regarded as a nuisance and a menace to health, especially mental health, is not new. Anti-noise societies existing for years in many European countries have obtained results. Most European cities are much quieter than our own. It is not entirely due to the greater number of automobiles which we have. Their street cars are built with quiet in mind. One hears no raucous, noisy newsboys on the streets. There are no loud-speaking radios blaring into their open streets. They have restrictions in many cities about auto-horns. Helsingfors, Finland, has reduced auto-horn blowing to almost nil. Children are not allowed to make all the noise they wish at any time of day or night.

There are very few hospitals even in the United States that are not protected by a quiet zone. If it is deemed essential for sick patients, it must be desirable for those that are well.

Noise abatement is a public health problem of vast magnitude. As our country got richer and richer in its orgy of mass production, it got noisier and noisier. Freight that used to go over railways now goes down our residence districts, carried by noisy, lumbering, and, many times, unserviced trucks, often at night so as not to be interfered with by daily traffic. It used to be the pride of an automobile manufacturer to make cars more and more quiet. This has given way to another craze for superlatives, but in recent years power and speed have been the chief ends. Power and speed have been attained at low cost by high revolution engines which hum and vibrate. The Klaxon has been brought out to keep the already mounting death rate (90 per day, due to automobile accidents) from going even higher.

In a recent survey of 25 of the largest cities of the United States, relative to public health measures to control noise, the officials of all realized the import of the growing noise problem. None

had a legal program anything like adequate. A few have educational programs which are inadequate.

From a scientific standpoint, I wish to add only one bit of evidence to the many given by Dr. Archambault in favor of noise abatement. It is the work of Watson¹ on conditioned reflexes in infants.

I. Watson maintains that the elemental stimuli which will bring out fear responses are:

1. Sudden removal of support.
2. Sudden loud sounds.

II. For a subject he used a child 11 months old that had lived in a sheltered environment.

III. The child on repeated tests was not afraid of a black cat, a white cat, a pigeon, a rabbit, or any of these including a dog presented in a very dark room.

IV. A white rat was presented to the child at the time a bar of steel was struck a loud blow behind its head. This was repeated several times. Later the child showed typical fear reaction when the rat alone was presented.

V. In subsequent trials it was found that the child showed fear reactions to a rabbit, a dog, a fur coat, cotton wool, and a man's hairy head.

An engineer² has said that "within a generation noise will vie with disease unless the same mechanical ingenuity that has called the mechanical robot of the age into existence shall also be able to endow it with a soul of quiet."

To further bring out the extent to which noise has grown in our cities, the Noise Commission of the City of New York has learned that there are many places in New York where a Bengal tiger could roar without being heard at a distance of twenty feet.

The timely suggestions of Dr. Archambault outline for Albany an opportunity to pioneer in this aspect of the public health movement. Physicians everywhere should do what they can to defend the sick and well from unnecessary noises. Of engineers much technical skill will be required in noise prevention. Newspapers may do a great deal to educate the public about the significance of this unsanitary condition. It has been suggested that manufacturing devoted in one way or another to noise reduction and abatement may be the next great stimulus to prosperity. The time has come when it will undoubtedly pay to be less noisy.

BIBLIOGRAPHY

* The President of the Society appointed a committee on Noise Abatement consisting of Drs. LaSalle Archambault, Andrew MacFarlane, and Lloyd H. Ziegler. This committee was granted a preliminary hearing before the Mayor, May 5, 1932.

A STUDY OF PRIMIPAROUS PATIENTS IN ACTIVE LABOR WITH UNENGAGED HEADS

By LOCKE L. MACKENZIE, M.D., NEW YORK, N. Y.

Some of the clinical material used in this study was obtained from the Second (Cornell) Division of Obstetrics at Bellevue Hospital, from the Manhattan Maternity and Dispensary, from the obstetrical service at the New York Polyclinic Hospital, and from the John E. Berwind Maternity Clinic.

Read before the Section of Obstetrics and Gynecology at the New York Academy of Medicine.

PPRIMIPAROUS labor usually begins with the head engaged in the pelvis. If it is not so engaged, one is always faced with the problem of determining the reason and subsequent treatment for this lack of engagement.

Most text books state merely that disproportion or deflexion is the reason for this condition, and that the head normally descends into the pelvis before the onset of labor. Actually, this is not always true, and it was with a desire to clarify this point that the present study was begun about four years ago. Since that time it has been possible to collect this series of 50 patients both in clinic and in private practice. The exact incidence is unknown but it is very small, these patients having been seen personally during the observation of several thousand deliveries. This paper does not concern itself with the treatment of unengagement, but is rather confined to the ætiology and the results.

It is necessary to define as exactly as possible what is meant by an unengaged head, and by active labor. By the former is meant a head that is floating—that is, it is freely movable by abdominal palpation above the pelvic brim, and not merely fixed in the inlet and a little movable by bimanual palpation or by Pawlik's grip. The definition of active labor is more difficult, as it is always subject to personal interpretation. However, it is understood that the patient is having hard, rhythmic pains of no greater periodicity than five minutes. False labor was excluded by progressive cervical dilatation and thinning of the lower uterine segment.

Each patient was studied from 8 points of view to be taken up in detail in the next section. The information was tabulated, and, when amenable, averaged.

1. Age.

The average age was $23\frac{1}{2}$ years. The oldest was 35 years of age and the youngest 16. One (2%) was 35, while 7 (14%) were between 30 and 35 years old.

2. Gestation.

The term was calculated by the menstrual history. The lowest term of gestation in this series was 36 weeks (2 cases), and the highest was 44 weeks (1 case). The average was $40\frac{1}{3}$ weeks. The slight prolongation of gestation may be accounted for by the fact that the head was not in close contact with the cervix and therefore did not materially aid in effacing the lower segment.

3. Duration of Labor.

The average duration of labor was $22\frac{3}{4}$ hours. The longest labor was 47 hours, and the shortest 5. Nineteen patients (38%) were in labor 24 hours or more.

4. Condition of the Membranes.

In each case intact or ruptured membranes were noted. In 1 case this information was unknown. Thirty-five (70%) had intact membranes, and 14 (28%) had ruptured membranes.

5. Delivery.

The method of delivery was by Cæsarian section in 12 instances (24%), and from below in 38 (76%). Of the latter 30 (78%) were spontaneous, 2 (5%) by low forceps, 5 (12%) by mid-forceps, 1 by version and breech extraction, and 1 by craniotomy. As this series includes almost all the cases of badly contracted pelvis, the Cæsarian incidence is low.

6. Weight of the Baby.

The average weight of all the babies was almost exactly 7 pounds (3175.7 Gms.). The largest baby was 9 pounds 4 ounces (4195.7 Gms.), while the smallest weighed 3 pounds 6 ounces (1540 Gm.). Three babies were lost—one a macerated stillbirth delivered spontaneously; one a dead baby delivered by craniotomy; and the third a baby delivered by version and breech extraction. The third baby had been dead in utero for about 3 days, the cord being found 4 times around the neck causing a posterior face presentation.

7. The Pelvis.

Pelvic measurements varied greatly. The type of pelvis was estimated by both external and internal measurements. Seventeen patients had ample pelves. Of these 14 babies were delivered spontaneously, 1 by low forceps, 2 by mid-forceps, and 1 by Cæsarian section, there being 1 case of twins. Thirteen women had simple flat pelves. Of these 9 were delivered spontaneously, 1 by version and breech extraction, 1 by mid-forceps, and 2 by Cæsarian section. Three patients had a flat rachitic pelvis, and all were delivered by the abdominal route. Generally contracted pelvis was noted 11 times, and here 5 babies were delivered spontaneously, and 1 each by craniotomy, low forceps, and mid-forceps, and 3 by abdominal section. One woman had an absolute contraction (D. C. 7 cm.) and a generally contracted rachitic pelvis and was delivered by Cæsarian section. Finally, in 5 patients who had funnel pelves, delivery was spontaneous in 2, accomplished by mid-

forceps in 1, and by Caesarian section in 2. Some type of pelvic contraction was present in 60% of the cases.

8. Race and Nationality of the Patient.

As race and national characteristics might influence this study, these factors were investigated. It was found that 28 patients were American born—among them 8 negroes, while 22 were foreign born, these coming from 8 different countries. Of the 8 negroes the incidence of Caesarian section was 50%, but 7 of these women had contracted pelvis.

Discussion.

It should again be emphasized that this study was not undertaken in order to suggest any specific treatment for unengaged heads, as this obviously varies with the cause. The most frequent cause in this series seemed to be intact membranes with copious fore-waters. Often the head did not engage until the membranes were ruptured and then it immediately descended into the pelvis.

In a smaller number flattening of the inlet was a factor preventing engagement, and here it made no difference whether or not the membranes were intact. A few cases were encountered where an unusually large head did not engage in an otherwise normal inlet. X-rays might be valuable in such instances.

Posterior position has previously been thought to contribute toward the frequency of non-engagement of the head. However, it is felt that many heads engage in otherwise normal deliveries with the occiput posterior, and while this may be a factor in delaying descent in the mid-pelvis, it was not believed to play any part in the head entering the superior strait.

Deflexion and asynclitism may readily cause floating heads and in this series 2 face presentations were encountered. Neoplasms impinging on the pelvic inlet may also prevent engagement; none were found in this group. Placenta prævia—another factor—was noted 3 times. Weak abdominal musculature with pendulous abdomen may be one of the few reasons for this finding which is at times amenable to antepartum correction by the proper use of support and exercise.

Whether or not the cervix per se plays a fre-

quent role in the causation of floating heads may well be considered. Except in those cases where there is scar tissue due to previous operation or disease or where there is a malposition or presentation it was not believed that the cervix prevented the head from engaging.

Among other causes short cord should be mentioned. This may be an actual shortening or an apparent one as was the case in 1 patient in this series where the cord was wound about the neck 4 times, converting the presentation into a face.

The unengaged head in a primipara, even though she be in active labor, does not necessarily call for operative intervention. The majority of such patients deliver, or can be delivered, from below. The rationale of therapy depends in each case upon the causative agent and this must be found by studying a number of widely divergent factors.

If it is possible to indicate the type of patient in which this syndrome is likely to be found, this study seems to show the following: She is usually in the early twenties, only a few elderly primiparae having been noted; the term of gestation is a little prolonged; generally the membranes are intact; labor is prolonged beyond the average time; measurements indicate that the pelvis tends to be of the simple flat type, although there were a notable number having no contraction whatsoever; the weight of the baby is generally less than average.

Summary.

A group of 50 primiparae in active labor with floating heads has been reported, and various facts as to each patient, her labor, the delivery, and the baby are detailed.

When this condition presents itself it is necessary to estimate carefully the type of pelvis, the condition of the membranes, the presence or absence of some accidental factor preventing engagement, and to be sure that there is no malpresentation.

Conclusion.

Primiparae in active labor with unengaged heads, even though no reason may be found for lack of engagement, can often be delivered from below.

ANCIENT HEBREW MEDICINE

By BENJAMIN COHEN, M.D., AND WILLARD C. MONTGOMERY, M.D., SALEM, MASS.

THE Talmud of the Hebrews consists of extensive literature faithfully describing the knowledge, laws and customs of the Hebrews from Ezra to the sixth century of the present era. Basically, this work has two major divisions: The Mishna (text) and Gamara (commentary). The

commentary best known today had its origin in the Babylonian rabbinical academies at Sora, Nehardea and Pumbedetha. The collection and subsequent publication of this commentary is attributed to R. Ashi, Rabina and Jose in the sixth century.

The commentary consists of lengthy interper-

tations and rabbinical arguments concerning statements in the Mishna which seem to require clarification. Many of these discussions digress far from the topic under consideration and entail reference to medicine, law, botany and astronomy.

In the Middle Ages, several efforts were made to systematize and abbreviate the Talmud for purpose of popular reference. The most successful attempt resulted in the appearance in 1567 of the Shulchan Aruch (Code of Hebrew Law). The tone of the code on a whole is conservative, in striking contrast to the occasionally fantastic opinions registered in the Babylonian commentary.

The Bible itself was the primary authority, and a relevant reference to the Old Testament was the most conclusive argument in Talmudical discussion.

Privileges of the Physician

The Kitzur Shulchan Aruch (Code of Jewish Law, Chapt. CXII) leaves no doubt as to the importance of the Physician: "The law has granted the doctor the privilege of healing. . . . Therefore the sick person should not rely upon a miracle, but is in duty bound to act according to worldly custom and call in a doctor to heal him. . . . He who avoids calling the doctor is guilty of two faults: In the first instance of transgressing the rule forbidding one who is in danger to rely upon miracles; and the other is that he manifests presumption and pride in depending upon his righteousness to cause him to be healed in a miraculous manner. It is the religious duty of the doctor to heal. . . . If he avoids doing so, he is guilty of bloodshed."

Further, writes Joshua, son of Siroch: "Honor the physician with the honor due him, for the uses ye may have of him. . . . In the sight of great men he shall be in admiration. . . . The Lord hath created medicines out of the earth and the wise will not abhor them. Give place for the physician. . . . let him not go from thee, for thou hast need of him."

Reference to therapeutic abortion is found in CLXXXIV of the Code: "When a woman is in parturition with great travail, the doctor is permitted (in a critical case) prior to birth, to sever the embryo with instruments or with medicine, for if it had not come forth, it is not accounted as a living soul; and it is permissible to save the mother by sacrifice of the embryo. . . . but if it protrudes its head, then it must not be touched, for one living soul must not be sacrificed for another."

False modesty is deprecated (Code CXCI): "A physician is permitted to let blood and to feel the pulse or any other place of a woman, even if she be married, even the pudenda, as is customary with physicians, since he does not do so in a sensual and immoral spirit, but is merely following his profession."

Miscellany

Health and disease were of heavenly origin ("I kill and I make alive; I have wounded and I heal"—Deut. 32, 39). Hebrew laws were to be followed implicitly, but could be set aside when illness demanded it (with the exception of the laws dealing with idolatry, adultery and murder). The Biblical text sanctioning deviation from the law in the interest of the sick was the following: "Live through them (the laws), but do not die through them (Lev. 18, 15).

Tanneries and cemeteries could not be built within 50 cubits of a city. Military sanitation is discussed in Deuteronomy (23, 9-14). The presence of diphtheria was announced by the warning blast of the shofar (ram's horn).

Leprosy is discussed in Leviticus 13, 23: "When a man shall have in the skin of his flesh a rising or a scab or a bright spot . . . and if the bright spot be white and not deeper than the skin . . . and the skin be not turned white . . . then the priest shall shut up him that hath the plague for fourteen days, and behold if the plague be diminished, . . . and if not spread in the skin . . . it is a scab, and he shall wash his clothes and be clean. But if the scab spread abroad in the skin, . . . it is leprosy."

And in 13, 45-6 (ibid) we read: "The leper in whom the plague is, his clothes shall be rent, and the hair of his head shall go loose . . . and he shall cry: 'Unclean, unclean!' . . . and he shall dwell alone without the camp."

The birth stool is mentioned in Exodus, 1, 16, and bandaging in Ezekiah 30, 22. The medicinal value of figs is described in Isaiah 38 (1-8): "For Isaiah had said: Let them take a lump of figs and lay it for a plaster upon the boil and he shall recover."

Sweating, sneezing and movement of the bowels were regarded as favorable omens in the progress of a disease. Baas tells of onions in the treatment of worms, milk sucked directly from the teat of a goat for the relief of dyspnea, wine and pepper for stomach disease, massage with broth for the relief of sciatica.

Perspiration was considered toxic in character, and hands which had come in contact with sweating parts were to be scrubbed thoroughly. Leeching and cupping were employed generally. Venesection was exceedingly popular and Mar Samuel Yarhevai is said to have advocated routine venesection once in 30 days (Shab. 129b.).

Sleeping potions were advocated for anesthesia. Crutches are mentioned (Shab. 65a.); edges of old wounds were freshened to facilitate union; artificial teeth were fashioned of hard wood, gold or silver, Shab. 65a.).

Some of the common drugs were acacia, wormwood, myrrh, saffron, cumen, aloes, citron, henbane, juniper, lettuce, flax, mandrake, olives, cas-

tor oil plant, pomegranate, antimony, charcoal, lead, bronze, copper and lapis lazuli.

From the Shulchan Aruch (Chapt. XXXII) we quote a few rules of health: "He who is desirous of preserving his health must recognize the emotions and take care of them and these are: Joy, worry, anger, fright. . . . One should be in good spirits and joyous to a moderate extent, because this state causes increase of natural warmth, improved digestion and excretion, strengthening of vision and the power of reason."

"Moderate sleep is good for physical health, from the viewpoint of rest and improved digestion. Too much sleep is injurious, because the head becomes filled with gases . . . and causes a great deal of injury to the body. . . . When one sleeps, his head should be higher, because it helps the food come down from the stomach and the gases that come up in the head will be diminished."

"One should take a bath regularly every week . . . one should wash his entire body with hot water, then with tepid water and finally with cold water."

Food and Digestion

The physiology of digestion is covered in most interesting fashion in the Shulchan Aruch (Chap. XXXII). Some of the most fascinating passages follow: "The Creator granted man and all living beings the natural warmth which is life itself, because if the natural fire of the body should be quenched, then life ceases. This warmth is maintained by the food which man eats; just as in the case of a burning fire, if wood is not added continually, it will be quenched entirely. . . ."

"The food is ground between the teeth and becomes mixed with the juice of the saliva and is reduced to slags. From that point it goes down into the stomach where it is likewise ground and mixed with the other juices, the juice of the stomach and the juice of the gall. . . . It is boiled by means of the heat and the juices and thus becomes digested."

"Out of the pure parts (of the food) the limbs are nourished and life of man is sustained, and the impure (elements), which are unnecessary are driven to the outside. . . ."

"Easy digestion is possible when the food is not too excessive in amount, and not too indigestible in quality. For when too much food is eaten and the stomach is full, digestion is difficult for the reason the stomach cannot spread out and shrink properly and naturally, and ground the food as it should be. It is very much like fire, if too much wood be placed on it, it will not burn well. . . . Therefore the man who is desirous of preserving his physical health must take care to adopt the golden mean in eating depending on the nature of his body. . . ."

"On hot days the digestive system is weaker on

account of the heat, therefore it is proper that the portion of food on hot days should be less than on cold days . . . and the limit has been established that in the summer one should eat only two-thirds of the amount he eats in the winter. . . ."

"Before a meal one should have some exercise by walking or at work until his body becomes warm, concerning which is written, 'With the sweat of thy brow shalt thou eat bread' (Gen. 3. 14), and one should loosen his belt before eating and while eating should be seated or recline on the left side, and after the meal he should not move about too much. He should not promenade or tire himself out after the meal, neither should he take a nap immediately after the meal, before the expiration of two hours, so that the gases should not enter his brain and cause him injury."

"Men different in temperament, some are hot, some cold, some medium. Food differs also, and he whose temperament is medium should also partake of food which is medium. But one whose temperament is not medium should eat food which is a trifle reverse to his temperament. For example, he whose temperament is hot should avoid hot foods, such as spices and balsam plants and eat only food which is cool and somewhat fermented. . . . Food should be prepared in accordance with season and locality; in summer one should eat cooling foods, and also a little of fermented foods, but in winter one should eat heating foods. Similarly, in a cold climate one should eat heating foods and in a warm climate, cooling foods. . . ."

"In general, a healthy and strong person should eat twice a day, and the feeble and the aged should eat a little at a time and several times a day, because excessive eating at one time weakens the stomach. He who is desirous of preserving his physical condition should not eat before the stomach is absolutely empty of previous foods. The ordinary time for the digestion of food for people who are healthy and eat moderate foods and have moderate exercise is six hours. It is best to omit one meal during the week in order that the stomach may rest and its digestive powers strengthened. . . . One should first eat light foods which are easily digested; for instance, fowl meat should be eaten before beef. . . . Since digestion begins by grinding the food with the teeth and by intermixing it with the juice of the saliva, one should not swallow food without mastication, because digestion is difficult when left to the stomach alone. . . ."

"Regarding liquids, water is the natural drink and is healthful. . . . It preserves the moisture of the body and hastens the expulsion of waste matter. . . . Cool water should be preferred, because it aids digestion more than water which is not cold. . . . One should be careful not to drink cold water when tired and weary, because the fat of the heart

is hot and likely to become dissolved. . . . One should not drink water before a meal because the stomach becomes cooled off and will not digest the food properly. . . ."

"A man should endeavor to keep his bowels lax. . . . serious disease is more likely to ensue when an individual is constipated."

Commentary Medicine

Passages of medical interest are only occasional in incidence in the *Gamara* (Talmudical Commentary) and occur where their mention seemed necessary to elucidate or expand the *Mishna* (Text).

The following abstracts are quoted from the *En Jacob* (Agada of the Babylonian Talmud):

R. Juda quotes Rab: "The Holy One . . . created not one single thing in vain. He created the snail as a remedy for the scab of a camel; the fly for the sting of the wasp; the gnat for the bite of a serpent; the serpent itself for curing sores of the head. The remedy is prepared by boiling together a black and a white member of each species for application to the affected part."

Raba ben Samuel quotes R. Chiya: "Avoid harm by eating salt after each meal and drink water after every drink."

Baratha continues: "If a man drank every drink but water and ate every food but salt, he would be afflicted with a foul mouth odor during the day and croup during the night."

R. Mari quotes R. Jocha: "He is who is accustomed to eat lentils once in 30 days will be free from sickness; but daily use is undesirable because it is productive of a foul mouth odor. . . . Further, mustard taken once in 30 days prevents illness, but daily use is likely to affect the heart."

R. Chiya ben Ashi quotes Rab: "The man who accustoms himself to small fish will be free from a stomach sickness; moreover, his entire body will be strengthened."

R. Janai quotes Rab: "The egg exceeds in food value anything its size." Rabbin adds that a soft boiled egg is better than six ounces of fine flour. R. Dimi states that a soft fried egg is better than six ounces of flour and a hard fried one is better than four ounces of flour.

The Rabbis taught the following: "A milt is good for the teeth but not for the stomach; vetch is bad for the teeth but good for the stomach. All raw vegetables make the face green and all unripe things affect men. Every living thing eaten alive strengthens life; cabbage is a nourishing food. Beetroot is good for use in medicine, but woe unto the house where the turnip enters!"

"If one eats and does not walk four cubits, his food rots away, and causes a foul odor from the mouth. He who must ease himself and eats before doing so is like a stone which was heated upon its ashes; this is likely to produce a foul odor from the body. Washing without oiling one-

self is like pouring water upon a barrel. Washing in warm water and not drinking anything hot is like heating a stove from without and not from within. Washing in warm water and not having gushed with cold water is like an iron which was put into the fire but not plunged into water afterwards (to harden it)."

Medical Superstitions

No Hebrew literary work reveals popular ancient superstitions as well as the *Haggadah*. The question naturally lends itself—What is the scope and status of the *Haggadah*? Darmesteter answers it as follows: "In the immense field of the *Haggadah* (embracing history, legend and varied information of scientific character) the Oriental mind unfolds in all its wealth and fullness the beliefs, ideas and sentiments that animated the (ancient) Jewish, indeed the Asiatic world. . . . In this treasury lie heaped up the noblest . . . as well as the most fantastic thoughts that ever have crossed human brain. . . ." The *Haggadah* lacked legal and religious significance and many of its teachings were denounced.

The prolific imaginative Oriental mind found it quite easy to attribute the ills and misfortunes of mankind to the mischievous and malevolent designs of invisible spirits.

The *Haggadah* relates bizarre accounts of demons who have wings and fly from one end of the world to the other, eating, propagating and perishing, even as men do (Hag. 166).

Among the demons responsible for disease were the following: *Shabriri* (demon of blindness; *ruah Zeradah* (spirit of catalepsy); *ruah Palgah* (head-ache); *ben Nefilin* (epilepsy); *ruah Kardeyakos* (melancholia); *ruah Eshata* (fever).

An interesting description is given of the death-inflicting *Keleb Meriri*: He has the head of a calf with one revolving horn in the middle and an eye on his breast and his whole body is covered with scales and hair. Whoever sees him during the period of his reign (from mid-summer noon the 17th of Tammuz to the 9th of Ab) falls down and expires.

Shabriri, the demon of blindness, hides himself in water at night, hence the following warning: Do not drink water at night. The demon *Shabriri* is to be feared; he blinds those who drink. If, however, you are thirsty and must drink, awaken your companion and say, "Let us drink together." The demon will then remain quiet. But if you are alone and must drink make considerable noise with your pillow and repeat a magic formula (supplying your own name): Thou so-and-so, son of so-and-so thy mother has told thee: "Beware of *Shabriri*, *briri*, *riri*, *iri*, *ri*, *i*." The similarity of the latter part of the incantation to the *Abracadabra* of the Romans is noteworthy.

The Bible tells us of another method of driving

forth a demon (Samuel 16, 14-23): "But the spirit of the Lord departed from Saul and an evil spirit . . . troubled him . . . and it came to pass . . . that David took a harp and played with his hand so Saul was refreshed and well and the evil spirit departed from him."

Superstition probably prompted R. Huna to require the following in his treatment of malaria. Seven thorns from seven pine trees, seven splinters from seven beams, seven pegs from seven bridges, seven cinders from seven ovens, seven grains of dust from seven door pivots, seven kinds of pitch from seven ships, seven caraway seeds and seven hairs from seven old dogs.

R. Jochanan relates the following: "Against a burning fever take a knife made entirely of iron and tie a white hair to it and on the first day cut a notch into a thorn while saying the following verse from Exodus: 'The Angel of the Lord appeared unto Moses. . . .' The next day incise the thorn again and say: 'The Lord saw that Moses turned

aside to see.' The third day return to say: 'God said to Moses: "Draw not night hither." That done, bend to the ground and say 'Bush! It is . . . because thou art the humblest of the trees that the Holy One . . . has made His glory descend before thee. So may the fever which is in me flee before thee. . . .'"

Abajia offers an unique remedy in his statement that three madder-colored threads worn about one's neck are sufficient to halt the progress of disease, five possess distinct curative effect and seven safeguard the wearer from spells. "Yes," responds contemporary R. Aha bar Jacob, drily, "this is true, provided that the wearer of the threads sees neither sun, nor moon, nor rain, and hears not the sound of iron, nor that of the forge, nor the crowing of the cock."

The latter statement, as well as many others readily available, clearly indicates that in ancient times, as well as now, superstitions failed to gain general acceptance.

ADVANTAGES OF USING 16 MM. CINE-KODAK SUPER-SENSITIVE PANCHROMATIC FILM IN MAKING SURGICAL MOTION PICTURES

By R. PLATO SCHWARTZ, M.D., AND H. B. TUTTLE, ROCHESTER, N. Y.

From the Orthopedic Department of the Rochester University School of Medicine and Surgery and the Research Department of the Eastman Kodak Company.

Read before the Society of Motion Picture Engineers, Tuesday, October 6, 1931.

THE application of motion pictures to the general field of education is already receiving thoughtful consideration. The introduction of motion pictures as a method revealing operative procedures for the training of doctors is not expected ever to become of commercial importance. It is believed that this is an instance where values greater than economic assets must be considered. Human life, personal comfort, and familial advantages are all dependent on the results of any major surgical operation. No one of us is immune from these hazards.

Not all branches of surgery lend themselves readily to the use of motion pictures in the teaching of surgical technique. It follows, therefore, that care should be taken in the selection of the field chosen for our initial efforts, lest moving pictures be censured when

in reality the fault lay in the mind selecting the subject.

Individual patients present wide variation in the same condition which requires surgical treatment. Each surgeon may agree in principles governing operative procedures but differ in methods of execution. The method by which moving pictures are to be made available for the teaching of surgery cannot, therefore, be the same as that which is represented by Hollywood in the field of entertainment. Honest effort in this direction has already failed at the cost of several hundred thousands of dollars, chiefly because these two facts were not considered of great importance in relation to the outcome of the undertaking.

Because of these prevailing conditions our course is, for the present, well defined. It should be directed toward the solution of the

problems confronting the individual surgeon interested in the application of moving pictures to the problems of surgery.

FIGURE 1.

Bausch & Lomb Operating Room Lamp.

In this branch of motion picture photography, expense and essential technical skill at one time combined to retard progress. The advent of 16 mm. film and the reversal process relieved the first of these. The simplification of 16 mm. cameras, lenses, and the development of compact and efficient lighting equipment lessened the necessity for special training.

With these advantages embraced, other objections were made most evident. Chiefly among these was the reproduction of the operative field, which was always reddish in color. Panchromatic film offered an improvement, being slightly more sensitive to blue and green than to red, as compared to old regular film which was less sensitive throughout this range. While the red areas were rendered more accurately than before, there was still considerable difference between the operative field and the photographic reproduction on the screen.

The second important difficulty in making such pictures was the size and inconvenience

of using artificial lighting equipment. Lighting units consisting of three 500 watt bulbs were not readily accepted by the average surgeon, and the necessity of having an $f:1.9$ lens camera limited somewhat the field of surgical moving pictures. For those few who had lighting units available, the heat, together with the danger involved in meeting the demands of asepsis, prevented the close proximity of these lamps, camera and operator to the operative field to make clear, well-defined motion pictures.

Recently a new emulsion for amateur use, called Ciné Kodak supersensitive panchromatic film, has been placed on the market. While this

FIGURE 2.

Bausch & Lomb Floor Lamp.

film is twice as fast to daylight as panchromatic film, its chief advantage lies in its great speed when exposed to artificial light, to which it is three to four times faster than is the regular panchromatic film. Super-Sensitive film

is especially sensitized in the red portion of the spectrum so that most of its speed lies in the area in which artificial light is richest.

While this emulsion was designed for high speed work in motion picture studios where artificial lights are used almost exclusively, it was later adapted to the 16 mm. reversal process to enable amateurs to make pictures with low intensity lamps. It so happens that its characteristics are ideal for the making of surgical motion pictures.

Probably the most important advantage of this film from an economic point of view is the fact that it is no longer necessary to use any additional artificial light. The lights which are installed over most operating tables are sufficient for the making of good motion pictures. With the light found in most hospitals, it is possible with Super-Sensitive film to expose at diaphragms $f:3.5$ or $f:4.0$.

It is also possible with fast film and regular operating room lighting to use telephoto lenses. It can readily be seen that this is a very important factor, as heretofore with a one inch lens it has been necessary for the operator to hold the camera from three to four feet from the operative field in order to get an image the same size as could be obtained an image size which would show sufficient detail to be recognizable on the projection screen. With a three inch lens six feet from the operative field, it is now possible to get an image the same size as could be obtained with the one inch lens at two feet from the subject.

When using the 3 or $4\frac{1}{2}$ inch telephoto lens, it has been found advisable to use a tripod. It is almost impossible to hold a camera absolutely steady. While the small amount of body movement which does exist is not objectionable when a one inch lens is used, and the resulting field is fairly large, the long focus lenses magnify this movement many times so that the smaller field is unsteady.

	Camera Distances in Feet	Approximate Field Size in Inches	
1" LENS	2	7	$\times 9\frac{1}{2}$
	3	$10\frac{1}{2}$	$\times 14$
	4	$14\frac{1}{2}$	$\times 19$
	5	18	$\times 24$
	6	$21\frac{1}{2}$	$\times 28\frac{1}{2}$
3" LENS	6	7	$\times 9\frac{1}{2}$
	9	$10\frac{1}{2}$	$\times 14$
	12	$14\frac{1}{2}$	$\times 19$
	15	18	$\times 24$
$4\frac{1}{2}$ " LENS	9	7	$\times 9\frac{1}{2}$
	12	9	$\times 12$
	15	12	$\times 16$
	18	$14\frac{1}{2}$	$\times 19$

The data given above for the use of super-sensitive film is for operating rooms which are illuminated only with artificial light; in other words, pictures made with no daylight present.

A large percentage of all surgical operations are performed in daylight. Because of the diffusion of daylight in most operating rooms, the surgeon requires additional illumination of incisions and cavities by a spot light such as the Bausch & Lomb or Scialytic, 100 watt, 110 volt, floor lamp. This combined use of daylight and tungsten illumination provides advantages for both surgeon and the photographic recording of surgical procedures. A

FIGURE 3.
Scialytic Operating Room Lamp.

diaphragm opening of $f:4.0$ to $f:5.6$ is correct when these two sources of illumination are combined.

Variation in season, weather, and time of day so alters the intensity of daylight that it is impossible to give any precise data on the proper exposure. This variation of daylight in the operating room is a disadvantage to the surgeon. It has become more generally recognized with the development of efficient sources of illumination. For some years past many operations have been regularly performed to advantage in special rooms where no daylight was present. It has been suggested by Dr. J. J. Morton, Professor of Surgery, Rochester University School of Medicine, that in the future design of operating rooms, all daylight should be excluded. It is apparent that such

conditions would be helpful to the surgeon and further the application of moving pictures to the problems of surgery.

On regular panchromatic film, it was some-

FIGURE 4.
Macbeth Operating Room Lamp.

times advisable to use a K-3 or G filter to render the red area more faithfully. The use of such filters, however, made it necessary to allow two or three stops difference in exposure, thus sacrificing some depth of focus and general definition. Supersensitive panchromatic film is highly self-corrected, making it unnecessary to use filters in operative work.

The first experiments with supersensitive film were carried out at the Strong Memorial Hospital in Rochester, New York. Tests were made with three very different types of operating room lights having 110 volt circuits. All experiments were conducted at night so no daylight or room illumination would cause variations in results.

In order to have a cross-section of results obtainable with other types of 110 volt lamps, similar experiments were made at three other Rochester hospitals.

The summary of these tests showed that in operating rooms having from 400 to 600 watts available, at approximately 40 inches from the operative field, satisfactory exposures could be made at diaphragms $f:5.6$ to $f:8.0$; where 200 to 400 watts were available, diaphragms $f:2.8$ to $f:4.0$; and where only single units of 100 watts were available, diaphragms $f:1.9$ to $f:2.8$.

Strong Memorial Hospital, Bausch & Lomb mirror spot dome lamp, 500 watt, 110 volt lamp, 40 inches from operative field, at diaphragms: $f:1.9$ to $f:5.6$, and telephoto $f:4.5$.

$f:2.8$ — satisfactory exposure

$f:4.0$ — satisfactory exposure

3" telephoto $f:4.5$ — satisfactory

Scialytic, 1—100 watt, 110 volt, mirror reflector, 40 inches from operative field, at diaphragm: $f:1.9$ to $f:5.6$, and telephoto $f:4.5$.

$f:2.8$ — satisfactory exposure

$f:4.0$ — satisfactory exposure

3" telephoto $f:4.5$ — under exposed

A 100 watt, 110 volt auxiliary operating room spot light should be used with a 100 watt, 110 volt Scialytic.

ELECTRODIAGNOSIS, GALVANIC AND LOW FREQUENCY CURRENTS IN TRAUMATIC CONDITIONS

By RICHARD KOVACS, M.D., NEW YORK, N. Y.

Read as part of a course on Physical Therapy in Traumatic Conditions, arranged by the Committee on Public Health and Medical Education of the Medical Society of the State of New York, for the New York and Bronx County Medical Societies.

THE knowledge of the principle of action and of correct technique of employment of the currents of low tension and low frequency augments the physician's armamentarium with invaluable aids in the diagnosis and treatment of traumatic conditions, especially those of muscles and nerves.

THE GALVANIC CURRENT

The time honored galvanic or direct current, when employed in uninterrupted flow through electrodes of equal size and within the limits of comfortable toleration ("medical galvanism") causes marked hyperæmia at the site of application and mild heat, better nutrition, and an acceleration of metabolism in the area between the electrodes. These effects parallel somewhat those of the more popular method of diathermy or through and through heating by the high frequency current. There is a distinct place for medical galvanism in promoting the process of reparation and in the relief of pain in both acute and chronic traumatic conditions of soft tissues, such as contusions, sprains, synovitis. In order to be effective, treatments of one-half hour to one hour duration must be employed at a current strength of pleasant toleration, which usually amounts to about one milliamperere per square inch of active electrode surface.

Ionic medication consists of the driving of ions into the superficial tissues by the polarity effects of the galvanic current. The positive pole when applied as the active one repels metals and hardens tissue; the negative pole repels and softens tissue. These effects may be used to advantage for loosening adherent scars and in sterilizing and stimulating sluggish wounds and chronic ulcers. Chlorine ionization serves to loosen scars; a pad electrode soaked in saline solution and connected to the negative pole of the galvanic generator is applied over the scar; a large dispersive electrode connected to the positive pole is placed over a remote part of the body. A current of 2 to 20 milliamperes, its strength regulated according to the size of the electrode and the comfortable toleration of the patient, is made to flow for one-half to one hour. Dense superficial scars, if not too extensive, are being made pliable and thus readily amenable to subsequent mechanical stretching by massage or other means. Lighter scars and the discomfort caused by them can often be entirely relieved.

Copper ionization of sluggish wounds consists of packing the ulcerated surface or sinus with

small pledgets of cotton soaked in one per cent copper sulphate solution. An electrode of appropriate size is placed on top of this layer and connected to the positive pole while a large dispersive electrode is placed over a remote part of the body and connected to the negative pole. The repelling effect of the positive pole drives the copper ions into all interstices of the wound; ten minutes to half an hour treatments, always within comfortable tolerance, applied in frequent succession, will advance the healing in properly selected ulcers and wounds with surprising rapidity. This treatment is often the last resort in stubborn varicose ulcers.

Interrupted or surging currents of low tension and low frequency, such as the interrupted galvanic current, the faradic current, the slow sinusoidal and modulated alternating current, serve as stimulants of motor nerves and muscles. The classical method of electrodiagnosis and the treatment of various degrees of muscular weakness and paralysis is based on the chemico-physical effects of these currents. A bewildering variety of current modifications offered by eager manufacturers of apparatus, and a lack of generally accepted nomenclature and of unbiased research work have created at present some confusion in this potent field of electro medicine. There is, however, enough definite knowledge available to enable the efficient use of these currents.

ELECTRODIAGNOSIS

Electrodiagnosis signifies the application of a suitable electrical stimulus to motor nerves and muscles in order to bring about a contraction. This procedure serves to amplify or to corroborate clinical findings, notably for the differential diagnosis between organic (central or peripheral) and functional or hysterical cases of paralysis. It is an indispensable help in prognosis, and forms the basis for selecting the appropriate form of electrotherapy in peripheral nerve lesions.

The simple test by the faradic and the interrupted galvanic current is quite satisfactory for general purposes. The more accurate testing by condenser discharges requires more complicated apparatus and belongs to the laboratory or high type clinic. The fact that two forms of current are used for ordinary testing is somewhat bewildering to the beginner. The faradic current furnishes a series of rapidly recurring stimuli, each rising to a maximum in about 1/1000 of a second and recurring about 100 times in a second. The rapid recurrence of these stimuli keeps a

normal muscle in tetanic contraction during the entire time of flow, thus making observation of the response very easy. The galvanic current, while flowing steadily, furnishes no stimulus for muscular contraction; only when its flow is suddenly started (made) at sufficient strength, or is interrupted (broken) while flowing at sufficient strength, does a muscular response occur. The contractions are single contractions. It has been estimated that the impulse of the make and break of the galvanic current lasts about $\frac{1}{2}$ second. We have thus, for ordinary testing, a stimulus of very brief duration (the faradic current) and one of relatively long duration (the "make" of the galvanic current). Normal muscle and nerve respond to both of these equally well, but once the nerve supply is damaged the muscle will not respond to the brief faradic stimulus, but still responds to the longer impulse of the galvanic current.

The classical reaction of degeneration (abbreviated RD) consists of the following signs: The nerve does not respond to either faradic or galvanic stimulation; the muscle does not respond to faradism, but shows sluggish response to the interrupted galvanic current. It takes about ten days after an injury or disease for the RD to develop; the muscle ceases to respond to faradism between the fourth and seventh day, and sluggish galvanic response becomes evident about the tenth day. Partial RD signifies a feeble response to faradism and sluggish response to galvanism.

The importance of the RD in the prognosis lies in the fact that, when present ten days after an injury or disease, it indicates changes in nerve and muscle substance which will take considerable time—several months at least—to recover. The finding of an RD by no means indicates irreparable damage. If, ten days after an injury, accompanied by paralysis, there is no RD present, the diagnosis is "contusion" of the nerve, with only temporary disturbance of nerve conduction, and a prognosis of an early recovery can be made. The same significance prevails in cases of facial paralysis with no RD present, as compared with facial paralysis with RD, due to compression or severe degeneration of the nerve.

The occurrence of the RD proves a lesion of the lower motor neuron of the nervous system, consisting of the anterior horn cell, anterior root and nerve plexuses, and peripheral nerve. Clinically, such a lesion is always accompanied by flaccid paralysis and loss of tendon reflexes.

Functional, hysterical paralysis or cerebral origin are never accompanied by important disturbances of the electrical reactions. At most there is slight electric hyperexcitability, while in the later stages there is usually hypoexcitability, from muscular disuse. The presence of normal response can be demonstrated before a jury and thus malingering effectively disproven.

The presence of an RD may be a deciding factor in diagnosis, but it is not infallible. It must always be considered in conjunction with other clinical evidence. For instance, in the case of multiple injuries of the extremities, especially of the forearm, one cannot make a diagnosis on the basis of electrical testing alone. There may be loss of response of several muscles, following extensive scar formation after longitudinal incisions or infectious processes, and a nerve lesion imitated. The coexistence of adhesions binding down tendons may exaggerate a nerve lesion or may make it appear more extensive. In paralysis of traumatic origin electrical testing cannot determine, without a thorough clinical examination, whether the paralysis is caused by the original trauma or secondarily by contracting scars or pressure of callus. Neither can it determine whether the nerve is torn or cut or simply bruised or stretched.

The technique of electrical muscle and nerve testing can be fairly easily acquired. A set of testing charts is indispensable for the beginner, because it shows the location of the motor points, the areas where the least amount of stimulation will bring about response in the easiest manner. One must remember that in the presence of the reaction of degeneration, the motor points of muscles are displaced distally—toward the tendon—and at the same time the motor point of the nerve disappears entirely, i.e., no response can be elicited through stimulating the nerve.

Every physician who has occasion to treat nerve injuries must be familiar with the faradic and galvanic test. Unrecognized and unskillfully treated nerve injuries are responsible for permanent maiming following many industrial accidents, and therefore there ought to be no delay in the early recognition and appropriate treatment of such injuries. It is similarly important to recognize simulated cases of paralysis following accidents. A physician skilled in the simple method of electrodiagnosis can testify as an expert and, when necessary, demonstrate his findings in court.

LOW FREQUENCY CURRENTS

The principal employment of the currents of low tension and low frequency in traumatic conditions consists in the treatment of the various degrees of muscular weakness and paralysis following simple disuse or peripheral nerve injuries.

Muscle when not used atrophies; exercise, on the other hand, leads to increase in size, strength and tone. Atrophy of disuse is due to alteration in character or intensity of normal metabolism. In the absence of RD and in simple muscular atrophy the problem of treatment is comparatively simple and resolves itself mainly in providing suitable exercise, voluntary or artificial, to restore the strength and tone of muscles. The surging

faradic or the interrupted or surging sinusoidal current appear to be equally effective when active voluntary exercise is not convenient. It is essential that any form of electrical stimulation be used with periods of alternating flow and rest, so as to allow alternate play and relaxation of the muscles. Experiment and clinical evidence shows that rhythmically varying currents are most effective. For all these reasons neither the ordinary faradic nor the interrupted galvanic current are to be used as routine measures in treatment, because the first causes tetanus, the second single shocks. No electrical treatment should be given at a strength or duration which is painful or leaves the muscles in an exhausted state. Best results are achieved by carefully individualized technique.

Technique—If the muscles of an extremity are all nearly evenly affected, the bipolar technique or treatment en masse can conveniently be employed. Two electrodes of suitable size are placed at the opposite ends of the extremity; for instance: one electrode under the buttocks, the other under the sole of the foot. The surging current passing along the entirely extremity results in a fairly even contraction of all muscles, provided that their response is about equal. Due to the alternation of the surge, the polarity effect is usually more prevalent on one side of the extremity, and hence the almost uncanny alternating contraction of the flexor and extensor groups. Treatment is started at five to ten minutes and gradually increased according to response. There never should be more current used than is necessary to bring about a perceptible contraction.

The unipolar or motor point technique of muscular stimulation is the method of choice when only a few muscles need artificial stimulation; it allows regulating the current strength in accordance with the needs of each individual muscle. A small active electrode about one inch in diameter is placed over the motor point of each muscle to be treated, while a large dispersive electrode is placed over the sternum or the spine. One should start with a few contractions to each muscle and increase it to a maximum of two to three minutes treatment. This technique takes more time and requires the individual attention of a trained operator.

Electrical treatment for simple muscular weak-

ness or in functional paralysis resulting from trauma must always be combined with active voluntary exercise and abandoned in favor of the latter as soon as there is sufficient active response. It is advisable to have the patient attempt voluntary contraction while the current is on, and it will be often possible to cut down gradually on the current and let the patient do all the work. Proper support of the weakened muscles in a relaxed position, avoidance of overstretching by the healthy antagonists is essential.

In real paralysis with a full RD the situation is much more complicated and it is not possible to go into all its aspects in the limited space of this paper. So far as electrical stimulation is concerned, its object is to cause movements similar to normal ones, thus helping to preserve part of the functional properties of the muscles until normal nerve impulse returns. Contractions of any sort exert massage effects and help to prevent fibrous formation within the degenerated muscle. If only part of the muscle is fully paralyzed, contractions exercise and strengthen the non-paralyzed part and may enable it to do compensatory work.

The slow (galvanic) sinusoidal is the current of choice to which paralyzed muscles respond best. The unipolar or motor point technique is preferable and a current strength just enough to bring about a flicker of the tendon is all that is necessary. The danger of over-exercise and the tiring out of the affected muscles is always present, especially when the muscle is just about to regain active power. Previous to treatment, the muscles should be warmed up by luminous heat or diathermy, and during treatment they must be relaxed. Proper splinting from the very beginning is most important for the prevention of overstretching by the antagonists. It shows an appalling lack of the elementary principles of muscle treatment when one sees a patient with a radial paralysis going around for weeks with the hand dangling down from the wrist. A few minutes of electrical treatment, even if given daily, cannot make up for the damaging effect of continuous overstretching by the powerful flexors.

The correct technique of the application of the enumerated can only be acquired by actual clinical work under an experienced medical teacher.

NEW YORK STATE JOURNAL OF MEDICINE

Published semi monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication

THE FALL JOURNAL

The Summer season is vacation time for the Medical Society of the State of New York and its constituent Societies, as well as for their individual members. It has always been the policy of this Journal to record Society activities as soon as possible after they occur. The result has

been that the News Department of this Journal has had little to record during the Summer months; but the news in this issue fills six pages as the department resumes its normal size and interest and thereby reflects the renewed activities of the Societies.

THE COMITIA MINORA

Why are some county medical societies progressive and influential, while others are conservative and inactive? The answer involves two conditions:

1. The temperament of the individual members.
2. The methods of conducting the work of the organization.

A county medical society is a group of doctors brought together by the accident of their geographic location. When ten, or fifty, or five hundred doctors are brought together there will be many types of temperaments,—the theoretical and the practical; the public-spirited and the individualistic; the extrovert and the introvert. These temperaments have nothing to do with the character of a physician, although they are often the basis of personal quarrels in the county societies. The most upright doctor, for example, may be an innocent cause of a division in a county society by insisting on a perfectly proper line of action which is opposed by his less informed brethren.

Temperaments become evident when a disputed subject is debated in a county society meeting. The subject of free clinics, for example, is sure to promote a contest between some young progressive member and an older conservative. One member takes a progressive attitude because it is his temperament with which he was born; the other member may be conservative because his thyroid gland is small. Suppose, for example, a popular lecture on cancer is proposed, the progressives will be for it and the conservatives against it; and a great deal of evidence will be needed to convince either party of the merits of the other.

How can a county society conduct a discussion or debate so that the progressives and the conservatives will work together in harmony? Every

new activity is an evolution or a growth for which the soil must be prepared, the seed sown, and the tender shoots nurtured before it becomes self-sustaining. If the proposal for a new activity is thrown into a formal meeting of a county medical society, it will be torn to pieces by debaters who speak off-hand in the light of their inherited temperaments and experiences. The medical examination of school children, for example, is a subject that often brings to light the specter of State medicine to frighten both the progressives and the conservatives.

The larger county medical societies are demonstrating a practical way of getting work done which will avoid ill feelings, by the method of discussion and decision by a committee before the subject is debated in a meeting of the society as a whole. A half dozen members, both proponents and opponents of a measure, conversing informally and considering actual conditions and needs, will be sure to reach a unanimous agreement; and when the committee reports, the society will support its recommendations, for it will feel that all phases of the subject have been considered.

The smaller county societies sometimes fail to appoint the necessary committees on the ground of the lack of personnel, but there is one committee,—the *Comitia Minora*,—that is the executive committee of the whole society. That committee can secure harmony and promote progressive activities if it will meet frequently, and will take a definite stand on every proposition that is brought before the society. The members of the *Comitia Minora* can investigate and discuss a condition without prejudice or fear, and can take time to formulate a plan of action which has been evolved by careful consideration and thought.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Medical Legislators:—The suggestion is often made that more physicians should seek election to legislatures and the national Congress. This Journal of October, 1907 describes conditions in France as follows:

"There are ninety-two physicians in the present French Congress, while there were four physicians in the two houses of the last Congress of the United States. The population of France is 38,228,969, while that of the United States is 85,000,000. The number of physicians in the United States is 122,167. The French Congress, like the American Congress, is composed of two houses. The upper house in France, like that in this country, is called the Senate, while the lower

house, corresponding to our House of Representatives, is called the Chamber of Deputies. The French Senate has 300 members, of which forty are physicians; the American Senate consists of ninety members, of which one is a physician. The French Chamber of Deputies has 595 members, of which 52 are physicians; the American House of Representatives has 386 members, of which, in the Fifty-ninth Congress, three were physicians. The interest which medical men in France display in matters of state cannot be accounted for on the basis of compensation. The pay, or the 'indemnity,' is only about \$1,800 for both senators and deputies, while the pay in the United States is \$7,500, in both branches of Congress."

MEDICAL PROGRESS

Experimental Articular Rheumatism — F Gudzent says that in 1926 he first called attention to the fact that, just as in gout, so in a certain group of cases of rheumatism, the clinical signs suggested an allergic reaction to certain components of the diet. Later he reported on a number of rheumatic patients in whom tests revealed a sensitiveness to eggs and fish and who showed great improvement when these foods were excluded. Doubt having been cast upon his conclusions regarding the relationship of allergy to rheumatism, the writer instituted a number of experiments upon rabbits to prove or disprove his theory. He first prepared a number of strongly albuminous extracts of a great variety of foodstuffs, and then injected from 2 to 4 cc of these extracts into the rabbits (of course only one into each rabbit) and repeated the injection in a week or ten days. Then after an incubation period of 3 to 4 weeks each rabbit received an injection into a joint of $\frac{1}{2}$ to 1 cc of the extract to which it had been sensitized. In about 24 hours the joint became swollen and presented inflammatory symptoms. Control animals showed no reaction. The extracts were thoroughly sterilized before injection. The inflammatory swelling subsided after a few days but reappeared whenever the injection was repeated, and often returned after a while even when no injection was given. The symptoms were very similar to those of acute inflammatory rheumatism. The author believes the results of these injections would warrant further experiments to determine what relationship, if any, exists between allergy and articular or muscular rheumatism.—*Deutsche medizinische Wochenschrift* July 22, 1932

Treatment of Megacolon by Parathormone — Luther Sheldon, Richard A. Keen, and Eric G. Hakansson report in the *American Journal of the Medical Sciences*, July, 1932, three cases of which the following are summaries:

CASE I A man, 32 years old, had developed at the age of 18 chronic constipation. The trouble increased constantly in severity and examination at the age of 27 years revealed the presence of a hugely dilated colon. He had had no bowel movements for 10 years without large doses of laxatives and enemata. Treatment with parathormone and calcium lactate was begun, in the second week the man had one natural passage and in the third week his bowels began to move daily without laxatives or enemata. Several courses of treatment were given, the con-

stipation returning when they were discontinued but bowel movements becoming normal in two or three weeks after the resumption of treatment.

CASE II A woman, 59 years old, had had increasing constipation, abdominal distention, an cramps for about two years. A sudden increase of trouble led to a diagnosis of acute colonic obstruction and an emergency cecostomy was performed. The laparotomy showed a greatly dilated colon. Parathormone injections resulted in a return of normal bowel movements, but when the dosage was greatly reduced at the end of three months the symptoms recurred. However, under increased parathormone dosage normal bowel movements were reestablished and a week later the entire large bowel was shown to have been reduced to practically normal size.

CASE III A man, 65 years old, developed in 5 weeks an adynamic ileus of unknown origin. The chief findings were abdominal distention, a capacious atonic colon, and a lowered serum calcium level. Parathormone injections were followed by a return of normal bowel movements with relief of symptoms and a return to normal of the serum calcium.

In review the authors discuss the possible relation of abnormal parathyroid function to disorders of intestinal motility and to megacolon. Further studies are suggested to determine the possible danger to the patient from prolonged parathormone administration.

The Tannic-acid Treatment of Burns and Scalds — W. C. Wilson gives his experience of over two hundred cases of burns treated by applications of tannin as advocated by Davidson. All burns, if more than superficial or of slight extent, should be treated in hospital. The burned area is cleansed under general anesthesia, preferably nitrous oxide and oxygen. All loose epithelium, especially at the edges, is carefully removed and then the raw surface is gently swabbed with ether or alcohol followed with a 1:1000 solution of bichloride of mercury. A coagulating solution is then sprayed, every hour for seven to twelve hours, over the surface and dried by a current of hot air. This consists of an aqueous solution of 2.5 per cent tannic acid in 1:1000 acriflavine. No subsequent local treatment is necessary, the part being protected by a cage in which are hung some electric light bulbs for warmth. In cases of deep burns, if signs of sepsis appear it will be necessary to remove the coagulum preferably by cutting it away with scissors, possibly under general anesthesia. The area is then treated as an infected wound. If the temperature rises it will be advisable, and sometimes

imperative, to stop the application of external heat by the electric bulbs under the cage. Throughout the treatment a copious supply of fluids is called for, if necessary by the intravenous injection of saline solution in addition to the fluid given by the mouth or rectum.

When, in the absence of hospital facilities, home treatment is obligatory, the burned area is to be cleansed in the above-described manner and then gauze soaked in the coagulating solution applied to the raw surface and covered with cotton-wool and a bandage. After 12 to 24 hours the dressing is removed and the coagulum dried by exposure to the air and then covered with a protective dressing of dry gauze and a bandage.—*The Practitioner*, July, 1932.

The Development of the Cardiovascular-Renal Syndrome.—R. E. Horsfall says that, included in the exorbitant price mankind pays for the doubtful blessings of civilization, prominent is the symptom-complex of raised blood-pressure, arterial and myocardial degeneration, and renal inadequacy. In analyzing the etiology and chronology of this syndrome, we have to ask ourselves: "Is the arteriosclerosis the cause or the sequel of the nephritis? Is the myocardial damage secondary to the arteriosclerosis, or are they both due to a common causal factor?" Assuming the presence of a circulating toxin, either endogenous or exogenous, (1) arterial hypertrophy and subsequent degeneration may result from direct action of the toxin on the vessel walls or from prolonged toxic vaso-constriction. This causes a rise in blood pressure leading in some cases to renal sclerosis with albuminuria, casts, and perhaps nitrogen retention. (2) Chronic interstitial nephritis may occur first with compensatory rise of blood pressure leading to arteriosclerosis, or with an accumulation of toxic metabolites in the circulation causing arteriosclerosis and rise of blood pressure. The hyperpiesis may affect the heart in three ways: (1) It may cause aortic atheroma leading to stenosis of the openings of the coronary arteries with reduced blood supply and fibrosis of the myocardium. (2) It may cause chronic endocarditis of the aortic valves with stenosis of the coronary orifices. (3) There may result a compensatory hypertrophy of the myocardium with eventual degeneration. Finally, the circulating toxin may damage the cardiac muscle directly, or indirectly, by sclerosing the coronary arteries.—*The Practitioner*, August, 1932.

Symptomless Coronary Thrombosis.—Frewen Moor and Herbert Rogers report an unusual case of a man 70 years old who died suddenly while sitting at a table writing. One of the reporters was his family physician but had seen him seldom and he had never complained of any illness. Careful inquiry from his relatives and

friends had failed to elicit any symptomatic history. He never complained of pain and what moderate shortness of breath he had was attributed to his age. His appetite was good and his wife had never thought him to be below par in any way. His habits were good except that he was an immoderate cigarette smoker, never being without a cigarette in his mouth. (The writers quote Levine, parenthetically, as mentioning smoking as one of the possible causes of coronary thrombosis.) At the autopsy the pericardium was found to contain about an ounce of clotted blood. The heart was normal in size, but there was an aneurysmal dilatation, half an inch across, on the posterior surface of the left ventricle, over which there was some patchy thickening of the pericardium, rupture at this point being the cause of death. The coronary arteries showed gross senile degenerative changes. The anterior descending branch of the left coronary was converted into a rigid calcified tube with the lumen irregularly diminished in size but nowhere completely occluded. The circumflex branch passing down the posterior aspect of the left ventricle, was almost occluded at a point one inch from the auriculoventricular groove, just below which thrombosis had taken place and had resulted in infarction of the myocardium. The right coronary artery displayed patches of atheroma. The aortic and mitral valves were slightly thickened. Microscopic examination confirmed the naked-eye appearances but raised the probability that some months must have elapsed between the initial thrombosis and the fatal termination. Such a condition might have existed without causing pain, but it was remarkable that there were no symptoms, local or general, to arouse suspicion of any cardiac disorder.—*British Medical Journal*, August 6, 1932.

Infranodal Heart Rhythm Produced by Exercise.—Harald A. Salvesen reports a case of this nature in *Acta Medica Scandinavica*, July 23, 1932. The patient was a man, 52 years of age, with a rather poor previous history (coxitis at 5 years of age, operated upon, the patient being kept in bed for several years; albuminuria, lasting for several years, at 15; and left-sided pleurisy at 30 years). He began to be troubled with occasional palpitation and irregularity of the heart beat three years ago. The electrocardiogram at rest showed a slow sinus rhythm without any sign of block, but after a certain amount of exercise there was always an infranodal rhythm. As the ventricles slowed down the auricles kept up their former speed; there being for a short time complete dissociation between auricles and ventricles; this dissociation always occurred when the ventricular rate fell below 70, there being then for a very short period an interference between the sinus and the atrioventricular rhythms. Quinine and quinidine had no effect

on the abnormal rhythm. The author regarded the condition as one of partial sinoauricular block made complete by the increased heart beat after exercise.

The Role of Fatigue in Digestive Disorders.

—Frederick G. Speidel says that the first question arising in a discussion of this subject is the cause of fatigue. It may be said confidently that it is not a result of the depletion of available stores of glycogen or other combustible material in the muscles. The results of attempts to circumvent fatigue by the administration of sugar were not encouraging enough to warrant a general adoption of the method. The accumulation of the waste products of metabolism has been advanced as a cause of fatigue. Such an accumulation might conceivably cause a decrease in the responsiveness of muscles to stimulation but the theory has yielded no therapeutic results. Studies of the fatigue of the reflex arc have, however, had important results. That the sensory receptors can be experimentally fatigued has been demonstrated repeatedly. The cell body of the neuron shows definite alteration in staining characteristics as a result of severe muscular fatigue and it may be argued that such alteration indicates a temporary inhibition of function of the affected cells. The effect of tonic doses of strychnine in relieving the sense of fatigue, coupled with the known fact that strychnine lowers the synaptic resistance, justifies the belief that at the synapse is the point of the neuromuscular system where fatigue first occurs. The bodily changes accompanying fatigue are similar whether the fatigue be due to overactivity of the somatic or of the mental functions. These changes are adjustments which are necessary if it become imperative that activity continue. They consist in general of abolishing all functions that are not concerned in the movements of the limbs or in transporting the body from place to place. The intellectual functions are inhibited, the sex functions are held in abeyance, the secretion of saliva, of gastric, intestinal, and pancreatic juices, and of bile ceases and the motility of the stomach and intestines is abolished. The significance of this sequence of events becomes apparent when it is recalled that it is just at this particular time that the tired individual eats his evening meal, the largest of the day, and it is hardly conceivable that the meal can be properly digested under these conditions. The association of fatigue and digestive disturbances is observed often enough to indicate a causal relationship. Physician and patient often attribute the weariness felt at this time to absorption from the digestive tract of toxic products of incomplete digestion, but it is more rational to attribute the faulty digestion to an underlying fatigue of psychogenic origin. That the remedy for this fatigue does not consist in more rest is evident. Change of scene, varying

one's occupation, and diversification of interests all suggest themselves and all are in many cases impossible of realization. The most generally applicable and effective method of ameliorating fatigue in these cases, the author holds, is to induce the tired individual to allow himself to be actuated in the performance of his daily tasks from hour to hour by a number of different, appropriate, consciously aroused, dynamogenic motives. In this manner an almost infinite number and variety of synaptic connections must be utilized and no circumscribed area will reach that degree of resistance that induces the feeling of fatigue. —*Southern Medical Journal*, September, 1932.

A Non-operative Treatment of Carbuncles.

—William A. White, Jr., and Edward A. Cooney, writing in the *New England Journal of Medicine*, September 1, 1932, give an account of a non-operative treatment of carbuncles employed with most gratifying success in 20 per cent. of over 500 cases treated at the Boston City Hospital during the four years ending in November, 1931. The method is essentially one of permitting the lesion to run its course aided by non-specific foreign protein therapy. Sir James Paget, over 60 years ago, made a plea for the non-operative treatment of carbuncles, after an experience with more than 200 cases, from which he drew the following conclusions: (1) Incision does not prevent extension; (2) it fails to allay pain in most cases; (3) the process of healing is not hastened. Various forms of conservative treatment have been practised: heterovaccination, specific and autogenous vaccines, autogenous blood injections, roentgen-rays, violet rays, Bier's vacuum hyperemia, ionization, the high frequency current, etc. The authors regard a carbuncle as a kind of cellulitis eventuating in central necrosis and slough. The first stage is one of subcutaneous cellulitis (the first evidence of which is a small pustule surrounded by a painful red induration) with edema of the edges. After a few days the pain subsides and there is central necrosis followed by liquefaction and discharge of slough and pus. The third stage is one of cicatrization and healing. The writers employ a nonspecific protein therapy which favorably activates cell stimulation and increases the specific protective bodies. The spread of infection is thereby checked, pain is relieved within two to eight hours, and healing is hastened. They report four cases in which this simple technique was used with most satisfactory results. The local treatment consisted in the application of hot chlorinated dressings and flaxseed dressings. Aolan, activin, and ommadin were variously selected for the daily nonspecific protein injections.

Atheroma in Rheumatic Heart Disease.

—Pearl Zeek, writing in *The American Journal of the Medical Sciences* for September, 1932, reports

on the results of 3,372 autopsies in cases of rheumatic fever. Of these, atherosclerotic lesions were found in 62—36 males and 26 females—ranging in age from 7 to 66 years, but most of them under 40 years. Generalized sclerosis was found in only 15 cases. Questions which are left open are: "Why do atheromatous changes occur particularly in mesodermic tissues?" and "What does rheumatic disease have in common with the relatively few other conditions which are found to predispose to the early development of atherosclerosis?" In conclusion it is stated that rheumatic heart disease predisposes to the early development of atheromatous lesions in the aorta, pulmonary artery and coronary arteries, and in the valvular and left atrial endocardium. Lipoid deposits have also been found, in some cases, in the inflamed serous membranes and in certain renal tubules. Lipoid deposition seems to begin soon after the onset of cardiac disease, and in a very general way seems to parallel in degree the cardiac lesions. The atheromatous changes in many cases are progressive, leading to calcification and, when in the valvular endocardium, to accentuated stenosis.

Differential Arterial Tension.—E. J. Stieglitz and D. W. Probst accept for this term the definition of Cyriax that it is the difference in readings of the arterial tension on the two sides of the body. Because of the meagerness of the available data regarding the incidence of asymmetry of the arterial tension the authors studied it in six hundred cases. In these asymmetry was found in slightly over 15 per cent. They think it probable that in the majority of cases it is essentially transient, but it tends to be recurrent. When persistent it is likely to be due to some organic lesion such as aortitis, cervical rib, atrophy or some other trophic disorder. Asymmetry of the arterial tension is more frequently encountered in patients with hypertensive disease than in those with normal blood pressure, but there is no sex predominance. Elevation of systolic and diastolic tension is somewhat more frequent on the right side than on the left. It has in most cases a distinct clinical significance and failure to determine the blood pressure on both sides may result in serious diagnostic error. Arteriolar spasticity, cervical rib, aortitis, injury of an extremity with atrophy, arteriovenous aneurysm, and central trophic disturbances, such as occur in tabes dorsalis, are all factors to be considered in evaluating the causation of persistent asymmetry.—*American Journal of the Medical Sciences*, September, 1932.

The Clinical Significance of Heart Murmurs in Hyperpiesis.—Max Hochrein says that all writers on high blood pressure mention the occasional occurrence of cardiac murmurs at the apex or base, but very little attention has been given to the mechanism or the clinical significance of

those sounds. A basal murmur at the beginning of the diastole is an early symptom of insufficiency and is of service as an indication of the condition of the general circulation, upon the realization of which the success of treatment may depend. Mitral murmurs in cases of hypertension are not, as were formerly generally thought, merely accidental and of no special significance, for in 20 per cent. of the 162 cases studied by the author they were found at autopsy to have been an expression of organic mitral lesions. These constitute a special group of high tension cases of which the following are characteristic signs: Mitral murmurs, lessened vital capacity, absolute arrhythmia, lengthening of the P Q event and duplication of P. As a result of energetic treatment, which is to be instituted when there are no decompensation symptoms, the pressure falls quickly to normal. The mode of origin of the hypertension is not always clear in these cases but probably it is a reflex process. An early recognition of this symptom complex is important, for by treatment with strophanthin and digitalis the prognostically unfavorable secondary stage of the high blood pressure may be lessened or avoided altogether.—*Münchener medizinische Wochenschrift*, August 12, 1932.

Allergic Anginoid Pains.—Paul Veil writing in *Archives des Maladies du Cœur*, etc., July, 1932, refers to two cases of this nature reported in the March issue of this same journal, and adds the histories of two additional cases in the present article. The first of these was that of a woman 60 years old, prematurely aged, short of breath, with a chronic cough, and complaining of a violent parasternal pain. The only event in the previous history was a non-traumatic hydrarthrosis of the left knee which disappeared in time leaving a painful joint which the patient was obliged to keep bandaged. In 1929 she began to experience oppression in the chest at night and difficult breathing in the day, made worse by walking and especially stair climbing. This was followed by severe attacks of coughing resembling pertussis. Still later very severe pain was felt in the precordial region radiating to the left arm. Auscultation of the lungs gave no information and that of the heart was also negative. More careful questioning elicited the information that the patient suffered from indigestion and could not tolerate eggs or milk. The blood pressure was found to be high, especially during the crises of anginoid pain. A desensitizing diet (abstention from milk and eggs) was ordered, and when the patient was seen a year later she was in perfect health, with normal blood pressure, no cough nor dyspnea, and free from parasternal pain. The case was evidently allergic in character for, as in the others reported, relief followed promptly on the exclusion of the offending materials from the diet.

LEGAL

ACTIONS FOR DEATH BY WRONGFUL ACT—RIGHT OF ADVERSE PARTY TO PARTICIPATE IN AUTOPSY

By LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

Has a person who is or has reason to believe that he will be a defendant in a personal injury action based upon death by claimed wrongful act, the right to be present at a private autopsy performed upon the deceased person by request of those who have or who are about to commence such action, where it can be shown that the findings and conclusions upon such autopsy are material to the pending or contemplated litigation? The answer to this interesting and important question was furnished by a decision of one of our Appellate Courts some years ago. Before reviewing the facts in that case and ruling of the court, let us examine Section 5-a of the Public Health Law. This Section provides as follows:

"*Regulation and control of autopsies.* The commissioner of health shall prescribe and prepare the necessary methods and forms for obtaining and preserving records and statistics of autopsies which are conducted by the coroner or by his order within the state of New York, and shall require all those performing such autopsies, for the purpose of determining the cause of death, to enter upon such record the pathological appearances and findings embodying such information as may be prescribed, and to append thereto the diagnosis of the cause of death, and a copy thereof shall be duly filed, within ten days, with the coroner of the county in which such autopsy shall be held, and a transcript thereof shall be filed, within ten days thereafter, by the coroner, with the state commissioner of health, and it shall thereupon become a matter of public record which shall be open to the inspection and transcription of and by one affected or likely to be affected, in a civil or criminal action, by its contents, upon an order of a court of record or of a justice of the supreme court. It shall be the duty of any surgeon performing such an autopsy, under the provisions of this section, to permit the attendance, as a matter of right, of a person, or the medical representative of such person, likely to be the defendant or representative of such deceased person in a civil or criminal action, of which such autopsy and its findings and conclusions may prove to become a part, or in any way affected thereby."

It will be noted that under this Section the physician performing the autopsy on behalf of the coroner must permit, as a matter of right,

the attendance of a person or the medical representative of such person who is likely to be the defendant or representative of such deceased person in a civil or criminal action in which the autopsy and its findings and conclusions may prove to become a part or in any way affected thereby.

In the case under review, a woman during her lifetime commenced an action to recover damages for personal injuries which she claimed to have received in an automobile accident alleged to have been caused by the negligence of the defendant. While the action was pending, the plaintiff died. Several days later a petition was presented to the Supreme Court on behalf of the defendant alleging, in addition to the facts already stated, that an action was about to be brought against the petitioner by the representatives of the deceased woman for damages for her death, based upon the claim that her death was caused by the negligence of the petitioner in such automobile accident. The petition further stated that a physician employed by the petitioner had examined the woman during her lifetime and had reported a complete recovery of any injury she might have received in the automobile accident. The petition further stated that the woman's death was caused by inflammation of the liver, and that on the day of her death an autopsy had been performed which showed that death was due to such disease, and that to ascertain the cause of death an examination of that organ was necessary. It was further stated that that organ had been removed from the body at the autopsy and was in the possession of either the attorney for the plaintiff or the surgeon who performed the autopsy, and that the petitioner had been informed by the attorney for the woman that an examination was to be made of the organ, but permission was refused the petitioner or his representative to participate in the examination, and the attorney for the deceased woman also refused to disclose the findings or results on such examination.

Upon this petition an order was secured from the Supreme Court calling upon the personal representatives of the deceased woman to produce forthwith for examination by the defendant the portions of the body of the deceased woman desired to be examined, and more particularly the liver, for the purpose of having the same ex-

amined by the medical representative of the defendant. A motion made by the representatives of the deceased woman to vacate this order was denied, whereupon an appeal was taken to the Appellate Division. Upon appeal the order below was reversed, the court holding that the Section of the Public Health Law above quoted related solely to official autopsies; that is, those performed by or under the direction of the coroner, and were not applicable to private autopsies, and hence neither the defendant nor his medical representative was entitled to participate in the autopsy or permitted to see the findings or conclusions. The court made the additional point that the order below related mainly not to the autopsy, but to an examination of the viscera. In its opinion of reversal the court said:

"The provisions of section 5-a of the Public Health Law (as added by Laws of 1913, Chap. 620), relied upon by the respondent as a basis for the order, which allow the medical representatives of a person likely to be a defendant in a civil action to be present at certain autopsies,

has no application to this case. That section relates to what may be termed official autopsies, that is, those performed by or under the direction of the coroner. This autopsy was private and not performed or ordered by a public officer. Further the order in this case in no way relates to an autopsy but to an examination of a portion of the viscera, a matter not covered by the statute. Neither is the order justified by section 803 of the Code of Civil Procedure (Civil Practice Act, Sec. 324) as the discovery there provided for can only be required at the instance of a party to an action, while in this case no action was pending. Nor has the respondent cited any other authority supporting the original order. Although in this instance, the organ seems to have been removed from the body at least temporarily, it was still a part of the human remains and as such was to be decently disposed of as the family might desire. In the absence of clear right or statutory command, the courts should not interfere with the relatives' possession or control of the remains or any part of them."

SUN-RAY BURN

A middle-aged woman consulted a general practitioner, complaining of a cold, cough and pains in her back. The doctor took her pulse, temperature and blood pressure and examined her chest and back with a stethoscope. He diagnosed a cold with a slight condition of bronchitis. He told the patient that he would either give her medical treatment or treatment with the sun-ray lamp. The patient decided upon the sun-ray lamp and the doctor seated the patient on a treatment chair and administered to her a treatment with his mercury vapor lamp. The apparatus was fixed at a distance of twenty-four inches from the plaintiff's chest which was exposed to the rays for about ten minutes. He then similarly exposed her back to the lamp for about fifteen minutes.

At the end of the treatment the doctor explained to the patient that some people show an idiosyncrasy to such treatment, depending upon the sensitiveness of the skin, and that the reaction to the treatment would probably vary from a slight redness to a redness similar to a sun-burn, and he warned the patient that she should not be surprised if such a reaction developed in her case. The patient was of a dark complexion

and showed no evidence of having a sensitive skin.

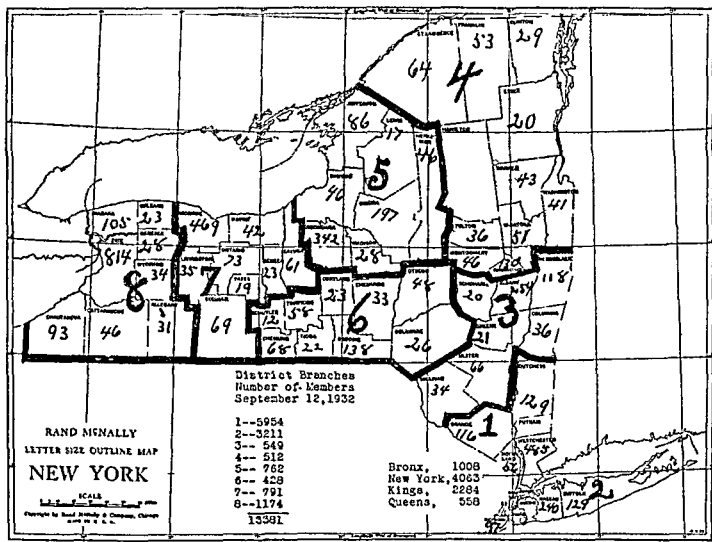

A few days later the patient returned to the doctor's office with a reaction from the sun-ray on her back, a large area having the appearance of a sun-burn with a few blisters. The doctor prescribed an ointment to be applied to the burn. The patient never returned to him for other treatment.

The patient sued the doctor to recover damages based upon alleged malpractice. The charge of negligence contained in the complaint was that the defendant was unskillful in treating the plaintiff by exposing her bare back to the strong rays of an electric current and leaving her unattended for a period of about one-half hour, and failing to supply a nurse's services while the plaintiff was exposed to the electric current, as a result of which it was claimed that the plaintiff's entire back was caused to become blistered.

The action was called for trial in its regular order on the calendar and no one appearing to prosecute the matter on behalf of the plaintiff, and on motion of defendant's attorney the action was dismissed and the case terminated in favor of the defendant.

NEWS NOTES

MAP OF THE DISTRICT BRANCHES OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The figures indicate the number of members of the County Medical Societies on September 12, 1932

THIRD DISTRICT BRANCH

The first of the meetings of the District Branches of the Medical Society of the State of New York, of the year, was that of the Third District, composed of seven counties stretching from Albany diagonally across the State to Sullivan County on the southern border. These county societies have a total of 549 members. The meeting was held on Wednesday, September 21, 1932, from 10 a.m. to 3 p.m. in the Loomis Sanatorium in Liberty, Sullivan County. The president, Dr. H. L. Odell of Sharon Springs, presided, and 65 doctors were in attendance. A noon luncheon was served by the courtesy of the Sanatorium.

The scientific program consisted of six addresses given simply and briefly, and in a conversational manner. The speakers and their subjects were as follows:

Bronchoscopy in the Diagnosis of Thoracic Disease, by Arthur F. Holding, M.D., Albany.

Trends in Modern Treatment of Tuberculosis, by J. Burns Amberson, Jr., M.D., formerly Superintendent of Loomis Sanatorium, and now

Assistant Professor of Clinical Medicine, College of Physicians and Surgeons, New York.

A Clinical Study of Tuberculosis Cavities, by B. T. McMahon, M.D., Associate Physician, Loomis Sanatorium, and E. H. Kerper, M.D., Roentgenologist.

The County Health Unit, by Thomas Parran, Jr., M.D., Commissioner of Health, State of New York.

The Endocrinological Problems in the General Practice of Medicine, by Max A. Goldzieher, M.D., Brooklyn, N. Y.

Officers were elected as follows:

President: Clark G. Rossman, M.D., Hudson, N. Y.

First Vice-President: Luther C. Payne, M.D., Liberty, N. Y.

Second Vice-President: A. J. Hambrook, M.D., Troy, N. Y.

Secretary: William M. Rapp, M.D., Catskill, N. Y.

Treasurer: Ernest E. Billings, M.D., Kingston, N. Y.

After the noon luncheon President Odell introduced representatives of the State Medical Society. Dr. Frederick H. Flaherty, President-elect, brought the greetings of the officers of the State Society, and complimented the speakers on the morning program.

Dr. J. N. Vander Veer made a plea that the County Medical Societies give serious attention to the activities promoted by the State Society.

Dr. Frank Overton, Executive Editor, called attention to the function of the NEW YORK STATE JOURNAL OF MEDICINE as the repository of the records of the State and County Societies, and the means by which the officers and committee-

men inform the officers and members of the County Medical Societies of the activities and policies of the State Society.

After the meeting the physicians were conducted through the Loomis Sanatorium by members of the staff of physicians. The Sanatorium was founded in 1906 as a memorial to Dr. Alfred Lee Loomis, Professor of Medicine in the Medical School of the New York University, who was a leader in the care of tuberculosis patients in New York City. It has a capacity of 225 beds, and while it is a private institution, it does research work of the highest type, and its methods are accepted as standards for the diagnosis and treatment of all forms of pulmonary tuberculosis.

SECRETARIES' CONFERENCE

The sixth annual conference of the secretaries of the County Medical Societies of New York State was held in the Hotel Ten Eyck, Albany, N. Y., on Tuesday, September 13, 1932, beginning at 10 A. M., with Dr. Peter Irving, Assistant Secretary of the Medical Society of the State of New York, presiding. The members lunched together at noon, and adjourned soon after 3 o'clock. Thirty county societies were represented, as follows:

Albany.....	H. L. Nelms
Bronx.....	I. J. Landsman
Broome.....	L. H. Quackenbush
Chautauqua.....	E. Bieber
Clinton.....	A. S. Schneider
Columbia.....	L. Van Hoesen
Cortland.....	A. E. White
Delaware.....	W. M. Thomson
Erie.....	L. W. Beamis
Genesee.....	P. J. Di Natale
Herkimer.....	W. B. Brooks
Jefferson.....	C. A. Prudhon
Livingston.....	G. M. Doolittle
Monroe.....	W. A. MacVay
Montgomery.....	W. R. Pierce
New York.....	D. S. Dougherty
Oneida.....	W. Hale, Jr.
Onondaga.....	E. E. Mack
Orange.....	H. J. Shelley
Rockland.....	W. J. Ryan
Saratoga.....	H. L. Loop
Schoharie.....	H. L. Odell
Suffolk.....	Frank Overton
Sullivan.....	L. C. Payne
Tioga.....	I. N. Peterson
Ulster.....	F. H. Voss
Washington.....	S. J. Banker
Westchester.....	A. F. Heyl
Wyoming.....	Klostemyer
Yates.....	G. C. Hatch

The following representatives of the State Medical Society were present:

Dr. F. H. Flaherty, President-elect.

Dr. D. S. Dougherty, Secretary.

Dr. T. P. Farmer, Chairman, Committee on Public Health and Medical Education.

Dr. Harry Aranow, Chairman, Committee on Legislation.

Dr. Frederic E. Sondern, Chairman Committee on Medical Research.

Dr. James Vander Veer, Past-President and Liaison Officer with the State Department of Health.

Dr. James Rooney, Trustee.

Dr. W. H. Ross, Past-President and member of the Committee on Public Relations.

Dr. J. S. Lawrence, Executive Officer.

Dr. Frank Overton, Executive Editor.

The State Department of Health was represented at the Conference by Dr. R. E. Plunkett, Director of the Division of Tuberculosis; and the Department of Education by Dr. W. A. Howe, Director of Medical Examinations of School Children, and Dr. W. P. Brown, his assistant in tuberculosis.

Fourteen topics were discussed briefly and concisely, and the conference ranked among the best in interest and practical value.

Object of the Conference: Dr. F. H. Flaherty, President-Elect of the State Society, explained that the object of the Conference was to clarify and unify the attitude of the county secretaries toward the standard activities which are promoted by the State Society and carried on by all up-to-date county societies. The expectation is that the secretaries will acquire the point of view of other societies, and be able to advise and direct their brother members in the light of the common experience throughout the State.

State Medicine Dr J S Lawrence described the methods of European countries in their administration of medical services by the government, and listed the following medical activities now administered by the State of New York

- Old age pensions
- Disability compensation
- Tuberculosis sanatoria
- Mental hospitals
- Subsidies to health officers
- Care of ex-soldiers
- Examination of school children
- Care of crippled children

Most medical activities controlled by New York State were conducted with the approval and co-operation of private practitioners, and are not in the class of compulsory socialized medicine as administered by European governments

Dr D S Dougherty, Secretary of the Medical Society of the State of New York, told of the controversy within the medical profession when health insurance of workmen was proposed, the cost to be divided between the employers, the workmen, and the State. The Medical Society of the State of New York opposed the scheme, and defeated it, although many public health leaders upheld the plan

Fireworks in Syracuse Dr Earle E Mack, Secretary of the Onondaga County Medical Society, told of the leadership of the Society in securing an ordinance prohibiting the sale of fireworks in the city of Syracuse on account of the serious accidents which occurred in 1931, from explosions and burns. The story of ordinance is told in this Journal of August 15, 1932, page 982

On motion of Dr Dougherty, the Conference approved the action of the Onondaga County Society, and a proposal to sponsor a State-wide law prohibiting the sale or use of fireworks except for public celebrations, under police control

Veneral Disease Clinics Dr W B Brooks, Secretary of the Herkimer County Medical Society, told of the opposition of the Society to any form of free public clinics, venereal or any other kind

Dr J N Vander Veer, Liaison Officer of the State Society in cooperation with the State Department of Health, outlined plans for instructing physicians in the modern treatment of venereal disease. He also emphasized the great need of instructing members of Boards of Supervisors in the economic phases of the treatment of venereal diseases in their early stages. The cost of curing a case of syphilis taken early is about \$200, while the cost of caring for in advanced case, crippled physically or mentally, is over \$1 000 annually

Dr Vander Veer said that the State Society would sponsor a graduate course of instruction in venereal diseases in any county that desired it. Talks on venereal diseases had already been given in 28 counties

Dr W H Ross told of the success of the Suffolk County Health Department in treating indigent venereal patients by paying the family doctors to give the treatments. During the last eight months the County Department of Health had approved the bills for 23 patients, at a cost of \$1,850

Health Lectures in Utica Dr William Hale, Jr, Secretary of the Oneida County Medical Society, described a series of health talks given to workmen in industrial plants in Utica during the noon hour. The project was first proposed by the Secretary of the Utica Y M C A, who secured the active support and leadership of the Oneida County Medical Society and acted as its agent in attending to the details of the lectures. The series was begun in 1929 in eight plants, while this year sixteen plants are opened to the doctors to lecture

The lecturers are appointed by the county medical society, and their names and subjects are announced in the newspapers. The subjects include such common conditions as colds, cinders in the eye, feet, teeth, periodic health examinations, minor accidents, and infections

There was some discussion on the subject of announcing the names of the speakers, on the ground of advertising them. But Dr Dougherty explained that the newspapers, the radio, and all other promoters of publicity demanded the announcement of the names of the speakers and writers. He said that the agreement in New York City is to announce the name of the doctor and one title, such, for example, as that he is the secretary of the county society

Dr T P Farmer, referring to the post-graduate lectures, said that in all the years that the courses had been given he had heard of only one complaint about the aggrandizement of a speaker

Tuberculosis Control in Monroe County Dr W A MacVay described the cooperation of the Monroe County Tuberculosis and Health Association with the County Medical Society, and told particularly of a joint meeting of the two organizations

On motion of Dr. Dougherty, the plan of a joint meeting was recommended to the organizations in other counties

Medical Examination of School Children Dr W P Brown, of the State Department of Education, described a study of tuberculosis among school children by the tuberculin test and the ray. This method disclosed tuberculosis a year or two before its presence was shown by symptoms

Dr William A Howe State Director of Medical Examinations of School Children, conducted a round-table discussion of the part to be taken by family doctors in examining pupils

Dr L W Beamis, Secretary of the Erie County Society described the "squad" system of

examining the school children of Buffalo, in which a group of specialists visited a school, and each child received the attention of each specialist.

Reporting Cases of Tuberculosis: Dr. R. E. Plunkett, Director of the Division of Tuberculosis of the State Department of Health, gave confidential information regarding the unsatisfactory attitude of some doctors toward reporting cases of tuberculosis, especially those of a mild type. Ignorance, fear and prejudice on the part of the patients lead them to resent the efforts of the doctors to treat them properly and to protect others from infection.

Anti-Vivisection: Dr. Frederic E. Sondern spoke of the growing strength of the anti-vivisectionists, and of the fear of research workers in universities that their work will be seriously hindered by law if the anti-vivisectionists adopt the method of securing a long list of names of petitioners, as they can do because of the financial endowments of their organizations. He asked the secretaries to be alert to calls for aid from the Research Committee.

Legislation: Dr. Harry Aranow, Chairman of the Committee on Legislation, said that the committee had two practical suggestions:

1. Secure a group of intelligent citizens to oppose unscientific health legislation.
2. Appoint a member of the county legislative committee from the town in which the legislator lives, in order to keep in easy contact with him.

Dr. E. E. Mack described a method adopted by the Onondaga County Society that each letter to a doctor requesting his action in legislation shall contain a stub to be returned to the chairman, showing that the member had complied with the request.

Maternal Mortality Study: Dr. Thomas P. Farmer, Chairman of the Committee on Public

Health and Medical Education, urged the secretaries to support the investigation into maternal mortality conducted by the State Department of Health, with the approval of the committee of the State Medical Society. He suggested that the public health committee of the county society be ready to arbitrate any dispute which may arise between an investigator and a family doctor.

Dr. Farmer said that his extensive contacts with officers of county societies had demonstrated the great desirability of retaining secretaries and committee members after they have become familiar with their work.

Cooperation With Governmental Officials: Dr. James E. Rooney, Past-President of the State Society, and now a Trustee, called attention to the evidence of progress shown by the number of State officials on the program of the Conference, —a condition unknown twenty-five years ago.

State Sanitary Code: Dr. Lawrence called attention to two amendments which have recently been made to the State Sanitary Code:

1. Requiring the examination of pathological specimens removed at operation, by approved pathologists.

2. Blood transfusions to be reported, with full data regarding both the donors and the patients.
- On motion, both amendments were approved.

Overlapping Investigations: Dr. W. R. Pierce, Secretary of the Montgomery County Society, made a protest against the number of medical investigations being made by lay organizations. Dr. J. N. Vander Veer reported that the Albany County Society had found fifty-one organizations engaged in health work in the county, with a resulting duplication of effort.

It was voted to suggest to the Committee on Public Relations the desirability of investigating overlapping public health efforts.

NEW REGULATIONS FOR CHANCROID, GONORRHEA AND SYPHILIS

Physicians may, after September 1, 1932, when reporting chancroid, gonorrhea or syphilis use numbers rather than names for identification of the patient. Numbers are permissible also on laboratory slips. However, physicians are required to keep a record giving the name and address corresponding to each number, which will be available to the local health officer. This radical change has been made in order to assure the physician and the patient of the sincerity of the Department of Health in keeping all information confidential.

The Social Hygiene Division of the New York State Department of Health is not interested in knowing who has these diseases,

provided that they are under medical supervision and are not conducting themselves so as to spread the infections. Physicians are requested to report all information including the name and address of any person discontinuing treatment while potentially infectious in the opinion of the attending physician. The Division of Social Hygiene will investigate, or cause to be investigated, all such cases; and if the patients can continue to pay for treatment, it will endeavor to have them return to their former physician; and if they cannot continue to pay, it will arrange for the treatment at the expense of the health district in which they reside.

The use of state nurses to follow up phy-

sicians delinquent cases, investigate sources, and arrange for examination of contacts, under the immediate supervision of the attending physician, should increase physicians' practices, assure the infected person of receiving sufficient treatment to arrest the ravages of the disease, and from a public health point of view reduce to a minimum the foci of infection and the number of diseased persons becoming state charges

Formerly when a physician suspected a person to be afflicted with gonorrhea he was required to submit an appropriate specimen to an approved laboratory for examination. This regulation has now been withdrawn because it caused unnecessary work on the part of physicians who make their own microscopical examinations, but gonorrhea is still classified

with the reportable diseases and special form SH 12 should be used for this purpose

A number of these changes have been made with the thought of making the routine work less onerous to the physician, and also of assuring the physician and patient that the identity of the patient is absolutely confidential, with the hope of securing the simplified reports for every case under a physician's supervision. If universal reporting could be achieved, it would be possible to keep the medical profession informed at all times regarding the prevalence and trend of these diseases

ALBERT PFEIFFER,

Director Division of Social Hygiene,
New York State Department of Health

THE GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Fifth Graduate Fortnight of the New York Academy of Medicine will be conducted from October 17th to 28th, 1932. The four previous fortnights have been highly popular and successful and have been graduate courses of instruction in their particular fields. The subjects have been as follows:

- 1928 Old Age
- 1929 Functional and Nervous Problems
- 1930 Acute Bacterial Infections
- 1931 Disorders of the Circulation

The subject this year will be "Tumors," and the instruction will cover all phases of the subject.

The daily program will include four features:

1 Morning clinics in six hospitals. These clinics will be free and no ticket of admission will be required.

2 Afternoon clinics in nineteen hospitals. Tickets to these clinics will be required simply because experience has shown that otherwise the rooms would be over-crowded.

3 Evening lectures in the building of the Academy of Medicine, at 2 East 103rd Street, New York City. These lectures will be given in the large amphitheatre and will be free to physicians.

4 A scientific exhibit of anatomy, pathology, research, radiology, biopsy, statistics, and books. This exhibit will be open every day and evening throughout the fortnight, and admission will be free.

Programs and invitations have been sent to every doctor in Greater New York and vicinity. Up State doctors will be made welcome. Any doctor may obtain information and tickets by writing to the New York Academy of Medicine.

THE DAILY PRESS

Mr. and Mrs.—

Just a Simple Sandwich

From New York Herald Tribune, August 15, 1932

TEA ROOM DIET

EUGENICS AND GENETICS

The meetings of the Third International Congress of Eugenics, held in the American Museum of Natural History, New York, August 21-23, 1932, elicited newspaper comments on the rivalry between that organization and that of the Genetics, which held its Sixth International Congress in Ithaca immediately after that on Eugenics had adjourned. The *New York Times* of August 24, said editorially:

"In a single week we are thus granted the opportunity of comparing the theories and methods of two schools. On the one hand, much loose talk about sterilizing the feeble-minded and restricting marriages of undesirables; on the other earnest experiments in shuffling genes, the ill-understood atoms of life, to learn how idiocy and genius may arise in the same family."

It is unfortunate that the objects of the two organizations should be confused. The Eugenicians deal with human beings—the Geneticists, with plants and animals; but the two organizations have an overlapping membership. The writer in the *Times* concludes his editorial with the remark:

"Although it is not likely that the highly technical addresses on breeding plants, mice and fruit-flies to be read at Ithaca will provide as much popular material as, for example, Professor Osborn's argument on the curbing of birth control and the encouraging of birth selection, they will indicate clearly enough that eugenics can become a practical creed only when the geneticist has discovered how the defective genes in all of us can be identified."

SPECIALISTS AS SEEN BY LAYMEN

Lay opinion of specialists is shown in the following editorial from the *New York Sun* of September 8:

"One exhaustive survey does not establish a fact, any more than one swallow makes a summer, but it is nevertheless encouraging to learn from the Committee on the Costs of Medical Care that data gathered by Dr. H. G. Weiskotten, dean of the Syracuse University College of Medicine, indicate that the tendency of medical school graduates to seek to become specialists has reached its zenith. As a matter of fact, Dr. Weiskotten's figures show merely that no greater proportion of the graduates of sixty-nine medical schools in 1925 limited their practice to a specialty than did the graduates of the same colleges in 1920. But because the tendency

up to 1920 was altogether in the direction of an increasing concentration on specialization, Dr. Weiskotten believes that in the future fewer medical school graduates will deliberately plan to become specialists.

"This is encouraging to laymen, not because they distrust the specialist but because they trust the general practitioner. Physicians themselves would be the first to admit that division of labor in the field of medicine has been carried too far in the United States. The family doctor of old often had incomplete knowledge, but his wisdom was unsurpassed; the family doctor of today is not so common and familiar a figure, not so picturesque or eccentric, perhaps, but his knowledge is greater and his experience as enriching. It is good to learn that the breed is not dying out."

BOOK REVIEWS

MIDWIVES, CHIROPODISTS, AND OPTOMETRISTS. Their Place in Medical Care. By LOUIS S. REED, Ph.D. Octavo of 70 pages. Chicago, The University of Chicago Press [c. 1932]. Paper, \$1.00. (Publications of the Committee on the Costs of Medical Care: No. 15.)

This is a small pamphlet of three major sections; one dealing with midwifery, one with chiropody and the other with optometry. Each section first presents a poorly established and largely inferential statistical statement of importance of the respective fraternities. Each section then proceeds with a more or less stereotyped formula dealing with history and the isolated activities and variously expressed opinions on the justification of the incidence of these neo-medical services. One finds many bits of interesting information but a lack of a scholarly orientation of the civics and economics of these things.

It is interesting to note that in the section on midwives, the author, in comparing the mortality record of physicians with that of midwives, quotes a certain oft-named public health doctor (who has never practised medicine) as follows: "... From some personal familiarity with the situation in Philadelphia, New Jersey and New York I think we must recognize that there is sufficiently valid evidence that the trained midwife has a superior record in cases appropriate for her care than the cases trusted to physicians exclusively."

"... (The experience) in Philadelphia, of Pennsylvania as a whole under its admirable system of state supervision, the experience of New York City over perhaps the longest period of supervision of midwives, and that of New Jersey has convinced all people in the field of public health that if they are concerned with reducing maternal and neo-natal mortality, the midwife is the answer..."

The section on chiropody deals with an explanation of its organization into a fraternity, of its schools and the legal status. As we read the last of the author's conclusions we wonder how long it will be before a committee will be knocking at the legislative chamber demanding the right to practice medicine.

The chapter on optometry follows the usual formula and brings out the interesting fact that in at least one state there has been an effort to restrict the legally qualified physicians from attempting to refract or otherwise treat disorders of vision until certified by the Optometry Board. The general tone of this chapter is not unfriendly to that point of view.

The general summary of the pamphlet is an attack upon the present individualized practice of medicine and unqualified condemnation of the present status of medical practice.

Surveys made in the medical field by people who do not practice medicine are commonly incompetent in the fundamental of the point of view. This is no exception to that generalization. F. E. ELLIOTT.

SURGICAL ERRORS AND SAFEGUARDS. By MAX THOREK, M.D. Quarto of 696 pages, illustrated. Philadelphia, J. B. Lippincott Company (c.1932). Cloth, \$10.00.

This treatise is the product of an active surgeon and teacher based upon over twenty-five years of experience. The pedagogic ability of the author is manifested in page after page of the contents. The value of the text is thereby enhanced for the reader.

These errors and safeguards are considered first in connection with surgical procedures in general. There

then follows chapter by chapter similar considerations in operations on the various regions of the body.

Every page is replete with meaty suggestions. Methods of correcting accidents at operations and after operations and the dangers to be avoided are stressed. There is appended to every chapter a very adequate bibliography.

Both the novitiate and the master surgeon can benefit much from the reading of this text.

ROBERT F. BARBER.

INTERNATIONAL STUDIES on the Relation Between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease, conducted for the Milbank Memorial Fund. By SIR ARTHUR NEWSHOLME, K.C.B., M.D. Volume 3. Octavo of 558 pages. Baltimore, The Williams & Wilkins Company (c.1931). Cloth, \$5.00.

The third volume of Sir Arthur Newsholme's studies on the relation between the private and official practice of medicine is largely devoted to England, Scotland and Wales are well studied, and Ireland incompletely. An immense amount of valuable information has been collected and made available to those interested in Community health.

Although the work is essentially a Survey, here and there Sir Arthur finds room for his own opinion. Apparently he thinks that Great Britain closely approaches adequate treatment of the problem. More time might well have been given to discussion of the income and living conditions of the average doctor. The practicing physician deserves more attention than he has received. His importance in any plan of operation is evident.

CHARLES A. GORDON.

KORYZA: der Schnupfen und seine Bekämpfung. By HERMANN ERNST. 16mo of 104 pages, illustrated. (Wien, Druck der Vernay A.-G., 1931.)

This is a curious pamphlet, published by the author in his own printing establishment, in which he describes what appears to be a purely mechanical method of curing coryza by cleaning out the pharynx, posterior nares and tonsils by means of his own tongue. He goes into the anatomy of the parts and describes the method by means of which he inserts his tongue back of the uvula. His motive for offering the work to the medical and lay public, of which latter he is a member, is found in the preface. Here he states that, as a young man, having suffered the tortures of the condemned from coryza for many years, he desires to impart to others how by accident he discovered the successful cure described in his pamphlet. It is difficult to understand just how he manages the technic of his treatment; but to the curious, the work may appeal and may lead to added knowledge of a practical nature. J. M. V. C.

A CHILD'S BOOK OF THE TEETH. By HARRISON WADER FERGUSON, D.D.S. Second edition revised. 12mo of 106 pages, illustrated. Yonkers-on-Hudson, N. Y. World Book Co. (c.1932). Cloth, 68c.

This book, designed to give good advice in an amusing manner fulfills its purpose well.

The verbal advice without the very well done pictures would have but a tithe of its value with this reinforcement; although the parents will do the reading one can cheerfully recommend this small book.

WALTER D. LUDLUM.

APPLIED PHARMACOLOGY By A J CLARK, M.C., M.D
Fourth edition Octavo of 590 pages, illustrated
Philadelphia, P Blakiston's Son & Co, Inc, 1932
Cloth, \$4 00

This fourth edition of this work on pharmacology and therapeutics proves the value of the volume. So little time is devoted to the study of drugs and their actions in the curricula of medical colleges that an accurate presentation such as this work is of estimable value. In presenting the subject the author has written of a few specific drugs and their action. He gives clearly the action of drugs upon the central nervous system, then the pharmacology of the various other systems in the body. The physiological actions are accurately presented and the therapeutic results of medication. In this volume are included a study of the action of the endocrine glands and of the importance of the vitamins. This publication is a most valuable addition to the literature of drugs and therapeutics. The subject matter is clearly expressed, logical, accurate, and instructive. From the publishers' viewpoint the presentation is excellent, large, clear type, good illustrations and upon the best paper. This work is up to date and is valuable for reference and information.

HENRY M MOSES

A TEXT-BOOK OF X RAY THERAPEUTICS By ROBERT KNOX, M.D., C.M. Fourth edition completed and edited by WALTER M LEVITT. Quarto of 250 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$7 00. (The Edinburgh Medical Series.)

This book is a revision of former editions by Dr Knox and also includes several chapters from the pen of Dr Levitt who completed the work after Dr Knox's death. The entire work appeals to the reviewer as a most satisfactory and intelligent treatment of the subject, presented in a clear and concise manner in such a way that it is understandable by the roentgen physician as well as by the trained physicist. It is rather odd that the chapters which appeal to the reviewer in particular are those contributed by Dr Levitt. Chapter two dealing with the physiological action of the x-ray together with the measurements of irradiation are excellent and is about the most complete which exists. It was a happy idea to limit the description of apparatus to the outfits which are now useful rather than following the usual course of presenting a full historical resumé of the development of roentgen equipment. Chapter eight, also by Dr Levitt, dealing with the particulars of technique, considering the physical and biological aspects with a discussion on "dosage" is most commendable. Various methods of dosage are given with the indications of each and the writer in dealing with controversial subjects has presented both sides of the problem without attempting to be in the least dogmatic.

The chapter dealing with the treatment of carcinoma is a delightful discussion of the relative merits of surgery vs radiology. The views presented are extremely liberal and therefore sane.

The second half of the book is devoted to the treatment procedures for various conditions. This is very complete and intelligent and the technique for the measurement of each condition is given in a lucid manner.

The entire work is most praiseworthy and probably the best work of its kind that has yet been produced. The publishers are to be congratulated upon their splendid press work and the clarity of the illustrations which are numerous and beautifully executed.

CHARLES EASTMOND

PRIMARY CARCINOMA OF THE LUNG Bronchiogenic Cancer. A Clinical and Pathological Study in Two Parts. By B M FRIED, M.D. Octavo of 247 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1932. Cloth \$5 00. (Medicine Monograph XIX.)

This is an excellent study of primary carcinoma in the lung, in which the author deduces the fact that he is not dealing with a new, unusual and increasing condition, but with one recognized more frequently because of better methods of diagnosis, and because of better instruction and information concerning the condition. The author is led to believe by his studies that the usual pathologic classification is erroneous and that all primary carcinoma of the lungs are bronchiogenic in origin. This belief will no doubt lead to some discussion. The incidence, etiology, histogenesis, the classification, the metastasis together with the methods of diagnosis are all carefully presented. Many cases are reported in detail illustrating the various manifestations of this disease. For anyone interested in malignancy in the lung or else where this volume presents every aspect of the subject. The publishers have given us an excellent volume with many illustrations clearly and accurately presented.

HENRY MONROE MOSES

THE RHEUMATIC INFECTION IN CHILDHOOD By LEONARD FINDLAY, M.D., D.Sc. Octavo of 187 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$3 50.

This monograph is based on the study of 693 cases of rheumatic infection in childhood, which the author has observed at the Royal Hospital for sick children in Glasgow between the years 1914 and 1930.

It is an interesting and important study not only because there is so much to learn about this disease but also because of the remarkably long period of follow up, averaging five years, during which the observation of the patients has been carried out.

The Author's presentation is largely clinical in nature and is accompanied by a number of statistical tables and graphs, upon which he justly bases his conclusions which he freely expresses relative to many points in etiology and symptomatology.

The chapter on treatment confirms the value of salicylates if used in sufficiently high dosage. The author is not optimistic about the cure of this condition once the heart has been involved and believes that our goal lies in prophylaxis, drawing the very important conclusion thereof that it is the poorer classes who live under unsanitary conditions of housing who suffer most and that therefore the keystone of prophylaxis should be the provision of healthy houses for this class of the community by housing reform.

JOSEPH C REGAN

PATHOLOGY FOR NURSES By EUGENE C PIETTE, M.D. Octavo of 251 pages illustrated. Philadelphia, F A Davis Company, 1932. Cloth, \$1 75.

Nurses completing their crowded medical curriculum frequently enter their duties viewing medicine as a crossword puzzle which gradually will untangle itself into concrete facts. The reviewer's experience in teaching nurses has caused him to appreciate their need for a text book on the nature of disease so as to provide them with a ready source of reference. This book fulfills this requirement. It teaches the nurse enough pathology to make her a better practical nurse in the handling of specimens and in understanding the patient's needs. In brief, it gives the nurse a better perspective of disease.

S H POLAYES

OUR NEIGHBORS

THE JOURNAL OF KANSAS

The August issue of the *Journal of the Kansas Medical Society* contains the annual reports of the officers. The financial report of the Journal may be summarized as follows:

Receipts

Journal advertising	\$1,239.66
Sales and subscriptions.....	312.56
Kansas Medical Society.....	2,000.00
Other sources	12.48
	<hr/>
	\$6,564.70

Expenditures

Journal printing	\$2,539.25
Stock and stationery.....	833.55
Salaries and wages.....	2,364.00
Postage	153.77
Electrotypes	78.40
Office rent	225.00
Drayage	7.75
Telephone	62.93
Insurance	9.74
A.M.A. directory	12.00
Office equipment and supplies.....	50.82
	<hr/>
	\$6,337.21

Salary due Dr. Brown.....	500.00
Salary due Miss Carlson.....	90.00
Deficit May 1, 1931.....	218.83
	<hr/>

Total deficit May 1, 1932.....	\$ 581.34
Bills payable	61.50
	<hr/>
	\$7.207.54

Commenting on the report, the editor says:

"The amount of our advertising receipts, sales and subscriptions and other sources, is \$190.74 less than in 1931. This is due to the difficulty we are having in retaining our old advertisers and in securing new accounts. Several large manufacturers, sanitariums and hospitals have discontinued their advertising temporarily. However, we are encouraged at the present time because new accounts have been received. The General Baking Company are using a one-half page advertisement; The National Drug Company have ordered a page advertisement, every other month, beginning with the May number; the S.M.A. Corporation have increased their advertisement from a quarter-page to a half-page, and E. R. Squibb and Sons are continuing their advertisement of one page a month, preferred space. This is interesting due to the fact that they had ordered us to change their advertisement to one page every other month for the year 1932.

"The Journal printing, stock and stationery are less. We have a new contract with our printer, obtained in March, 1932, which will reduce this item very much, if we can keep our mailing list up to standard and near the 1800 mark.

"Our salary item is more because it was imperative that we have more help in the office. Our postage and electrotypes are considerably less than in 1931. Our rent is \$75.00 less due to the fact that we crowded the Bureau and Journal equipment into one room last fall to reduce expenses as much as possible.

EX-PRESIDENTS IN NEBRASKA

To find a place for honorable service for ex-presidents of the Medical Societies of some States seems to be a problem which the New York State Society does not have to meet, as was shown in an editorial on page 1024 of this Journal of September first. Concerning the continued service of the ex-presidents of the Nebraska State Medical Association, the *Nebraska State Medical Journal* for September says:

"Under the By-Laws of the Nebraska State Medical Association a past president becomes a member of the house of delegates for life on the

theory that the special knowledge gained while president should make the individual a valuable member of the councils of the house of delegates and also by a later enactment the recent past president is a member of the Council for one year immediately succeeding his term as president.

"At this time there are living twenty-four former presidents of the Nebraska State Medical Association, twenty-one of whom live within this state. The roll call of the house of dele-

NEW!

A NEW NON-STAINING GENITO-URINARY ANTISEPTIC

AMBAZIN

Diphenyl disazo-ethoxyaminophenol aminobenzoic Sodium plus Hydroxyquoline sulfate

For oral administration in infections of the upper and lower genito-urinary tract.

Note these EIGHT cardinal advantages:

1. *Non-Staining.*
2. *Excreted the natural color of urine.*
3. *High bactericidal and bacteriostatic action.*
4. *Nontoxic, non-irritating to urinary tract.*
5. *Well tolerated by the gastro-intestinal tract.*
6. *Unusually low incidence of secondary complications with tendency to shorten the course of treatment.*
7. *Prompt elimination.*
8. *Economical price to patient.*

Affords a valuable adjunct to local treatment in infections of the urinary tract.

ADMINISTRATION—One capsule three times daily, limiting the fluid intake to 1500 c.c. in twenty four hours so as to provide sufficient concentration within the maximum therapeutic range of the drug.

Let us send you a full size package of AMBAZIN together with a reprint of the published work.

gates reveals a lamentable lack of apparent interest of most past presidents in medical organization. At the annual session of the past five years but three past presidents consistently attended all the meetings of the house of delegates, took an interest in all the proceedings and participated in the discussions. In 1928, six attended one or two meetings; in 1929, seven; in 1930, eight; in 1931, seven; in 1932, nine. In most instances, of those who attended but one or two roll calls, the interest may be said to have been perfunctory.

"On a previous occasion we stated that no physician is so proud of position in life and of his attainments as to despise the honor of the presidency of the State Medical Association. The honor of the presidency can come to but a few men. A man is picked for the presidency, because he is an outstanding man in scientific attainments, or because his activities in medical organization have seemed to fit him for the place.

"These men owe something to the organization that has so signally honored them. Can it be that all they care for is the honor, and after that has been bestowed they are content to rest on their laurels and let the organization drift whither it may?

"Certain it is that a lamentable lack of in-

terest is evidenced by many former presidents in a work that should call forth their best efforts during their active years."

The NEW YORK STATE JOURNAL OF MEDICINE for May 1, 1928, page 552, printed an abstract showing how well the ex-presidents of the South Carolina Medical Association continue their interest in organized medicine.

WOMAN'S AUXILIARY IN ARKANSAS

The leading article in the August number of the Journal of the Arkansas Medical Society is the address of Dr. D. A. Rhinehard, President of the Society, at the Annual Meeting of the Woman's Auxiliary, in which he describes the perfect wife of a practising physician as follows:

"You can encourage your husband in attending the meetings of the different medical societies to which he belongs because he will learn something at the society meeting and he will become friends with the other physicians in the community in which you live. The quality of medical service is better in those that have active medical societies than in those that do not.

"You can be of help to your husband in

*Definite dosage
Ease of administration
Sensible economy*

Each pill contains 0.1 gram (1½ grains) of physiologically tested digitalis leaves. The finished pills, too, are biologically assayed, thus giving re-assurance of their activity.

Each pill represents 15 minims of the U.S.P. tincture and permits of more accurate dosage than do liquids, as drops may vary in size.

These pills contain digitalis in its completeness and not any separated or extracted part of it, therefore present the entire therapy of this valuable drug.

Physician's trial size package and literature sent free upon request.

getting the correct mental slant on his competitors. You can adroitly help him put the most kindly interpretation on events and occurrences of which he has heard; you can remind him that the layman's ideas about medical affairs are apt to be quite nebulous and more often incorrect than correct.

"One of the gravest mistakes that you can make in your Auxiliary work is to permit your opinion of some doctor's wife to be influenced by what your husband may think of her's. You should carefully guard against such, and base your opinions entirely on the true worth of the other woman as an individual. Should you find her worthy, your friendship with her may be a means of ending the antipathies your husbands have for each other.

"You can also help liberalize your husband's ideas on a great many subjects, for instance, take such a simple thing as the examination of children of pre-school age for the presence of remedial physical defects.

"Again, consider the matter of public health instruction, whether in the schools or elsewhere. The object of such instruction is to teach people how to keep themselves well. It would be more pleasant to deal with well patients than it would with sick ones. You, therefore, not restrained by the old conventions that affect your husband, may help by showing him wherein something that will happen in the future will more than offset something to which he objects in the present.

"Perhaps the most important function of all that you may perform for your husbands is to represent them and the medical profession at times and places where they cannot be present themselves.

"It may be assumed that the physicians themselves are amply able to counteract that part of this unfavorable notice they meet, but in the course of the day's activities, it is quite probable that physicians' wives have more occasions than they. To deliver the report courteous so that it may be effective, you must be informed on these subjects. This information you will obtain from "Hygeia," from the "Propaganda for Reform" department of the *Journal of the American Medical Association*, from the *Bulletin of the American Medical Association*, and from the various special publications of the Association. These latter can either be obtained gratis or for a very nominal sum.

"Having become informed, it is then necessary for you to make associations such that you will be able to disseminate this information. As set forth in the purposes of the

THE SECRET OF EFFECTIVE SALICYLATE MEDICATION

MASSIVE DOSAGE AND THOROUGH ALKALINIZATION

- Every physician realizes the importance of pushing the dosage of salicylates at the outset of treatment, in order to effect the desired rapid salicylization of the patient.
- The difficulty has been to give adequate dosage without at the same time setting up objectionable side effects. This difficulty has now been overcome with the introduction of

ALYCIN

- Alycin combines in one formula Merrell's Natural Salicylates with a balanced alkali. Long years of clinical experience show that Merrell's Natural Salicylates can be given in large doses without gastric disturbance. The concomitant use of an alkali—the modern method of administering salicylates— aids toward a more rapid absorption, quicker effect, and helps to safeguard against cardiac dilation and the frequent accompaniment of rheumatism and febrile conditions—acidosis.
- Special attention is directed to the balanced alkali formula which permits large dosage without disturbing the mineral balance, or producing alkalosis.
- Let us send you a bottle of Alycin and complete information so that you can make a thorough clinical test of this modern form of salicylate medication.

ACTIVITIES OF THE NEW HAMPSHIRE MEDICAL SOCIETY

The New Hampshire Medical Society does not publish its own Journal, but utilizes the first issue of each month of the *New England Journal of Medicine*, and purchases a sufficient number of that issue to supply each of its 476 members. The August fourth issue of the Journal contains an account of the annual meeting of the New Hampshire Society, held in Manchester on May seventeenth, when the Presidential address was given by Dr. G. C. Wilkins. In closing, Dr. Wilkins discussed society expenses and dues as follows:

"The financial condition of the society is good, but in order to keep pace with the increasing duties devolving upon the society and its officers, it was found necessary to increase the dues. Even at this present figure one finds that only twelve states have dues as low as ours. (Four dollars. Four Southern States have dues of only three dollars.—Editor's note.) If, and when, the financial depression lifts, we must look forward to a further increase in dues if we wish to carry on effectively. Added expenses have come on account of our participation in the deliberations of the New England Medical Council, the development of the work of the Committee on Jurisprudence, and the distribution of one monthly copy of the *New England Journal of Medicine*. We should gradually increase the salary of the secretary as his duties increase and he should at once receive an increased amount of clerical help. An increase in the activities of our society and its subjective committees automatically increases incidental expenses. If our desire is to keep abreast of contemporary societies, we will need to expend more money, and collect higher dues."

Concerning the New England Medical Council, Dr. Wilkins says:

"The importance and significance of the results of cooperation among the six New England medical societies cannot be estimated by a mere perusal of the minutes of the meetings. The meetings have offered an opportunity for discussions on many subjects of vital importance, by men from widely separated sections of New England. Progressive and constructive legislation has frequently been adopted by the various State societies as a result of policies and ideas developed in the deliberations of the New Eng-

land Medical Council. I am sure our enthusiastic support of the New England Medical Council will continue."

Dr. Wilkins discusses the scope of work of the Advisory Committee on Jurisprudence, as follows:

"This committee has continued its excellent work during the past year, and should receive whole-hearted support from the physicians of the State. Dissatisfaction on the part of patients can be reduced in three ways: first, by refraining from any remark that may be construed by the patient as criticizing the method of treatment of another physician; secondly, by insisting on adequate x-ray examination of all fractures; and thirdly, by not attempting, except in emergency, treatment with which one is not familiar. Always bear in mind the words of Lincoln, spoken by him in a law lecture before he became president, 'Never stir up litigation. A worse man can scarcely be found than one who does this.' Remember that an increasing number of suits are shown in rising insurance premiums. The rise in insurance premiums will be further emphasized if some of our members continue in their attitude of unwillingness toward joining the

larger group, representing the State Society, in cooperation with one insuring body."

MEDICO-POLITICAL PROBLEMS IN TEXAS

The leading editorial in the July issue of the *Texas State Journal of Medicine* discusses the medico-political problems of the State Medical Association of Texas. The editor touches on several debatable subjects including prohibition, the Sheppard-Towner bill, veterans' relief, and antivivisection. Concerning the liquor problem, the editor says:

"The liquor problem is the one which appeals to most thinking people, and physicians, being men of decision and of action, are emphatically pro or anti. We look upon the problem from a dual viewpoint. Alcoholic liquors are with us as they are with other people, a moral issue, and at the same time they constitute a problem in the practice of medicine. Therefore, we are doubly burdened with this particular responsibility: At the same time, there are multiplied thousands with equally as emphatic views if not actuated by the same reasoning; and where we must decide as be-

tween our partisan views on liquor and our obligations to the public health, there can be no question as to our duty. We are hoping that our readers will be a unit in voting for the best interests of medicine and the public health.

"The medical liquor question is continuously a thorn in the side of the medical profession. The American Medical Association insists that the physician be either denied the privilege of prescribing liquor or be permitted to prescribe it in such amounts and at such times as it may accomplish the intended purpose.

"Our congressmen should not be in favor of the formerly so-called Sheppard-Towner Bill and at the present time, we believe, designated as the Maternity, Child Welfare and Rural Health Bill. This measure, in effect, comprises a federal subsidy for the control of state health activities. It is extremely objectionable from several angles, perhaps the most important of which is that it is a step towards the socialization of medicine.

It is the view of the medical profession that the prolific erection of hospitals throughout the country for the care of veterans can have but one end, and that is the establishment of a great organization eventually to be devoted strictly to socialized medicine. In the meantime, it is our view that the government must have a certain number of hospitals in which to care for specialized illnesses, such as tuberculosis and nervous and mental diseases, and such service-connected disabilities as require the compiling of large files and the winding of much red tape. It is our thought that the veteran himself can be best served by caring for the non-service disability cases and the emergency cases, at least such of them as the government desires to assume responsibility for, at home, by home hospitals and by home physicians.

"The ethical medical profession of Texas insists upon it that the present fair, reasonably high and rather practical medical standards be maintained; that no special legislation authorizing the practice of medicine or any part of it, by cults, be enacted. Of equal importance is the necessity of approaching public health understandingly and doing something about it. Among these is the need of revamping our present sanitary code, which is in many respects obsolete. It is possible that the antivivisectionists will reach Texas soon in their general campaign to outlaw animal experimentation, and several movements are on foot looking to the eventual socialization of medicine, any one of which may be heard from at any time.

"Those candidates for the legislature for whom we vote should be willing to counsel with us in regard to these and related matters, whether or not they agree with us, and, of course, those who agree with us should be favored above those who do not, granted moral and personal competence."

S·M·A·CORPORATION

of Cleveland, Ohio, announces to the medical profession that it has been awarded sole rights for the ethical distribution of

VITAMIN D

produced from Cod Liver Oil
under license United States patent 1,678,454
issued July 24, 1928, developed in the laboratories of and controlled by Columbia University.

This is Natural Vitamin D, not an irradiated product, and not a cod liver oil concentrate, but rather a highly potent extract of the antirachitic principle of cod liver oil. It is extracted and prepared in suitable form for therapeutic use by methods developed by Doctor Theodore F. Zucker, Assistant Professor of Pathology at the College of Physicians and Surgeons of Columbia University.

This Vitamin D is now available for therapeutic use in 5cc and 50cc bottles. The concentration is such that 10 drops is equal in Vitamin D potency to three teaspoons of standard potent Cod Liver Oil. It is palatable and free from objectionable taste. This new product will be ethically advertised and carefully distributed through prescription pharmacies. It will be sold at prices approximately the same as those current for equivalent dosages of plain Cod Liver Oil. Interested physicians are invited to write for full information and complimentary samples to S. M. A. Corporation, 4614 Prospect Ave., Cleveland, O.

GRADUATE COURSES IN VIRGINIA

The July issue of the *Virginia Medical Monthly* contains the following comments on the clinical instruction sponsored by the Medical Society of Virginia:

"With three of the ten meetings in the first series of post-graduate courses in prenatal and postnatal care completed, the enrollment of physicians has reached a total of seventy-five.

"Almost without exception physicians approve the general plan of post-graduate educational opportunities, but the supreme test comes when the actual presentation of a specific subject must measure up to their needs and demands. Unsolicited notes of appreciation, repeating the terms "interesting and enjoyable," "practical," "valuable," "profitable," show that this program bids fair to fulfill in marked degree the purposes for which it was established.

"In two other respects a favorable start can be reported. Through the cooperation of members of the groups, clinical material, upon which much of the effectiveness of the course depends, has been made available in every case except one. Furthermore, Dr. Lapham, the Field Clinician, is receiving an increasing number of requests for examination of patients at the offices of physicians in his classes. Dr. Lapham sees no patients with-

out the recommendation of a physician and communicates with them only through the physician. His out-of-class hours will be devoted to such consultations for educational purposes without cost.

"In the case of the present program there is probably a premium upon early organization. The expenses for the first year are entirely cared for by the appropriation of \$2,500 made by the Medical Society of Virginia at Roanoke and the grant of \$10,000 from the Commonwealth Fund. The Joint Committee felt it was advisable to establish at the beginning of the courses the principle of partial self-support by the students themselves, and for that reason it has set an enrollment fee of \$5.00 per student for the course during the first year. For the proposed second and third years required to place this educational opportunity in every section of the state where it is desired, the grant of the Commonwealth Fund is tentative and reduced in amount. If an increase in the enrollment fee should become necessary, only the students during the first year will have the advantages of the minimum rate. Officers and members of societies in consideration of this fact are urged to begin arrangements for offering the course to their colleagues as promptly as possible."

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min.
GUAIACOL	1 min.
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve Bronchitis—acute or chronic. It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

GENERAL BAKING COMPANY
Department of Nutrition, L-23
420 Lexington Avenue
New York, N. Y.

Dear Sirs:

Kindly send me a copy of your Comparative Nutritional Chart

(Continued from page 1159—adv. xxv)

Budget your Council effected the following economies in similar services of a year ago: Rent, \$240; Press Service, \$550; Editorial Board, \$1,000 and Secretaries' Conference, \$500. It appears that current income of the year will be sufficient to balance this budget and to meet any incidental items that may arise in the next six months. It does not appear that the income will be more than sufficient.

"At your session ten years ago it was your decision to increase your dues from \$4 to \$9 to permit the employment of a full-time lay Secretary-Managing Editor. At that time your Secretary had no reserves and was, in fact, meeting No-

vember bills from the next January receipts. In an organization charges with such duties and whose work was of such importance to the economic stability of the profession, it was thought fitting that the Society should have a reasonable surplus. Through the ten-year period this surplus has reached the sum of \$25,000, something less than the budget of the Society for a single year. This surplus of \$25,000 is comparable to those of \$110,000 in Illinois; \$50,000 in Michigan; \$32,000 in Iowa; \$25,000 in Minnesota and \$30,000 in Indiana.

"The annual cash income of the profession of this state is estimated to be in the neighborhood of nineteen millions of dollars. Our annual budget to do all of the work of the Society including that to protect our membership against impositions and injustice is but \$28,000. So long as this income is used wisely and the activities of your Society are carried on efficiently, certainly it would not appear that our budget of one and one-half one thousandth of our income is excessive. On the contrary it seems to be a very small amount."

WOMAN'S AUXILIARY IN PENNSYLVANIA A CENTURY AGO

Mrs. David B. Ludwig, Pittsburgh, Historian of the Woman's Auxiliary of the Medical Society of the State of Pennsylvania, writing in the *August Pennsylvania Medical Journal*, comments on what an Auxiliary Convention would have been one hundred years ago, and said:

"Oh, it would have been an interesting time—that convention of 1832. And if the Auxiliary had come what would it have done? We wonder, for budgets had never been thought about; by-laws were a thing of the far-distant future; there was no need of councilors, and *Hygeia* could not have been sold. Legislation was something which concerned only the dominant male; and as for nominations and periodic health examinations, programs and health education, there was no time for them and they could not have had Public Relations and Publicity, because there wasn't much *public*, and the *relations* consisted of a couple of grandmothers, several maiden aunts, and a Beau Brummel bachelor uncle. The yearbook was the family Bible, and the program of the auxiliary a hundred years ago was the daily care of a husband who had dedicated his life to the art of medicine and the bearing and rearing of sons and daughters to carry on the race, better because she lived.

"There were no impure streams to purify; there were no reports to be read. What an uninteresting time the auxiliary a hundred years ago would have had! But then they possibly would not have come. It was October—they would have stayed home and made apple butter and pickled sickle pears."

**COMMITTEE
ON PUBLICATION . .**

MEDICAL LIBRARY IN KANSAS

The July issue of the Journal of the Kansas Medical Society contains the following report on the Stormont Medical Library which seems to be under the direction of the State Society:

"The Stormont Medical Library is composed of approximately 2,400 accessions, chiefly in the form of books and reports.

"This library is housed in the state library in the state house at Topeka and cared for by the librarians in that library. It is supported by the interest from a sum of money, approximately \$5,000 invested by the state treasurer and bringing in revenue approximating \$300 each year which is spent on new books and on magazine subscriptions. The cost of binding the magazines is stood by the state and there is no charge on the part of the library for indexing the books.

"At the report of this committee last year it was suggested that men over the state be permitted to write in to the library, request a particular journal or book and receive it loaned for a period of two weeks providing they were members of the society to use the library. The suggestion, however, has not been followed, and not a single request has been received all year, and there are very few men who make use of the library.

"At the present time the fund for purchasing books amounts to only \$23.00 and no books have been bought this year. The reasons for this sum in the treasury are accounted for because prior to appointing of a state Library Committee no one had direct charge of the library and the librarians were accustomed to ordering things almost any physician suggested, with the results that there was considerable money promised on periodicals, systems of medicine and the like when this committee took charge, and it was necessary to stop several of

these general subscriptions as well as pay up the bills owed before we attempted to order any books."

MEDICAL PUBLICITY IN SOUTH CAROLINA

The presidential report of Dr. C. A. Mobley to the House of Delegates of the South Carolina Medical Association, printed in the June issue of the State Journal, suggests the following plans for medical publicity to be conducted by the State Association through bulletins and the newspapers:

"I have two minor matters that I wish to bring up that I think would be of a constructive nature, and I should like them to be considered, though not necessarily acted upon to night, by any means. I think it would be well to have a monthly bulletin mailed by the secretary of the State Association to each of the county medical societies, and also to the district societies, in which he can set forth any points of interest brought out in our state journal, or in the Journal of the American Medical Association, or any point that he comes across in his reading of other journals, or any matter of interest to the medical profession. He could make a mimeographed bulletin and mail one to each of the county medical societies and also to the district societies. I think that this would have a tendency to make our whole state association more cohesive. They would feel each month that the state society was having an interest in them.

"There is another thing which I believe should be done, and I think some time in the near future is the time to start it. I believe that the South Carolina Medical Association should publish informative and educational articles on health, disease, and things medical in the public press, in the newspapers. I think that they should not be signed by any one man, but that they should be published under the auspices of the South Carolina Medical Association."

WHITE PLAINS, N. Y.

FOR SALE—Nice house, with physician's office, in very center of the city. The practice is 25 years' duration. Exceedingly suitable for young married doctor or dentist, in a growing town. Address Box 33, Care of N. Y. State Journal of Medicine.

WANTED—Physician desires a position in Sanitarium specializing in mental disorders. Experienced. Good personality. Cooperative. First class reference. Address Competent, Box 34, care N. Y. State Journal of Medicine.

PATHOLOGIST—B.S., M.D., D.P.H., desires affiliation with institution or clinic group. Excellently trained here and abroad. Seven years in Clinical Pathology and all branches. Teaching experience. A-1 references. Address, Box 35, care N. Y. State Journal of Medicine.

MOVIE HEADQUARTERS—16 and 9½ mm. Exceptional values in NEW AND GUARANTEED USED Cameras, Projectors. Film and accessories. BELL-HOWELL, PATHE, EASTMAN, AGFA and other standard equipment at special prices. 400' Reels, 38c; Humidors, 45c; Cement, 20c. 100' Reversible Film (including processing), \$3. 100' ART Film, \$3. Large Rental Library—membership FREE! Film and Bargain List upon request. Mogull Brothers, 1944-A Boston Road, New York City.

AMERICAN COLLEGE OF SURGEONS

The New York and Brooklyn Regional Fracture Committee of the American College of Surgeons will give its annual course on fracture treatment from October 31 to November 5, inclusive.

This course is given by men who are interested in the care of fractures,

the clinics being held at many of the leading hospitals of New York City. The course covers a large scope and, in the past, has been attended by physicians from many of the States.

The clinical lectures to be given will be illustrated by demonstrations of actual cases and will cover the diagnosis and treatment of all types of bone injuries.

In addition to this, there will be symposiums on bone repair, the operative treatment of fractures, the use of local anesthesia in the care of fractures, delayed and non-union in fractures and the care of compound fractures.

Information concerning this course can be obtained from the secretary, Dr. Fenwick Beekman, 121 East 60th Street, New York City. See page xxviii.—Adv.

WHAT IS MALTCOA?

Maltcoa is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

"MALTCOA" ANALYSIS:

Moisture	3.03%
Cocoa Butter	4.42%
Butter Fat56%
Milk Solids not Fat	10.09%
Crude Fiber89%
Cane Sugar	45.07%
Maltose	14.72%
Total Protein	9.87%
Dextrin and Other Carbo- hydrates	7.36%
Mineral Ash	3.99%
	100.00%

COURSE OF FRACTURE TREATMENT 1932

Ten Clinic

Lecture Demonstrations

given by

The New York and Brooklyn
Regional Fracture Committee
of the
American College of Surgeons

A concentrated course embracing the practical application of modern methods of fracture treatment—from October 31 to November 5 inclusive.

Clinics will be given at the following hospitals:

Presbyterian, Harlem, Beekman, Bellevue, Roosevelt, Ruptured and Crippled, Long Island City and Cumberland Street.

Attendance is limited. \$25 is charged for the course.

For further information address

FENWICK BEEKMAN, M.D., Secretary

THE DR. C. O. SAHLER SANITARIUM

Pleasantly located in the suburbs of the charming city of Kingston. Within easy access of New York, and with all modern facilities for treatment of selected cases of Organic and Functional Disorders of the nervous system and invalidism from any cause. Average price of rooms—without bath—\$5.00 per day including ordinary medical and nursing attention. No cases of insanity or communicable diseases accepted. Booklet on request. Telephone Kingston 948. Raymond S. Crispell, M. D., Medical Director.
Kingston-on-Hudson, New York

SOME OF THE PROBLEMS ASSOCIATED WITH PEPTIC ULCER*

By E. STARR JUDD, M.D., ROCHESTER, MINN.

PEPTIC ULCER has rightfully claimed much attention, for this lesion is a threat to life.

Furthermore, its distribution among persons in all walks of life gives it great significance, when one considers the curtailing effect of it on the enjoyment and maintenance of normal activities. Through persistent study, methods of treatment have been developed, which, if properly applied, are usually successful. Yet there is a percentage of cases in which a satisfactory result is not obtained, for some unknown reason.

This problem has been approached experimentally. The following data were obtained from Mann and Bollman of the Institute of Experimental Medicine of The Mayo Clinic. Acute gastric ulcer and acute duodenal ulcer have been produced by numerous methods, but subacute and chronic ulcer rarely have been developed in animals. Multiple and single ulcerative lesions of the gastric and duodenal mucosa have been produced experimentally. The acute ulcerative type, most often secured, does not become chronic. It is usually multiple and is more often found in the mucosa of the fundus than in the mucosa of the pylorus or duodenum. This type of lesion is readily produced by injection of toxins, certain drugs, and bacteria, and it appears in some moribund conditions which follow loss of the suprarenal and parathyroid glands, as well as after section of the splanchnic nerves and other operative procedures. According to the experience of Mann and Bollman, if the animal survives the operation, healing of the ulcer always occurs, and no trace of the lesion remains. The other type of ulcer occurs more often, and under definite and limited conditions. It is usually single, and is situated in the pathway of the outflow of gastric content, never in the fundus. In the beginning the lesion is acute, but if perforation with peritonitis, or fatal hemorrhage does not occur, it quickly becomes chronic. Grossly and microscopically this lesion resembles peptic ulcer as found in man.

Whether either of these two types of lesion

corresponds exactly to the types seen in man has not been definitely determined, owing to the fact that the process of development of the lesion in the gastro-intestinal tract of man is not known. Experience teaches that these typical ulcers occur mainly in the portion of the digestive tract which is exposed to contact with an acid substance, and which appears to be subjected to the greatest mechanical trauma by passage of gastric content. For this reason, practically all of the various methods, both medical and surgical, that have been devised to treat the patient with peptic ulcer have for their main object protection of the lesions from chemical and mechanical injury. And these facts have determined the experimental approach to the problem.

In 20 per cent of animals used in experiments, chronic peptic ulcer develops just distal to the pylorus if the duodenum is removed, if the first portion of the jejunum is anastomosed to the stomach, and if the common bile and pancreatic ducts are transplanted into this loop of jejunum.

In some experiments the secretions that normally are poured into the duodenum by the glands extrinsic to the gastro-intestinal tract, that is, the liver and the pancreas, have been eliminated. The ducts from these glands have been transplanted into the terminal part of the ileum. In about 50 per cent of the animals thus operated on, peptic ulcer developed in the duodenal mucosa, at the usual site of duodenal ulcer in man.

Finally, in a large series of animals, the entire normal mechanism for receiving the acid gastric content was eliminated by functionally resecting the duodenum. The gastric content was diverted directly into the jejunum, without being mixed with the secretions which normally enter the duodenum. The secretions were all drained into the ileum. Various investigators have found that when these conditions are imposed, ulcer will develop in about 95 per cent of experimental animals.

Recently Wu, working in the Institute of Experimental Medicine, showed that the mucosa in which the experimental ulcers were produced was subjected to contact with gastric content of

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

which the hydrogen-ion concentration was on the acid side most of the time, and that, at intervals, acidity was marked.

Studies showed that maintenance of the normal reaction of the duodenal content is highly important in prevention of ulcer. The significant factors in maintaining normal reaction of the content are the duodenal mucosa and its secretion, the pancreatic juice, and the bile. Ulcer occurred much more frequently among animals in which all of these factors were eliminated than among those in which only part of them were eliminated. The significance of acid in the production of ulcer cannot be overestimated. Apparently active neutralization goes on during the course of digestion, and alkalization is more effective in reducing excess acidity during digestion than during fasting. After an ulcer has been produced, the neutralizing power of the stomach toward administration of acid seems to be markedly reduced. Administration of acid in the presence of peptic ulcer creates considerable disturbance: emesis is produced by only a few cubic centimeters of dilute hydrochloric acid. Similar observations have been made in man by Dragstedt and Palmer. Peptic ulcer, produced by administration of acid, will begin to heal in a few days after discontinuance of the acid. Short periods of administration of acid may greatly retard healing, and may produce extension of the ulcer. The mechanical factor must also be of considerable significance, since the ulcer always develops 1 to 2 cm. distal to the point of exit of the gastric content from the stomach. The site of development of the lesion is typical and constant unless the axis of the loop of the intestine is changed. The lesion usually will develop more rapidly, and will be more prone to undergo perforation if the opening at the line of the gastro-intestinal anastomosis is made small, for a small opening causes the gastric content to impinge with greater force on the area of the lesion.

The same agencies which are responsible for production of ulcer prevent its healing, and cause chronicity. Reparative processes can be demonstrated in all ulcers at any stage of their development; repair begins immediately after injury to the mucosa. Destruction and repair go on simultaneously throughout the course of development of the ulcer, except when it is completely protected from the gastric content. Only when the ever present reparative process can take place faster than the destructive process does healing occur. Healing of experimentally produced peptic ulcer takes place spontaneously if continuity of the tract, ducts, and glandular structures is restored. Treatment by diet, alkalization, medicines, and emollients has been studied in the work with experimental animals. There appears to be a somewhat quantitative relationship be-

tween ingestion of food and gastric acidity. Because of the attendant danger of alkalosis, permanent neutralization of gastric content over a period necessary for healing of ulcer is not feasible. The use of certain emollient substances gives promise of helping to solve the problem, but investigative work shows that means must be found of controlling the action of some of the ingredients before any such plan can be adopted as a routine. Harper has produced healing by the use of an emulsion which has little neutralizing ability but which apparently efficiently protects the mucosa from injury. Time is an important factor in successful healing of peptic ulcer; treatment must continuously suppress mechanical and chemical factors during the entire period of healing.

Clinical Features

Diagnosis of duodenal ulcer is usually readily made from the history, and then confirmed by roentgen examination. One of the interesting features is the seasonal nature of the complaint. It is difficult to understand why, in the spring and autumn, a patient will have all of the usual symptoms, not easily controlled by most rigid treatment, and then, within a few days, will have complete freedom from symptoms. During this period of comfort he may be very indiscreet about his living and his diet, and still not have any symptoms. Looking at this from the standpoint of the lesion itself, it certainly is not reasonable to assume that the ulcer healed during the period of remission. It also seems difficult to explain this feature of the complaint on the basis of disturbance in the nervous system.

It seems to me that in the last few years more patients with bleeding ulcer have been seen than formerly. Bleeding from these lesions is often severe, and may place the patient in a serious condition, although loss of life from such bleeding is very unusual.

Rivers and Wilbur recently have completed a study of the diagnostic significance of hematemesis. They reviewed 668 histories of cases. In 236 of the cases, operation was not performed, but the diagnosis was made after careful clinical investigation. In 432 of the 668 cases, surgical exploration was carried out. The investigators noted that duodenal ulcer alone was responsible for hemorrhage in half of the cases, and gastric ulcer was responsible for only 6.4 per cent of them. Carcinoma was the cause in less than 13 per cent. They expressed the belief that the source of the blood usually can be determined with accuracy if data obtainable through a detailed anamnesis, careful general examination, and laboratory studies are evaluated cautiously. They also stated that indigestion and hemorrhage usually mean an intrinsic gastroduodenal lesion. Duodenal lesions occur more frequently

among males than females. The incidence by age is difficult to determine, for in some cases periods of remission of symptoms help to make the history obscure, and encourage delays in seeking treatment. In other cases, rapid onset and severity of symptoms have caused the patient to seek attention early in the course of the disease. Some patients are in their teens, but the majority are in the middle years of life.

Treatment

In the presence of conflicting views regarding the origin of ulcer, different forms of treatment are justified only on the basis of experience. A sharp line must be drawn between gastric and duodenal ulcer. In the first place, in considering the problem of ulcer, it is necessary to keep in mind the high incidence of malignancy in gastric lesions and the predominantly benign nature of those which occur in the duodenum. Barring other considerations, such as hemorrhage, treatment of these conditions should be tempered accordingly. No matter how small a percentage of gastric ulcers is malignant or will become malignant, the possibility that they will become malignant at all adds to the seriousness of the disease. Radical operation is preferable for gastric ulcer if there is considerable associated gastritis.

Many duodenal ulcers heal permanently under medical treatment. Anyone with a duodenal ulcer is entitled to a trial of this type of treatment, and to continue with the regimen as long as it is helpful. It is not a good plan to operate when the lesion is bleeding. If the patient has had one hemorrhage only, and is free from symptoms at the time of the examination, it is not necessary or advisable to operate immediately. If he has recurrent symptoms, then an operation may be indicated. Should surgical treatment become necessary, particularly because of repeated, severe hemorrhage, it is imperative to remove the ulcer, if this can be done thoroughly by excision, taking part of the pyloric sphincter muscle. With this removal of muscle, everything is accomplished that can be expected of gastro-enterostomy, and the ulcer is also removed. The operation of excision was developed for use in those cases in which it was possible to carry it out safely, with the idea of avoiding jejunal ulcer, and possibly of reducing the number of cases in which bleeding continues after gastro-enterostomy for hemorrhagic ulcer. This operation can be performed in about 50 per cent of cases of duodenal ulcer, and in these better immediate and ultimate results will follow than from gastro-enterostomy. A study of files of case histories shows that the local operation

can be done with very little risk. In 1,363 cases there was a mortality of 0.44 per cent. The procedure is limited to those cases in which the duodenum is fairly mobile. As one's experience with these cases increases, however, one realizes that it is not difficult to mobilize a duodenum that initially is fairly firmly fixed, and such mobilization should be effected in cases in which excision of the ulcer is definitely indicated. Should this not be feasible because of local conditions, in cases in which there is severe, repeated hemorrhage, then it is advisable to resect the stomach with the ulcer.

The local operation of excision of the ulcer with the cap of the duodenum and a considerable part of the pyloric sphincter, completing the operation as a gastroduodenostomy, is the operation of choice in all cases of ulcer of the duodenum, or duodenitis, and in cases of ulcer of the stomach in which the lesion is near the pylorus. In cases in which multiple ulcers are encountered, and in which it is not possible to remove all of them, it is probably best to remove the anterior ulcer, close the opening in the duodenum, and then complete the operation as a gastro-enterostomy. In operating on patients who have passed middle age, and who have obstruction of the duodenum, gastro-enterostomy gives satisfactory results. There is almost sure to be complete relief of symptoms, with little probability of the formation of secondary ulcers. This method proves satisfactory in all cases except those in which secondary ulcers develop, hemorrhage occurs, or bleeding continues.

So far as present knowledge is concerned, a person who has once had an ulcer must always be considered to have a potential ulcer. Although it is not necessary for a patient to adhere rigidly to dietary restrictions, nevertheless, at any suggestion of a return of former symptoms, he should be very cautious about his diet and activities. If he is willing to cooperate in this plan of treatment, there is no reason why he cannot be made comfortable and live a useful and active life; if he does not follow the regimen, and symptoms recur, they are likely to be much more difficult to control than the original disturbance.

When the problem of etiology of ulcer of the stomach and duodenum, and duodenitis is solved, possibly it will be necessary to change the methods of treatment in some respects. Already great progress has been made in control of these conditions, and in a large proportion of the cases it is possible to give relief from the symptoms. However, it will not be possible to assure every patient of complete and permanent cure until the exact cause of the lesions is known.

THE PROSTATIC PROBLEM*

By FREDERICK J. PARMENTER, M.D., BUFFALO, N. Y.

THE physician having a patient suffering with prostatic obstruction must assume the responsibility of giving proper advice if the future welfare of the individual is to be best served. To this end, the medical adviser should clearly understand the sequence of events which all forms of lower urinary tract obstruction eventually bring about.

The first effect is to cause hypertrophy of the bladder musculature to facilitate its emptying; and as long as the obstruction is not too great and the bladder muscle strong enough to accomplish this, all is well. This is the period of *compensation*. However, as the obstruction increases, the bladder in time becomes unable to completely empty. Residual urine results, and the period of *decompensation* is ushered in. As the residual urine increases, a back pressure is created which retards the flow of urine from the kidneys, thus preventing the elimination of waste products, and also causing slow destruction of the renal secreting tissue, until uremia and death finally end the picture.

Adenomata:—The remainder of this presentation will deal with only adenomata of the prostate, excluding carcinoma, myoma, sarcoma and all the other forms of lower tract obstruction.

The writer has termed these obstructions as *adenomata* rather than *benign hypertrophy* because in all material removed and submitted to pathological examination the report has invariably read: "Adenoma," or "Adenoma with cystic degeneration," or "Fibro-adenoma," etc., and not in a single instance has "benign hypertrophy" (which means an enlargement of the normal prostate gland) been reported. Gross examination of each specimen has also confirmed the picture of multiple adenomata of various sizes with a variable amount of fibrous tissue-supporting structure. For this reason the term "adenoma" would seem to explain the pathological condition present better than "hypertrophy," the term commonly used.

Randall in his "Surgical Pathology of Prostatic Obstructions," on page 24, refers to Marion's Treatise, in the *Encyclopedic Francaise d'Urologie* (Tome VI) upon the causes of so-called benign hypertrophy of the prostate, and in his (Marion's) summary (No. 3) states: "Those eclectics who recognize that all the glands, peri-urethral and prostatic, are able to give birth to the adenoma that constitutes hypertrophy."

Symptoms: The symptoms may be divided into two groups, namely, the urinary, which are the commoner; and the toxic, which are much more serious.

The symptoms of the urinary group begin with a slowly increasing frequency, urgency and difficulty in voiding which are worse at night, often preventing the securing of proper rest. The difficulty is usually increased by holding the urine, getting chilled, alcoholic and over sexual indulgences. Many patients state that the first voiding in the morning is especially difficult but after being on their feet a short time, it becomes much easier.

These symptoms increase as the obstruction becomes greater, until the patient has an almost constant desire to void, and the stream is thin and feeble and dribbles away. Incontinence is usual and may be constant or present only at night, resulting in the bed being constantly soaked. The final ending is acute retention, catheter relief being imperative.

Toxic Group: The symptoms in this group differ in that urinary complaints are usually conspicuous by their absence, probably due to a marked diminution in the bladder sensorium. These patients accumulate a large residual urine, with accompanying renal impairment causing uremia, which may affect any one of the other great systems of the body, such as:

Cerebral: Mental dullness, confusion, headache, dizziness.

Cardiac: Dyspnoea, especially on exertion. Decompensation with or without edema. The blood pressure may be high or low.

Gastro-Intestinal: Indigestion, anorexia, diarrhoea.

Urine: Is almost colorless, clear, with a low specific gravity.

Secondary anemia is not uncommon and may be severe.

Blood chemistry studies show a retention of nitrogenous products.

As before stated this group is by far the more serious for the reasons that renal damage is severe and may be irreparable; and because of the lack of urinary symptoms the patient has been treated for heart disease, anemia, nephritis, etc., for a long time and the true cause of his trouble missed. The following case being an excellent illustration:

Aged 70. Referred for swelling in the abdomen, pronounced by 4 medical men and one urologist as carcinoma because of its nodular feel. Patient is very weak, feeble, falling asleep when sitting in a chair. Has lost 30 lbs. in weight. Is very anemic. Has no appetite and occasional attacks of nausea and vomiting. Has nocturnal dribbling of urine.

Examination showed an adenoma of the pros-

* Read before the Ontario County Medical Society, January 12, 1932.

tate, and the abdominal swelling proved to be an overdistended bladder, the nodular feel being due to the splitting of the muscle allowing the mucus membrane to herniate through.

This patient completely recovered after a two-stage prostatectomy, re-entered business and lived eight years, then dying of heart disease. The period of drainage was $2\frac{1}{2}$ years before prostatectomy was performed. For over a year the P. S. P. test remained 0 for both hours, though the patient was eating well and regaining his weight and strength. At the time of prostatectomy this test was 32 per cent in two hours. It is interesting to note that not one of the physicians had made a rectal examination.

Diagnosis: Patients in whom the urinary symptoms are prominent offer little difficulty of recognition. Some suprapubic swelling is often present, and a rectal examination will show a typical adenomatous enlargement which is smooth in outline, freely movable, and of soft to moderately firm consistency. If the enlargement is confined to the lateral lobes alone, a deep cleft will separate them. If the median or other glandular elements are involved as well the enlargement will be felt as one mass. If only the median or subcervical or trigonal group are involved the rectal examination will be negative unless palpation is made after a stiff catheter or sound has been passed so that the enlargement can be felt between the sound and finger in the rectum. This type of obstruction must be remembered as it may cause greater retention than the large type, and because the adenoma cannot be felt, often leads to the conclusion that none is present.

These findings, together with the presence of residual urine, determined by palpation of a distended bladder or the passage of a catheter after voiding, makes the diagnosis clear.

The dangers of adenoma are toxemia from renal failure (already mentioned), infection, and carcinomatous change.

Having established the the diagnosis, what advice and treatment should be given?

The patient's condition should be explained to him; its dangers, and what can be done to relieve him. This can best be considered by making three groupings.

Group 1. The elective group. The patient has either no residual or one under 6-8 ozs., with no signs of renal toxemia or infection. If dilatation of the urethra by the catheter used to determine the residual greatly relieves in making urination freer and reduces the residual, nothing more need be done other than frequent observations to note the condition of the prostate and the return of residual urine. If the enlargement is very soft and boggy, therapeutic doses of x-ray have greatly relieved a small group of patients. Massage may also be used to advantage. Finally, the patient may elect prostatectomy before it is absolutely

necessary, to prevent future trouble and damage to his urinary tract.

Group 2. The residual is over 8 ozs., and often much more, the bladder distended, together with evidences of toxemia. Here surgical relief holds the only possibility of cure. Before operation can be safely undertaken certain investigations and preparations must be gone through, as experience has proven that the reduction in mortality from a high to a low one has been due to these factors alone, and to neglect them is just as sensible as putting to sea in a leaky boat.

Group 3. The patient has acute retention and demands immediate relief. This is the only group in which any emergency exists and even here relief can be afforded and proper time for investigation and preparation for operation spent.

Investigation and Preparation: Realizing that we are dealing with patients in the later decades of life whose bodily functions have carried the strain of years, often with its accompanying numerous infections, it seems rational that every means should be employed to determine the exact condition of the patient, thus indicating the degree of operative risk and that each step in our surgical intervention should be planned to inflict as little strain as possible. The immediate dangers of any operation are shock, hemorrhage and infection. The remote ones are non-relief of the condition for which the operation was performed.

The routine studies in our clinic are the following, and while some may consider it too elaborate, yet it has yielded much valuable information at times which could not have been secured in any other way.

First: A careful complete physical examination is made to determine the present condition of the patient and any other associated diseases as lues, diabetes, etc. Special attention is paid to the cardio-vascular system and includes an electrocardiogram. Signs of good omen are a vigorous appearance, clear eye, feeling of well being, good appetite, etc.

The urine is then examined, and if the specific gravity is 1.018 or better, we know the concentrating power of the kidneys is unimpaired. A clear urine indicates freedom from infection. The usual analysis completes this examination. If abnormal substances as sugar are present, proper treatment is instituted. Blood chemistry consists of a urea nitrogen determination, a blood sugar, and a Wassermann.

If the residual is small and the bladder can be safely emptied, a P. S. P. test is made. The dye is placed in the vein and samples are collected every half hour for two hours. Better function is present if the bulk of the dye is eliminated the first half to one hour, rather than in the second hour. A low output of dye does not contra-indicate surgery if the test has been repeated many times and its readings are constant, as in the toxic

case already mentioned. The patient is also typed. Bleeding and clotting time is also determined in case transfusion becomes necessary after operation, because of hemorrhage. We like to have the laboratory findings check with the physical ones as we consider the latter the more important. This is mentioned because the importance which has been given laboratory procedures in the past few years has led to depending upon them too much, valuable as they are.

We now come to the ways and means of reducing residual urine in the toxic group in order that surgery may later be possible. It has been emphasized for a long time that it is extremely dangerous to suddenly upset the renal balance by suddenly emptying a chronically over distended bladder. If this is done it is followed by a polyuria, then suppression and even anuria, associated with a marked increase in toxic symptoms, which may be severe enough to cause the patient to pass into coma and death. Other observers believe it is not the sudden emptying that causes so much trouble, as allowing the bladder, once emptied, to over-distend again. Whichever is right, great harm occurs when either of these things are done. There is a growing disfavor to the use of the indwelling catheter because of the injection of the posterior urethra, which may cause a fatal septicemia, and the fact that its care entails constant supervision day and night to prevent its blocking or coming out, thus causing over-distention, especially if the urine already is, or has become infected since instituting its use. Some are advocating immediate suprapubic drainage and allowing the urine to drain slowly away by partly blocking the drainage tube. These suggestions appeal strongly to the writer, especially since the recent introduction of an instrument which will allow the placing of a suprapubic tube without losing any of the bladder urine, which was practically impossible before.

A number of devices have been suggested to allow the slow escape of urine, but the grooved cork method is the most simple and the materials are always at hand, namely, a cork to fit the catheter with a groove cut lengthwise as in an ether can. This can be fitted to either an indwelling catheter or suprapubic tube and pushed in far enough to cause a steady drop of urine to flow away. This cork is then fastened to the tube at this point by piercing both with a needle and thread so the cork can not come out. Naturally this method can not be used in the presence of blood clots or thick pus. As before stated, it is imperative that drainage once established be maintained day and night regardless of how much inconvenience it may cause those in charge of the patient. The writer has seen weeks of preparation lost and even death occur from letting this condition go unrelieved.

The decompression takes from four to six days, after which the tube or catheter can be allowed

to drain freely. During this time, the toxic symptoms usually increase and must be treated by plenty of fluids, even resorting to salt solution under the skin, a favorite combination being one 20 c.c. ampoule of 50 per cent glucose and 8 c.c. of 1 per cent novocaine added to 1000 c.c. of normal salt solution, which can be given in the thighs painlessly and repeated as often as necessary.

Epididymitis, which is a serious complication and may be fatal in a feeble old man, can be prevented by vas section, with the burying of the end of one of the stumps. Epididymitis is more liable to occur if the catheter is used, and following prostatectomy.

Is cystoscopy necessary?

The writer is restricting its use more and more, especially in the clear, uninfected cases, and then carrying it out just preceding suprapubic drainage if thought necessary. If the urine is bloody or infected, the bladder should be inspected through the cystoscope to rule out stone, tumor, etc. A plain x-ray will also rule out stone, both in the bladder or kidneys. Should a study of the upper urinary tract be necessary, urography by uroselectan has much to commend it and satisfactory results can be obtained by proper technic.

Urinary antiseptics are useful at all times though they will be considerably diluted when large quantities of fluid are given.

After decompensation, an injection of 30 c.c. 1-1,000 neutral acriflavin in the tube or catheter and retained for five minutes every eight hours, helps to diminish bladder infection.

The Surgery of the Prostate.

1. Suprapubic prostatectomy in one or two stages.

2. Perineal prostatectomy.

3. Partial removal by the hot or cold punch, or desiccation as in Colling's method.

Suprapubic Prostatectomy: Suprapubic prostatectomy is employed by the majority of surgeons; and by following pre-operative preparation carefully, the mortality has fallen to about 10% on an average. Some report much lower averages—as low as 2-3%.

In the beginning, the operation was performed in one stage, but because of the high mortality, the two-stage procedure became the accepted one.

Recently there has been a revival of the one-stage method, which its advocates say permits of a visual approach in enucleation, control of hemorrhage by suture, trimming off of ragged capsular edges which may form bands in healing and later obstruction. Some also advocate suturing the mucous membrane to cover the prostatic cavity, thus lessening the chances of infection and scar tissue formation; and lastly, but one operation is necessary, so that the patient's convalescence is shorter, which is a great economic factor.

All of this sounds very plausible, but based upon the experience of many men, is more apparent than real; and also, the advocates of the one-stage operation forget one extremely important consideration, namely, that the mortality is considerably higher in the hands of the average one-stage surgeon. The writer is free to admit that try as he will, he can not be sure of just how much the patient can stand and the factor of safety is in many cases, and his experience still keeps him in the two-stage prostatectomy class, as surgical trauma is not so severe. Indeed, it is usual to have more reaction after suprapubic drainage than after prostatectomy by the two-stage method.

Hemorrhage can nearly always be controlled by a properly placed Pilcher bag; while oozing can be controlled by swabbing the prostatic cavity with Monsell's solution.

The prostatic cavity contracts rapidly after the adenoma has been removed, as the uterus does after labor, thus obliterating itself. If the bag is used, tags are pressed down and will form no obstructing bands.

The writer does not use the bag routinely but always places an indwelling catheter, which is brought out through the incision, to which a bag can be attached if necessary.

Pelvic infection has been eliminated by making an incision not over 2-2½", and not disturbing the bladder by wide stripping of perivesical tissue.

By this method the writer's mortality has been reduced to 5%, and the after results in over 95% of cases absolutely satisfactory to both patient and surgeon, which means the elimination of difficulty and a restoration of health, which is usually much better than has been enjoyed in years. It is needless to say that following each step the patient should be allowed to fully recover before further surgery is undertaken, so that taking short cuts has no place in prostatic surgery.

The time in the hospital need be no longer in the two-stage method used by the writer than the catheter one-stage procedure. In good risk patients, the preliminary catheter is not employed, suprapubic drainage is performed at once and the prostatectomy a week or ten days later, which is the time spent by the one-stage surgeon using preliminary catheter drainage; so both start convalescence after prostatectomy together. This method has the advantage if the patient has not done well, he can be sent home to convalesce. If this is necessary, the tube must be carefully watched, and if it becomes obstructed by phosphates, be cleaned or replaced, otherwise weeks of preparation will be undone. Pain and a desire to void are the symptoms present.

In the toxic cases, the writer is wavering between catheter and suprapubic decompression

with the inclination quite strongly to the latter, which future experience must decide.

Treatment after operation is just as important as before and the patient should be carefully watched for a considerable time, paying special attention to the circulatory system, kidney function, and the clearing up of any existing infection.

Pyuria may persist due to a low grade pyelonephritis, and often does not seem to impair the patient's health or cause him any inconvenience. These infections are best treated by urinary antiseptics, vaccines, etc., bladder and even kidney pelvic lavage not accomplishing much. The writer has had five patients who did not heal and had marked pyuria until infected teeth were removed, when convalescence became astonishingly rapid, going on to complete cure.

Perineal Prostatectomy: Except in a few clinics, perineal prostatectomy is not the operation of choice among surgeons. When properly performed by an experienced operator, the results are excellent. However, the danger of rectal injury, urinary incontinence and the leaving of small intravesical pieces of adenoma are by no means uncommon sequelae, even in the hands of experts.

The Punch or Desiccation Method: The final method of treatment, which will be very popular with the laity, is the partial removal of the adenoma by the punch or desiccation method. The writer uses this method for median bars, fibrous contraction, and as a palliative procedure in certain cases of carcinoma, but does not believe that the majority of patients will be benefited for any great length of time; and if the operation has to be repeated as often as seven times, as one enthusiast reports, and is not free from danger, nearly every one would rather have his trouble eliminated by open operation. Time only can determine its future place.

Anesthesia: The suprapubic drainage and vas ligation can be carried out practically painlessly under local infiltration, using 1/5 of 1% novocain. Next in choice is avertin, supplemented by local infiltration, and finally, nitrous oxide. For prostatectomy, spinal anesthesia, using Pitkin's solution; next avertin and gas; and finally, gas alone are given in order of their preference.

Briefly summarized, the success in dealing with the prostatics consists in careful attention to details, taking plenty of time to prepare the patient and proceeding step by step as indications warrant.

The actual operation is a minor consideration to adequate preparation and careful post-operative care, continuing until the patient has fully recovered, which is usually a considerable time after his discharge from the hospital. Unless the surgeon is willing to assume such responsibility, his results will never compare with the man who does.

CLINICAL ANALYSIS OF PROSTATIC OBSTRUCTION

By DENVER M. VICKERS, M.D., AND STANLEY T. FORTUINE, M.D., CAMBRIDGE, N. Y.

From the Urological Clinic of the Mary McClellan Hospital, Cambridge, New York, Benjamin S. Barringer, M.D., Consultant.

PROSTATIC surgery is essentially a modern procedure being developed and popularized in the past 25 years, in spite of the fact that the anatomical knowledge of the prostate dates back two centuries. Historically, too, there are a few records of partial removal of the median lobe during the middle of the last century, but the mortality was usually 100 per cent, the cases isolated, and the technique variable, and the operation has attained wide practicability only in the last few years.

The first suprapubic prostatectomy, as we now understand the term, was done in this country by Eugene Fuller of New York, in 1894, and in 1900 Freyer reported 4 successful cases in the *British Medical Journal*. Young introduced the idea of counterpressure in the rectum in 1898. From this beginning, all our present technique arises.

But for the first decade or two, results were uncertain, in spite of standardized operative technique, and figures of mortality varied widely. Many patients and many surgeons too were rightly afraid of the operation.

Keyes as late as 1923 stated that the mortality of the operation in the hands of the average specialist was 10 per cent, and when done by the general surgeon, 50 per cent. But increasing knowledge of the pre-operative technique, of the importance of estimating the kidney function, of the many details to be covered before the operation itself is performed, have greatly lowered this mortality, and this paper demonstrates what results may be expected in the hands of a general surgeon.

The technique of prostatectomy, therefore, is not so much in the performance of the operation, as it is in adequate preparation in the days and weeks before operation. The pathological physiology of prostatic obstruction shows that the urine held in the bladder backs up in turn on the urine in the kidney pelvis, so that the excretion from the kidney is done at an increasingly higher pressure. This brings about a type of nephritis, with rise of blood pressure, increased nitrogen retention in the blood stream, and decreased kidney function tests.

This condition of back pressure brings about a special difficulty, for if the pressure in the bladder is released too suddenly, the secretory balance may be so quickly thrown out of adjustment, that the kidney will cease to function altogether. Clinically this means that we "decompress" gradually, by intermittent catheterization, at the beginning of treatment, with withdrawal of only a portion of the retained urine, and gradually decreasing the amount of residual over a period of

hours or days. Or we may introduce a constant drainage tube, and so arrange the apparatus that the stream flows up-hill, with the drainage bottle above the level of the patient. This then is gradually lowered to drain in the usual fashion. It is true that the more severe the nephritis due to prostatic obstruction, the greater the chances of sudden collapse following complete emptying of the bladder.

Clinically, these patients show the signs of kidney toxemia coupled with urinary retention, total or partial. This implies difficulty in voiding, difficulty in starting the flow of urine, frequency by day and night, dribbling and even complete retention. These symptoms coming on in an elderly man accompanied by physical signs of urinary toxemia and an enlarged prostate as palpated through the rectum, usually make the diagnosis of prostatic obstruction. Stricture is ordinarily a disease of younger life and in differential may usually be excluded.

Of prognostic value, the general condition of the patient is of greatest importance. Is his myocardium too much involved? Is he losing or gaining weight and strength? Is he able or willing to take adequate fluids and nourishment?

Of specific indices, the range of the blood pressure is of prime importance, and operation should not be performed until the blood pressure is stabilized. After drainage is instituted, the pressure ordinarily falls, sometimes drastically, but is followed in a few days, in the favorable cases, by a secondary rise to a point somewhere near the old level. Operation in this period of hypotension (hypotension, at least, in relation to the pressure before) is fraught with danger, and should be postponed till secondary stabilization occurs.

The old reliable "phthalein" or "red" test, is of value, and after drainage this test often improves remarkably, occasionally coming up from 10 per cent to 40 per cent, rarely reaching the 50 or 60 per cent mentioned as normal in the text books.

The nitrogen retention in the blood stream ordinarily determined as the N P N, or non-protein nitrogen is another common laboratory test of kidney function. A level above 40 mg. per 100 cc. (the theoretical normal being 30) is a sign of difficulty. If it is high and stays high, avoid interference. If it is high and comes down under treatment, then you are enabled to go ahead.

The ordinary tests for albumen, casts, etc., are not of great significance, especially by their absence. A patient with a perfectly negative urine analysis may show all the functional indices markedly impaired.

Drainage of the bladder, to avoid the obstructing prostate is done in one of two ways. Catheter

drainage, with a tube in the urethra, is the simplest and easiest, and often is most satisfactory for the patient. If this is not tolerated well or if the urethra cannot be entered with a catheter, as occasionally occurs, a suprapubic cystotomy is done, with a drainage tube sewed into the bladder above the symphysis.

After satisfactory drainage is instituted by one means or another, the patient is encouraged to drink, so that the total intake per day is above 3000 cc. and as much more as possible. If fluids cannot be taken by mouth, they are administered through the bowel, under the skin, or into a vein. This period of forced fluids is often life saving. In addition, a nephritic regime is instituted, with restriction of the protein intake, etc.

The drainage tube is left in until the kidney function tests have come more nearly to normal, and until the general condition of the patient improves, so that he is able to be up and about, to walk short distances, and to show the cardiac and vasomotor decompensation, which usually accompanies prostatic obstruction, partially restored. This period varies from five days to three months, apparently without changing the ultimate prognosis.

The period of preliminary drainage, testing of the kidney function, and estimating the patient's general condition is of greatest importance. The results of this period determine the prognosis more than does the actual operative technique.

The operation itself that we perform in this clinic is the suprapubic prostatectomy. Perineal prostatectomy may have it advantages, especially in the hands of one accustomed to it, but the suprapubic operation we have found satisfactory and well adapted to the use of the general surgeon.

The anaesthesia for prostatectomy is habitually spinal. Ether we avoid. Sacral is usually not sufficient. Gas-oxygen is efficient for short periods, but raises the blood pressure. Spinal has been satisfactory, and we continue to use it.

For the drug, we like straight novocaine in doses of around 100 mg., giving a low anaesthesia, with care not to force the solution too high; or nupercaine, which gives a longer anaesthesia, lasting five or six hours after operation. Nupercaine is said to be considerably more toxic than novocaine, but has given good results in our hands. On a simple cystotomy, local novocaine may be used.

If the operation is in one stage, the bladder is opened in the mid-line above the symphysis, the mucous membrane grasped with retention sutures or Allis clamps, the urine or boric solution evacuated, and the prostate enucleated manually, with one or two fingers of the right hand in the bladder, and two fingers of the left in the rectum to give counter pressure. Bleeding is usually moderate, but the cavity of the prostatic bed is usually

packed with gauze, and at times a forceps is left in position on the gauze to give pressure if needed. In the ordinary case, this packing is probably unnecessary, though usually we have not the courage to omit it. It seems to do no harm, and is removed with little difficulty in 24 or 48 hours, and the surgeon sleeps better the first night. In the two-stage operation, the enucleation of the gland is carried out several days or weeks after the preliminary cystotomy.

Sutures of the prostatic bed, visualization of the field of operation, and removal with cutting instruments are usually unnecessary, give additional trauma without aiding the end results, and we depend more and more on manual dexterity.

Tabulating our own cases over the past few years, we find 56 patients admitted to the hospital with the diagnosis of prostatic obstruction. Of these, ten were clinically or pathologically carcinoma, that is, 18.2 per cent. This ratio agrees approximately with reports elsewhere. Approximately one obstructing prostate in five is malignant. The clinical texture of a carcinomatous prostate felt through the rectum is usually unmistakably firm or hard. These patients often have pain out of all proportion to the urinary obstruction. They frequently have metastases to bone. They rarely have hematuria. The average age of our ten was 69 years, varying from two at 53 to one at 79. Of these, three were in for diagnosis only, two were treated with radium only and five have suprapubic removal of at least the obstructing portion of the gland with radium post-operative, either in the prostatic bed or through the perineum. Of these patients, one died in the hospital, two died shortly after, and several have been well over three years.

Of the others, six had nothing done; were admitted only for diagnosis, had only slight or partial obstruction, or did not prefer to be operated on. None of these died.

Six others had catheter drainage only; were obstructed, but in no condition according to the clinical tests, to undergo operation. Three of these died; three went home with catheters in place or at least intermittently inserted.

Of the remaining, three had suprapubic cystotomy only; that is, the bladder could not be emptied with a catheter and an opening was made above the symphysis. These three were all old men, averaging 83 years, had an average N P N of 104 and all died after intervals of 4 to 56 days. Removal of the gland itself was not attempted in any of these groups. This mortality, of course, justified our decision to avoid radical interference.

This leaves 31 who had a prostatectomy, 14 with one-stage and 17 with the two-stage operation. One died post-operative in each group, that is a mortality of 2 out of 31 or 6.4 per cent. One was a death from embolism, which may follow any

major operation. The other was questionably malignant, and the operation technically difficult.

The average age of this group was 69.3 years, varying from 56 to 83. The fact that these old men, almost 70 years of age, can go through a major procedure such as this in any fashion at all, is interesting and almost spectacular. No patients are more grateful than prostatics when relieved of their symptoms.

The average blood pressure was 155 systolic. This does not seem too high for men of 70, but it is the stability and not the actual level that seems to be of importance. The average N P N on admission was 47.5 mg. per 1000 cc. of blood, but this was reduced below 40 in most cases before operation.

The average preoperative stay in the hospital was 26.7 days. This is the time when the kidney function is built up. It varied from 6 to 69 days, and, we repeat, operation was postponed until the clinical tests were favorable.

The post-operative stay averaged 42 days, this average being increased by a few slow healing cases, many leaving the hospital in two or three weeks. These patients were allowed out of bed very quickly after operation, often long before the wounds healed. We ordinarily use no indwelling or retention catheter post-operative, simply allowing the suprapubic wound to close by granulation, coincident with the establishment of the ordinary urinary flow.

We append the following case to illustrate some of the complications which must be considered in prostatic disease.

J. S., age 75, was admitted to the Mary McClellan Hospital, August 9, 1931, referred by Dr. W. A. Leonard of Cambridge, New York.

The patient, on the morning of admission, was in acute cardiac distress, breathing with great difficulty, and complaining of pain in the right side of the chest, in the precordial region, and in the left arm. The pain was so severe that it was only partially relieved by large doses of morphine and nitroglycerine. The pulse was between 110 and 130, and of poor quality. Blood pressure upon admission to the hospital was 184 systolic and 90 diastolic, and in the course of the next twenty-four hours fell rapidly to 110 systolic 60 diastolic. For thirty-six hours after his admission to the hospital, he ran a fever of 101 to 102. Leucocyte count was 17,200. His pulse showed the irregularity of auricular fibrillation. The first sound at the apex was of a peculiar scratchy character suggestive of a friction rub. There were numerous rales through the chest, especially at the left base. For this cardiac condition, he was seen in consultation, by Dr. L. W. Gorham of Albany, New York, and a diagnosis of coronary thrombosis made. In the course of the next few weeks he gradually improved.

About a month after his admission he had a partial hemiplegia, involving the right arm and leg and the power of speech. This cleared up rather rapidly in the next twenty-four hours.

The genito-urinary history dates back ten years, when he first began to notice nocturia, frequency, and some difficulty in passing his urine. This gave him moderate trouble up to the time of his admission for angina pectoris.

Rectal examination showed a diffusely enlarged prostate of benign hypertrophy. His kidney function was fairly good, his Non-Protein Nitrogen being 58.82 mg. per 100 cc., his blood chlorides 429.04 mg. per 100 cc. His blood Non-Protein Nitrogen gradually came down until it reached a level of 40.64 mg. per 100 cc. The output of phenolsulphonephthalein in two hours was 40 per cent. Residual was 1000 cc.

A permanent catheter was introduced into his bladder through the urethra and kept in place, being occasionally changed.

He was kept in the hospital, in bed, practically all of the time from his admission on August 9th, until the first of December. The entire situation was then carefully explained to the patient, telling him that unless the prostate was removed he would have to use a catheter continually or have a suprapubic drainage done. The dangers, also, of operation, in view of his past cardiac history were gently explained to him, but he decided that he would rather take the risk than go on the rest of his life with a catheter.

He was, therefore, operated on, under spinal anaesthesia, the prostate being removed in a one-stage operation, through the suprapubic route. The prostate was adherent to the neighboring structures by bands of scar tissue. He stood the operation better than was expected and in the course of a few weeks was beginning to void normally.

He has been seen on several occasions since. His wound is entirely healed. He voids in the normal way without difficulty, showing a good stream of urine. He has nocturia about one a night. Otherwise he shows no urinary disturbance of any kind. His heart action is good. Occasional extrasystoles are noted, but his blood pressure is well sustained at about 135. He is walking around, going out of doors, taking short automobile rides, and is very comfortable and happy.

SUMMARY

	No. of Cases	Deaths
Benign Hypertrophy:		
One Stage Operations	14	1
Two Stage Operations	17	1
	—	—
Total Complete Operations	31	2
Cystotomy only	3	3
Catheter Drainage only	6	3
No Operation	6	0

Carcinoma of Prostate:		
Removal and Radium	5	
Radium only	2	
Diagnosis only	3	
	10	1
	<hr/> 56	<hr/> 9
Totals		

Of the patients in this series, with benign hypertrophy of the prostate, the mortality in those

having the complete operation was 6.4 per cent.

From this group of operatives, we excluded a number with poor functional tests, and did a simple cystostomy or established catheter drainage. The mortality in this small non-operative group was 67 per cent. This shows the need for careful selection of cases.

In our series, 18.2 per cent of obstructing prostates were clinically or pathologically malignant.

TREATMENT OF THE AMBULATORY DIABETIC PATIENT*

By EDWARD TOLSTOI, M.D., NEW YORK, N. Y.

From the department of Metabolism of the Cornell Clinic and the department of Medicine of Cornell University Medical College.

EVEN though the management of the diabetic patient is always changing, the basic therapeutic principle remains the same. This foundation upon which all successful treatment of diabetes rests is *undernutrition*. It matters little what particular method in use one adopts to obtain satisfactory results, the restriction of the total caloric intake compatible with the patient's requirements, is of paramount importance. This fact was not generally appreciated until Guelpa² and Allen¹ introduced the *undernutrition* treatment. For the first few days of the treatment Allen reduced the intake of utilizable food to such a low level that the patient practically starved. To allay the pangs of hunger, so-called "fillers" were used. These consisted of bran, agar jellies and thrice-cooked vegetables. After a few days of this regime the urine became free of sugar and ketone bodies, and the distressing clinical symptoms such as thirst, urinary frequency, fatigue, sleepiness, visual disturbances and pruritus decreased in severity or disappeared entirely. The patient was then given a diet so low in calories that a steady reduction in weight ensued. The results were most gratifying at first. As the treatment progressed, the patient began to rebel. True, there were no symptoms to annoy him, but the progressive emaciation and hunger proved too much for even the more cooperative individuals. Their bodies were reduced to skin and bones, their ankles became puffy and their loss of strength was distressing. The urine, however, remained free of sugar and ketone bodies and the blood sugar dropped and remained close to a normal level. All of this was grand for the diabetes, but what about the poor patient? One could always point with pride to the records but even a casual glance at the patient failed to impress the most open-minded observer too favorably. Allen's method, though demanding, established beyond doubt that it had merits. During its period there

was a reduction in the number of severe cases, the frequency of coma was decreased, and also the life or existence of the diabetic patient was prolonged.

In spite of the promising results obtained by the extreme undernutrition method, physicians began to wonder whether the result justified the means. Wasn't there some alternative to starvation? Couldn't something be done to make the patient more comfortable? Most men felt that the patient should be given a more liberal diet, but what kind of a diet? At that time all agreed that carbohydrates were to be limited. Warnings against too much protein were sounded by Joslin³ who noted that much protein made a mild diabetes more severe. His clinical observations were substantiated by experiments at DuBois⁴ laboratory and by Wilder, Boothby and Beeler⁵ at the Mayo Clinic. Both groups noted that their subjects exhibited the severest diabetes when on a high protein diet.

What about fat? Didn't physiologists state that the combustion of fat was incomplete in diabetes, so that ketone bodies were produced and these may have been responsible for the resulting coma? That dictum was accepted. Newburgh and Marsh⁶ of Ann Arbor argued, however, that it was no more harmful for a diabetic patient to burn, or attempt to burn fat supplied to him than use his own. And, consequently, they devised a diet *high in fat*, but low in protein and carbohydrate. They were wise enough, however, to keep the total caloric intake below the basal level so that the principle of undernutrition was maintained. They placed their patients on an initial diet of 10 grams of protein, 90 of fat, 14 of carbohydrate, a total of 900 calories. They claim that this diet enabled the patient to "lead at least a moderately active, comfortable life." As the glycosuria subsided and no evidence of ketosis appeared the diet was increased to 1400 and 1800 calories keeping the protein and carbohydrate at a maximum of 30 and 40 grams re-

* Read before the Cornell Clinic Staff, Department of Medicine.

spectively. A similar diet has been used by Petren⁷ of Lund, who was also enthusiastic over its success.

At this stage of developments came the discovery of insulin by Banting and Best.⁸ The diabetic patients were overjoyed. Now they could eat more, perhaps as much as other people. Their bodies would take on flesh and they would regain their strength. While the knowledge of the use of insulin was being developed they patiently waited. It was then that a group of observers from California under the leadership of Sansum⁹ published an account of experiences with a high carbohydrate diet with the use of insulin. In this city Geyelin¹⁰ used similar procedures and was quite pleased with the results. It was their belief that a diabetic patient's dietary should approach the normal one as closely as possible, enough insulin being given to insure the use of the food above the patient's tolerance. In some cases as much as 200 units were used daily. Such diets containing often 100 grams of protein, 125 of fat, and 250 of carbohydrate, certainly appealed to the diabetic who for years had been dragging out his existence on 50 to 60 grams of carbohydrate.

Most patients might have enjoyed this regime but it proved rather expensive and somehow the method did not have the same appeal to physicians. It did encourage the use of more liberal amounts of carbohydrate in the diabetic diet and from the careful clinical and experimental work, certain hypotheses were postulated. It was brought forth that diabetics whose carbohydrate rations have not been too low even though a glycosuria existed, lived longest; that a drastic reduction of the carbohydrate may precipitate coma, and that normal men and animals show temporarily at least a lowered tolerance to carbohydrate when living on a low carbohydrate high fat diet. This I¹¹ too demonstrated with Steffanson and Anderson, both of whom lived for a year on a diet of protein and fat—exclusively meat. At the end of the experimental periods both men showed a diminution in tolerance to glucose. The ability to use carbohydrate returned after two weeks of a general diet. This, and other similar experiments by Porges and Adlersberg,¹² demonstrated, I believe, that the normal carbohydrate mechanism needs adequate daily stimulation and if this stimulus is withheld the insulin secreting function lags behind. It is easily appreciated why more physicians began to use a liberal carbohydrate diet in the treatment of diabetes. Porges and Adlersberg are great advocates of a high carbohydrate low fat diet. Their clinical experiences show that a diet of such composition elevates a diabetic patient's tolerance to glucose. This view is now shared by many. Joslin's³ present day diet contains six times the quantity of carbohydrate compared to his diet in 1915. With the increase he prescribes 23 units of insulin.

Rabinowitsch¹³ of Montreal uses diets of 250 grams of carbohydrate with a minimum of 45 to 50 grams of fat. All of his diets are based on the undernutrition principle in spite of the generous portion of carbohydrate. He has treated over 500 cases with such diets and reports excellent results. Some of his patients required as little as 5 to 10 units of insulin daily.

From our experiences at the clinic I can aver that the patients enjoy high carbohydrate rations. Before discussing the method we employ it is important to stress that undernutrition is our guiding principle irrespective of how we dress it.

In our clinic we are particularly interested in the patient's eye-grounds, blood-pressure, weight and condition of the arteries, in addition to the routine physical examination. We then briefly explain the nature of the disorder, stress co-operation, and discuss some of the hazards connected with carelessness in the diet. The patient is then told what and how much to eat. In planning a diet we use household measures such as cupful, teaspoonfuls, etc., in preference to having the patient weigh everything. Weighing the diet is not very feasible as we have traveling men stenographers, bank clerks and men in every walk of life, living in rooming houses and eating most of their meals in restaurants. The patients prefer simplicity. It is our aim, of course, to prescribe a minimum of 30 calories for each kilogram of the standard weight, and increase this as the individual needs warrant. Most often, however, we commence with less. We advise from $\frac{2}{3}$ to 1 gram of protein per kilogram, the fat being kept at a minimum and the quantity of carbohydrate is rather liberal. It is appreciated that we must experiment with each patient's diet but we must arrange his diet so that *he* is satisfied. Let us assume that a man weighing 170 lbs. comes to us because of a glycosuria. Diabetes is suspected and confirmed by the examination of the blood. The patient's expected weight is 155 pounds or 70 kilograms, and on that basis the diet is planned. Calculating the protein at $\frac{2}{3}$ of a gram per kilogram he is to have about 50 to 60 grams of protein, and though we would like to place him on 2100 calories we must use less at the beginning, let us say 1400 to 1500 calories. We will, therefore, plan a diet of 60 grams of protein, 60 of fat and 125 of carbohydrate. Having formulated this trial diet we proceed to translate our figures into a language the patient appreciates. To outline his menu we must learn certain food values, for example, a Uneda biscuit contains 5 gms. carbohydrate. Two such biscuits equal the carbohydrate content of a small orange. About 4 tablespoons of cooked oatmeal contains 10 gms. Two saucers of 5% vegetables or 1 saucer of 10% contain 10 grams; one slice of bread about 15 gms.; etc. We then tell the patient that his specific diet is, for example:

Breakfast

- 1 orange, orange juice or $\frac{1}{2}$ grapefruit
- 2 eggs
- 4 tablespoons of oatmeal
- 1 slice of bread or toast, buttered
- Tea or coffee with 1 tablespoon of cream

Lunch

- 2 slices of ham or 1 tablespoon of salmon or 2 slices of American cheese
- 2 saucers 5% vegetable
- 1 saucer 10% vegetable
- 1 slice of bread
- 1 fruit

Dinner

- Clear soup
- A portion of meat, fish or chicken
- 2 saucers 5% vegetable
- 1 saucer 10% vegetable
- 1 slice of bread buttered
- Salad made of 2 leaves of lettuce and 3 slices of tomatoes Vinegar and lemon juice dressing
- Tea or coffee with 1 tablespoon of cream
- Fruit

In addition to dietary instruction the patient is taught how to examine his urine and at first we encourage him to bring us records of the analytical results. Most of our patients become interested in all procedures and the task in a majority of cases is relatively simple. The more the patient knows about diabetes the less difficult it is to treat him and we do all we can to educate him. As the clinical symptoms improve and the urine is free of sugar the diet is gradually increased so that the patient's calculated caloric requirements are met. Actually we keep a bit below this as the patient is inclined to eat a little more than prescribed.

The majority of our patients are mild or moderately severe cases presenting no difficulties. The more severe diabetics must have insulin. They are taught how to administer the hormone to themselves, as well as the symptoms and treatment of an overdose. Some cases in spite of all our efforts and threats continue to go downhill. At first we suspect them of dietary indiscretions and very tactfully suggest adherence to our prescription. As the glycosuria persists we accuse

them of breaking their diets, and since we cannot control them by seeing them once or at most twice a week, we advise hospitalization. Usually our advice is rejected. They feel well, we are told, and as they have no subjective symptoms, to them, entering a hospital is a waste of time and money. Some do not return to the clinic if we insist on hospitalization, while others accept our advice reluctantly. After a two or three week stay at the hospital they return to the clinic still showing heavy traces of sugar in the urine and apparently little benefited by the hospital stay even though the hospital records reveal a lowering of the blood sugar and the absence of sugar in the urine and almost always a loss of weight. When we express our disappointment over the fact that their clinic record is not as attractive as the hospital one, they reply, and truly so, that it is impossible for them to imitate the hospital regime while in pursuit of their daily occupation. Being served in bed contrasts sharply with chasing subway eating in cafeterias and competing for a job.

Such patients are real problems. It is obvious that we must modify our treatment to suit such patients' circumstances and at the same time attempt to control the diabetes. This requires much modification with frequent changes of the diet and the quantity of insulin. The results are slow, but we find that gentle persuasion, patience, and understanding the patient's philosophy help considerably.

We must constantly bear in mind that even though we are always aiming to give the patient fewer calories than he requires our policy must be flexible lest in our scientific enthusiasm we become so oblivious of the patient's needs to carry on that our treatment becomes a greater hardship than the diabetes.

In summary, our method at the clinic of treating a diabetic is based chiefly on the principle of undernutrition. We are employing a high carbohydrate low fat low caloric diet, we attempt to educate the patient so that he learns to judge his diet, and examine his urine, we acquaint him with the use of insulin as well as the symptoms and treatment of an overdose. We stress cooperation but at the same time we try hard to see his point of view.

HEAD INJURIES

By HENRY H. RITTER, M.D., NEW YORK, N. Y.

From the Department of Traumatic Surgery, New York Post-Graduate Hospital.

THE number of cases of injury to the cranium and its contents has increased with the advent of this highly mechanical age and the era of rapid transportation. For many years much stress has been placed upon fractures of the skull per se, yet the fracture is rarely the cause of trouble unless a fragment of bone has been jammed into the brain or is compounded, adding the danger of infection. Hence, too much attention need not be paid to the uncomplicated fracture. It is damage to the cranial contents resulting in edema, laceration or contusion of the brain or intracranial hemorrhage that requires care and attention, not forgetting concussion, the true pathology of which is still in doubt.

Injuries to the head may be divided into

1. Injuries to the scalp.
2. Injuries to the cranium.
3. Injuries to the intracranial contents, and
4. Any combination of the above.

SCALP

Injuries to the scalp may be divided into

- a. Contusions.
- b. Wounds.

The thick skin of the scalp is solidly bound by tough, fibrous septa to the epicranial aponeurosis, or galea aponeurotica, and this in turn is only very loosely attached by areolar tissue to the pericranium. As a result, the skin can not be detached from the aponeurosis, though the latter can very easily be torn from the skull, and a potential space is always present beneath the galea in which infection or hemorrhage can spread without hindrance from the superciliary ridges of the frontal bone to the superior curved line upon the occiput.

The scalp, because of its excellent blood supply, is resistant to infection and wounds thereof heal readily. Contusions are associated with hematomata which may be subcutaneous, intramuscular, subaponeurotic or subperiosteal. Subperiosteal hematomata, because of the attachment of the periosteum, remain limited to the area of one bone. The subaponeurotic hematomata may spread over a wide area from the forehead to the occiput and to the lateral sides of the head. The other forms of hematomata, because of the structure of the scalp, remain localized. It is often difficult to differentiate between a depressed fracture of the skull and a hematoma of the scalp by physical examination. The differential diagnosis is made, at times, by noting

that in depressed fractures the edges are usually rough, irregular and sharp, while in hematomata they are smooth and quite regular around the circumference of the swelling and on occasions may be movable. The use of the radiograph is, of course, of great value, though a negative x-ray does not rule out fracture. An hematoma may be caused by a fall or blow upon the head with a blunt object. The hematomata of childbirth are the result of prolonged pressure.

Though hematomata usually disappear, absorption may be hastened by elastic pressure, wet dressing and a firm bandage. Rarely, blood serum remains encysted and aspiration or incision is indicated. Watchful waiting and careful observation for the possible development of abscess are essential. Early evacuation of an abscess or broken down hematoma with free drainage is indicated.

Wounds of the scalp are sustained, described and treated as wounds in other parts of the body. Scalp wounds bleed freely and so have a tendency to carry any foreign material out of the wound. Blood vessels in the scalp are difficult to clamp because of their tendency to retract. Bleeding is controlled by either pressure, suture or packing. In the treatment of wounds, it has been our custom to give the scalp a dry shave, cleanse the wound and the surrounding tissue with either gasoline, benzine or kerosene to remove all grease and grime and then flush the wound with full strength tincture of iodine. If treated early, the incised wound is immediately closed with interrupted non-absorbable suture material and drained for twenty-four hours. In the contused or lacerated wounds, after the iodine flushing a thorough debridement is practiced and then the wound is sutured and drained for twenty-four hours. Badly bruised and devitalized tissues are easily infected, hence the necessity for complete debridement. Wounds seen two hours after an injury or later are either allowed to remain open for forty-eight hours and then sutured or are sutured loosely and are always drained. Drainage material should be either rubber tissue, rubber bands or strands of suture material and never gauze. In all infected wounds, sutures are removed early, adequate drainage instituted and a wet dressing applied. Infection is extremely dangerous and may easily be carried into the blood stream or to the brain. Occasionally infection attacks the skull and causes an osteomyelitis which is most resistant to treatment. In children, it is sometimes possible to bring the edges of the wound together by tying several strands of hair on either side of the wound to one another. A sterile gauze dressing is then applied.

* Read before the Cortland County Medical Society on October 30, 1931.

Wounds of the scalp heal readily and sutures should be removed early.

Fractures: Fractures of the skull are divided into those of the vault and of the base, but of course a fracture of the vault may extend to the base and vice versa. They are further divided into linear fractures and depressed fractures and may be either simple or compound. Fractures of the base are by far more common than fractures of the vault. LeCount and Apfelbach,¹ in a study of 504 autopsies upon fractures of the skull, found that 85% were the simple linear type and that 15% were extensively comminuted or depressed, "with the bones of the cranial base involved in varying degrees in all but 8% of the 504." McCreery and Berry² in 111 autopsies found the base involved in 44, the vault in 15 and the vault and base in 52. Rest, ice bag to the head, a light diet and quiet are indicated in the simple, nondepressed fracture without intracranial involvement. It has been our practice to keep such patients in bed for a period of from two to three weeks and if necessary, sedatives such as luminal, grains ss, or bromides grs. XXX, are administered for restlessness and headache. Recently, the writer was present at an autopsy performed upon a patient who had sustained a simple fissured fracture of the skull. Two hours after admission to the hospital he was symptom free and against the advice of the doctors insisted upon leaving the hospital five days after the injury. On the day following his arrival at home, he lapsed into unconsciousness, developed a unilateral paralysis and died. At autopsy an old extradural blood clot was encountered, an extensive fresh extradural hemorrhage and a fissured fracture of the skull with a recent tear of the middle meningeal artery. Apparently, there was originally some extradural hemorrhage with which the patient could cope, and it was the consensus of opinion that the excitement attendant upon going home caused a secondary hemorrhage and death.

In the simple depressed fractures without intracranial damage there is some difference of opinion as to treatment. By some it is claimed that depressed fractures, unless evidenced by focal signs or signs of intracranial damage, require no surgical interference since the brain will accommodate itself. We are of the opinion, however, that all depressions that are definitely visualized by the radiograph and palpable on physical examination should be raised without regard to the site of the fracture. The inner table of the skull is always broken to a greater extent than the outer and the amount of depression of the outer table is no sign of the extent of the displacement of the inner. We have always felt that though no focal signs are present, the continued pressure of bone upon the brain and its coverings must result in definite

damage to these structures. In raising depressed bone every effort should be exercised to prevent damage to the brain and meninges. No bone should be removed unless it appears devitalized or cannot readily and safely be replaced. All agree that depressed fractures with focal signs should be operated upon early and the bone raised or removed.

In compound fractures of the vault and in fractures of the base of the skull communicating with the nose, throat, ears or sinuses, the danger of infection is always present and though primarily no intracranial damage exists, infection of the coverings of the brain or infection of the brain itself may follow and not infrequently with fatal results. Compound fractures of the vault of the skull are treated as wounds of the scalp and at the same time the exposed bone is inspected. It is easy to tell a fissured fracture from a suture line because fracture lines always bleed. If the bone is depressed, in cases seen early, it should if possible be elevated immediately. No bone that remains covered by periosteum and attached should be removed unless there are definite indications therefor. When a suspicion of infection appears, free drainage must be allowed. In fractures of the base of the skull accompanied by bleeding from the orifices, no attempt should be made to stop the hemorrhage or the discharge of cerebrospinal fluid since the patient is decompressing himself and packing may prevent drainage and result in intracranial pressure. We do not feel that the ears or nares should be irrigated. The installation of a few drops of 3½% tincture of iodine into the orifices is good practice. Blood clots should be gently removed with forceps or curette. The diet should be light, sedatives used sparingly and urotropin grains 7½ administered every four hours. Of course, an ice cap to the head and quiet are indicated together with proper hygiene. It is difficult to imagine a blow upon the head sufficient to cause a fracture not causing some cerebral damage, yet all of us have seen marked intracranial damage without fractures of the skull and no intracranial damage with fracture.

Retrostastoid or subconjunctival ecchymosis appearing late is pathognomic of fractures of the base of the skull.

Watchful waiting and careful observation are essential in the treatment of skull fractures.

DAMAGE TO THE INTRACRANIAL CONTENTS

The normal spinal fluid pressure varies from 6 to 10 mm. of mercury and can be measured by a mercury monometer attached to a lumbar puncture needle. Cushing³ has definitely proven that the effect of intracranial pressure is not compression of brain tissue, but interference with circulation to the brain. In the care of head injuries, primary attention must be directed

toward the treatment of shock and no attempt made to establish a diagnosis until the patient's condition warrants it.

The simplest form of cerebral lesion resulting from trauma is *concussion*. No basis exists for the term lesion since no definite pathologic findings have ever been ascertained. Many theories have been expounded, such as temporary inhibition of cortical functions, generalized cerebral anemia and multiple very fine hemorrhages within the brain. Vance⁴ feels that "all that can be said about this condition, as far as its etiology is concerned, is that the violence in some way jars the brain and that the cerebral centers are depressed. It must be regarded solely as a clinical entity with a pathologic basis which our present methods of examination cannot demonstrate." Yet concussion presents a definite symptom complex and runs a more or less typical course. Concussion is entirely limited to those cases of intracranial damage that do not show signs of intracranial pressure, hemorrhage, laceration or contusion of the brain. The symptoms are immediate and generalized and involve a disturbance of consciousness extending from a simple state of lethargy to deep coma; yes, from "seeing stars" to death. The prize fighter who is "knocked out" by a punch on the jaw or a person who "sees stars" from a blow on the head is suffering from concussion. There may be present a picture of shock with pallor, dilated pupils, rapid thready pulse, normal or lowered blood pressure, superficial respirations and either an absence or diminution of reflexes. The spinal fluid pressure may be normal and no change in the spinal fluid noted. With the return of consciousness, headache, vertigo, vomiting and loss of memory for events immediately preceding or causing the injury and disorientation may follow. The treatment is dependent upon the severity of the concussion. Many patients react readily if left severely alone. Others will require some stimulation, such as the administration of whiskey, caffeine, etc. More severe cases require rest, heat, forced fluids, avoidance of external stimuli, luminal or codein for restlessness and headache and shock position. A solution of 500 c.c. to 1,000 c.c. of 5% glucose or normal saline by hypodermoclysis or infusion is at times of great value. The period of bed confinement is dependent upon the severity of the concussion. Headache, dizziness and disorientation are the commonest sequelæ and I might add that these complaints though frequently seen in compensation cases are not limited to that group of patients. In a series of 500 cases of death from head injuries, Vance⁵ found 139 due to concussion, the majority dying within the first hour.

Contusions of the brain may cover a larger or smaller area and present the same symptoms as noted in concussion, with the possible excep-

tion that they are more severe and of longer duration; there may be some twitching of the extremities. The temperature may be normal or subnormal. The spinal fluid will be bloody and under increased pressure, providing of course that the patient has reacted from the shock of the injury. Subarachnoid or pial hemorrhage is present. The duration of the symptoms is variable.

Laceration of the brain is a severe injury associated with unconsciousness, which is usually immediate, profound and of long standing. After the shock of the original injury has passed, there is a rise in temperature to 103° or 104° F. Early fever is a sign of laceration. Irritability, restlessness, twitchings and spasms of the extremities may be present depending upon the area involved. In other words, all signs of cortical irritation are present. A spinal tap will show bloody spinal fluid and usually under pressure.

Cerebral Edema is definitely associated with intracranial damage. As a result of the edema, there is interference with the venous flow and the absorption of cerebrospinal fluid. An actual increase in the amount of spinal fluid follows and further increases the spinal fluid pressure. As the pressure increases, the arterioles within the brain are compressed and an anemia of the brain results. The signs of compression will depend upon the amount of intracranial pressure. There may be slight headache and drowsiness and possibly some focal signs. With increasing pressure, there is headache, vertigo, restlessness, excitement, delirium and occasionally cyanosis. As the pressure continues, the pulse rate slows, there is some dilatation of the retinal vessels and the skin is warm and dry. Later, the pulse rate may drop as low as 40, respirations become noisy, irregular and of the Cheyne-Stokes type. When the pressure reaches a point where the brain no longer accommodates itself, the pulse becomes rapid, respirations irregular and rapid, the pupils dilate and become fixed, coma deepens and death follows.

In *intracranial hemorrhage* of the extradural type, symptoms of pressure are observed. In cases where the hemorrhage is under control there may be no signs. As a rule, the onset of unconsciousness is slow, or if the patient is immediately rendered unconscious, there may be a lucid period followed by deepening coma. Twitchings, paresis or paralysis, and irritation of the cortical cells may be noted and aid in localizing the lesion. In a study of 908 skull fractures (547 demonstrated as such) Moody⁵ found that there were 100 with extradural hemorrhages of such extent that compression of the brain by blood was the chief cause of death. Pupillary changes, unilateral dilatation and fixation invariably occur with cerebral lesions and are usually associated with hemorrhage. Bilateral

widely dilated and fixed pupils indicate a rather grave prognosis. With unequal pupils, the dilated pupil is usually on the side of the lesion. The value of early eye ground examinations is greatly disputed at the present time. In the late cases, definite eye ground findings are noted.

TREATMENT OF INTRACRANIAL DAMAGE

The number of operations for acute intracranial injuries has decreased markedly since 1916. It is generally accepted that conservative treatment is not alone less dangerous but also more efficacious than operative treatment in the majority of cases, especially those without localizing signs.

Dandy¹ is of the opinion that "20% of all head injuries are lost in spite of all you do, 70% will recover if left strictly alone and 10% are saved only by a well timed and well directed operation." From our experience, we believe that 20% will die in spite of all you do, 60% will recover if left alone and 20% are saved by well directed treatment or operation.

Each patient admitted to our service suffering from a head injury is immediately put to bed. If the patient is in shock, no complete physical examination is made nor is the patient rushed to the x-ray department for radiographic study. The patient is treated for the primary shock in the manner described under concussion. The pupils are examined, temperature, pulse and respirations are taken every half hour. The reflexes are noted and we are on guard for any local signs. When the patient has reacted from the shock, then a more complete examination and careful study are attempted. The pupils are again examined and any inequality of the pupils is noted. The pulse rate and volume are carefully studied and recorded. The respirations are noted as to type and rapidity. The degree of consciousness is observed and we also note whether or not the patient has a tendency to lapse into unconsciousness. Muscular twitchings, and paralysis are looked for. The reflexes are carefully studied. A spinal tap is done and the spinal fluid pressure is noted. A small quantity of spinal fluid is allowed to flow into three test tubes, each tube being carefully studied to note the presence or absence of blood, for the spinal fluid to be classified as bloody, it must appear so in all three tubes. A pressure above 12 mm of mercury should be considered abnormal and enough fluid removed to bring the pressure down to normal or if the pressure should be greatly increased above normal, that increase should be relieved by about one half of the excess pressure. If equal to 18 mm it should be reduced to 15

mm by the first tap. Repeated spinal taps for both diagnostic and therapeutic reasons are of value though frowned upon by some investigators. The removal of the spinal fluid will reduce the pressure and also remove blood, which if allowed to organize either blocks the flow of spinal fluid or irritates the meninges. One must be certain that an extradural hemorrhage does not exist since in such injuries lowering of the spinal fluid pressure may start a secondary hemorrhage.

Recently, the intravenous administration of hypertonic solutions has been shown to decrease the spinal fluid pressure. Of the many solutions used, glucose has proven the safest, since it is non-toxic and apparently non-irritating. The administration of 50 cc to 75 cc of a 50% solution of glucose is followed by a gradual lessening in the spinal fluid pressure. This lowered pressure may not be sustained and the repeated administration of the same solution every six or eight hours may be necessary. Glucose not alone brings down the spinal fluid pressure but also has a splendid food value. Four to six ounces of a saturated solution of magnesium given per rectum will aid in sustaining the lowered spinal fluid pressure. The fluid intake must be limited so that the patient obtains at the most 1,000 cc in twenty-four hours. Rest, freedom from external stimuli, an ice cap to the head and attention to general hygiene are essential.

Absolute indications for operation are

- 1 Depressed bone with focal signs
- 2 Extradural hemorrhage with progressive or focal signs
- 3 Foreign bodies with focal signs
- 4 Abscess—intracranial

Every case of intracranial injury should remain under observation for at least one year with attention paid to all of the patient's complaints. The administration of various types of sedatives for headaches, irritability and nervousness is indicated. Penfield has suggested the injection of air via a method devised by him and described in an article entitled "Chronic Meningeal (Post-Traumatic) Headache. Its Specific Treatment by Lumbar Air Insufflation" which appeared in the December, 1927, issue of *Surgery, Gynecology and Obstetrics*.

In closing, may I be permitted to emphasize the necessity for conservatism in the treatment of head injuries and to warn against being stampeded into operative procedures. It is evident that the pendulum has swung far away from radicalism when one notes that in 1916 Sharp² reported 30 per cent of cases operated upon and in 1930 reported the percentage as 41%.

REPORT OF TWO HUNDRED AND EIGHTEEN COMPLETED CASES SEEN AT THE WESTCHESTER COUNTY PRENATAL CLINIC IN 1931

By MATTHIAS NICOLL, JR., M.D., AND EDWARD H. MARSH, M.D., WHITE PLAINS, N. Y.

From the Department of Health of Westchester County.

DURING the year 1931 there were seen at the prenatal clinic of the Westchester County Department of Health conducted at the White Plains Health Centre two hundred and fifty-five women who made a total of 1,256 clinic visits. Of these four were found not to be pregnant; for nine the subsequent history could not be learned (eight moved away and one could not be located). There were two hundred and eighteen completed cases of which records are available for study.

Of the two hundred and eighteen cases, one hundred and sixty-three were white and fifty-five colored; forty-nine were primiparæ and one hundred and sixty-nine multiparæ. Nineteen were gainfully employed, the majority of these being houseworkers. One hundred and seventy were delivered in hospital, twelve at home by physicians and thirty-two at home by midwives. There were two additional cases in which the midwife in attendance called a physician in consultation. There was one precipitate labor and one abortion in which there was no professional attendance until after the events occurred when physicians were called. Two hundred and one were natural de-

liveries, five were instrumental, six were prolonged or difficult, three were breech presentations, three were delivered by Cæsarian section. Twin birth occurred in two instances.

Time of Enrollment at Clinic

The greatest number of women enrolled at the clinic during the sixth month of gestation; the seventh and fifth month were closely grouped as second and third in frequency. Fifty-six per cent of the patients enrolled during these three months. During the first four months, more than one quarter registered, while practically one-third came for the first time during the last three months of pregnancy.

The following table shows for the white patients, colored patients and all patients the number enrolling for each month of gestation, the corresponding percentage and the cumulative percentage for each month. For all patients and white women the average was 5.6 and 5.5 months respectively; for the colored women the average was six months. The mode for the three groups was six months, six months and seven months respectively.

MONTH OF GESTATION DURING WHICH PATIENT ENROLLED AT CLINIC

Number of Clinic Visits Made

Excluding four patients who obviously should not be included in any analysis of the number of clinic visits made, the remaining two hundred and fourteen made a total of 1,093 clinic visits, an average of 5.1 per patient. The following table analyzes the clinic visits according to the month of gestation during which the mother entered the clinic.

treated regularly for syphilis but subsequently developed eclampsia which may have been the cause of the stillbirth rather than syphilis. The mother of the other stillbirth did not enter the clinic until the eighth month of gestation, too late for antisyphilitic treatment to be of any value to child. No explanation is offered for the fact that the mothers of three apparently normal infants did not enroll until the eighth month of pregnancy.

CLINIC VISITS BY MONTH OF ENROLLMENT

Month of Enrollment	Number Patients	Total Visits	Average No. Visits	Median	Maximum	Minimum
1	2	19	9.5	8	10	9
2	8	56	7	8	13	4*
3	20	144	7.3	8	13	2
4	27	166	6.1	6	13	2*
5	35	209	6	6	10	1
6	50	258	5.2	6	10	1*
7	36	132	3.6	3	8	1
8	29	96	3.3	3	7	1
9	7	13	1.8	2	3	1

*Excludes one woman who aborted shortly after first visit.

**Excludes two women who aborted shortly after first visit.

***Excludes one woman who transferred from clinic to private doctor after two clinic visits.

Syphilis

As a result of routine Wassermann tests, twelve cases of syphilis were found among the two hundred and eighteen patients. Not one of these presented any obvious manifestation of the disease. The serum of each of these patients caused complete or almost complete fixation of complement. Of the twelve, four were white women, eight colored; the incidence of syphilis was 2.5 per cent among the former and 15.5 per cent among the latter.

Seven apparently normal infants resulted from these twelve pregnancies. One child is alive but shortly after birth developed dermal manifestations of syphilis which have disappeared under specific treatment. Two other children were born alive but died; one of these was a seven months premature infant. There were two stillbirths in the group. The mother of one of the normal children gives a history of four previous miscarriages and three children who died in early infancy. This woman enrolled in the clinic during the second month of gestation, was given vigorous antisyphilitic therapy and had a normal child at term with a negative cord Wassermann test. One woman whose child died refused to cooperate and neglected treatment. The mother of the premature infant which died six weeks after birth had been vigorously treated for eighteen months. The mother of the syphilitic living child did not enroll in the clinic until the sixth month of gestation, evidently too late to prevent the disease in the offspring. The mother of one stillbirth enrolled early in her pregnancy, was

and could not possibly have had treatment sufficient to influence the results.

Complications of Pregnancy Other Than Syphilis

Albuminuria: Forty-eight (22½%) had albuminuria on one or more occasions; in thirty-eight this was transitory; in five cases the condition was slight but more or less constant; in three instances there was a moderate albuminuria fairly constantly; and two patients had a severe albuminuria throughout the later months of pregnancy.

Hypertension: More than 50 per cent (11) showed at one time or another hypertension (systolic blood pressure of 120 mm. or more). One hundred and five cases the blood pressure no time reached 120 systolic. The following table shows the range of systolic blood pressure in the two hundred and eighteen clinic patients.

There was but one case of eclampsia, and the blood pressure in this patient was never more

SYSTOLIC BLOOD PRESSURE—218 CLINIC PATIENTS

228.....	1
242.....	1
TOTAL	218

than 140 systolic. The woman with the blood pressure of 242 also suffered with severe cardiac disease and finally died in labor. Her case is described in detail later.

Only sixty-four women failed to have either albuminuria, hypertension or both. One hundred and fifty-four had one or both of these conditions.

Glycosuria: Two patients had slight glycosuria.

Cardiac Disease: Two patients definitely suffered from cardiac disease with decompensation, one with pulmonary edema. In addition in eleven others systolic murmurs were found; in one case there was a presystolic apical murmur and in one a diastolic murmur.

Defective Pelvis: Seven instances of justomino pelvis were discovered, there was one flat pelvis and one slightly funnel shaped pelvis.

Gynecological and Obstetrical Complications: There was one case of gonococcus infection; one patient gave a history of persistent bleeding dating from the fourth month of gestation; one presented an abnormal cervix uteri; there was one case of placenta prævia; one patient had an artificial vagina precluding a normal birth; one patient had eclampsia (mentioned above).

Miscellaneous Complications: Two patients had hyperthyroidism; one patient was persistently underweight and another overweight (253 lbs.).

Maternal Mortality

But one patient of the two hundred and eighty-eight died. This was the case of cardiac disease previously mentioned. She enrolled in the clinic during the seventh month of her fifteenth pregnancy. On account of her high blood pressure (242 systolic) on admission she was urged to enter the hospital immediately. After two days delay she went to the hospital, but in spite of definite improvement and contrary to advice she refused to remain. Five weeks later she came again to the clinic, this time suffering with extreme decompensation as evidenced by pulmonary edema. The patient was sent directly from the clinic to the hospital where with rest and proper supervision her condition improved immensely. However, after five days, in spite of all advice she insisted on going home. Two days later the woman went into labor, delivered an eight and one-half pound dead fetus, and a few hours later died.

Fetal and Infant Mortality

The two hundred and eighteen patients at the clinic were the mothers of two hundred and twenty potential infants (two twin pregnancies). The fetal and infant mortality however was high—twenty-three potential lives were lost on account of conditions associated with pregnancy. There were three abortions, fourteen stillbirths and six neonatal deaths.

Abortions: One mother who enrolled during the second month of gestation aborted at three months, cause undetermined; one aborted at about four months, cause unknown; and another, a woman forty-seven years of age, aborted also at the fourth month.

Stillbirths: Two of the mothers of stillborn infants enrolled during the third month of pregnancy. In one the fetus was carried to term but was dead when labor began; in the other the stillborn was a malformation. Three mothers enrolled during the fourth month. One delivered a stillborn macerated fetus at term; one had both syphilis and eclampsia but carried the fetus to term; one, a multipara, had a slightly contracted pelvis and after a prolonged (36-hour) labor was delivered instrumentally. The mother of a stillborn premature infant entered the clinic during the fifth month; the cause of the premature delivery is unknown. Three stillbirths resulted to mothers who enrolled during the sixth month; one of these was a prolonged labor in which a midwife was the attendant—a physician was ultimately called; one was a macerated twin fetus, the other twin being a normal infant; the third was due to cerebral compression as a result of instrumental delivery. This woman was a primipara with a contracted pelvis, who was permitted to remain in labor three days before she was sent to the hospital. Stillbirths resulted in two mothers who entered the clinic during the seventh month; one was the cardiac case who died (referred to previously), the other was a prolonged labor in which a midwife was the attendant, a physician being summoned later. Three stillbirths occurred to women who enrolled during the eighth month of gestation, one a difficult case of high forceps delivery, one a breech presentation with the cord about the neck and the third to a syphilitic mother.

Neonatal Deaths: One neonatal death was due to prematurity, cause unknown, the child living eight hours. Another seven months premature infant whose mother was syphilitic lived six weeks. A third premature child died of subdural hemorrhage and fetal atelectasis; this was a precipitate labor unattended by midwife or physician until after actual delivery; furthermore the mother was syphilitic and was ill with pneumonia at the time of delivery; the infant died on the day of birth. One child died an hour after birth; this also was a precipitate labor in which there was no professional attendance until after delivery. One child with a positive complement fixation for syphilis in the cord blood (mother a known syphilitic) failed to survive. One baby a malformation, died of convulsions two days after birth.

It will be noted in the accompanying table summarizing the causes of fetal and neonatal mortality that in many instances more than one factor is involved. For instance, although there are five

cases in which syphilis was a contributing factor, in one of them the mother had eclampsia and it was an instrumental delivery and in another the mother had pneumonia at the time of delivery

eclampsia and the stillbirth cannot be charged solely to instrumental delivery. The fourth was a high forceps delivery in the hospital necessitated by difficult labor.

FETAL AND NEONATAL MORTALITY—218 DELIVERIES

Case No.	Period of Gestation	Age of Infant	CAUSES OF DEATH									
			Un-known	Pre-mature	Syph'is	Mal-formation	Pro-longed Labor	Instru-mental Delivery	Mac-erated Fetus	Breech Delivery	Precip. Labor	Miscellaneous

and it was a precipitate labor. In such cases one can not attribute the fatality to any one individual cause.

Of the aforementioned twenty-three abortions, stillbirths or neonatal deaths, six were to primiparæ, seventeen to multiparæ; the relative frequency being about the same for both groups, 12.2 per cent in the former and 10.0 per cent in the latter. Seven were to colored mothers and sixteen to white mothers, the slight relative difference being insignificant

Instrumental and Operative Deliveries

In the whole group of two hundred and eighteen patients there were five instrumental deliveries and three Cæsarian operations. Only one of the infants delivered instrumentally lived, four were stillborn. One of these was to the primipara referred to previously under stillbirths, who was in labor seventy-two hours before being referred to the hospital. The second was to another woman with contracted pelvis but who had previously given birth to a normal child; her labor was prolonged (36 hours) and she was finally delivered with high forceps. The third was to the patient who had both syphilis and

Three women were delivered by Cæsarian operation. In all cases living children resulted and the mothers recovered without complication. The first case was a woman with an artificial vagina as a result of plastic surgery. She gave no history of this operation and her condition was discovered at the first examination at the clinic. The patient was instructed to go to the hospital immediately upon the appearance of the first sign of labor. The second was in a woman who had been pregnant twice. The first time the infant was stillborn after a very prolonged labor in which forceps was finally required; the second had been delivered by Cæsarian section and operation was therefore advised this time. The third case was in a woman who had had a threatened abortion at the third month. During the eighth month of gestation she had a sudden profuse vaginal hemorrhage without pain. A diagnosis of placenta prævia was made and the woman was sent into the hospital immediately. Cæsarian operation resulted in a three and one-half pound infant which is now nine months old.

Postpartum Examination

Postpartum examinations were made of one hundred women in the clinic. Of these fifty-

eight were found normal; forty-two were abnormal. Of the remaining one hundred and eighteen of which no record of postpartum examination is available, some who were delivered in Grasslands Hospital, undoubtedly had such examination made there.

Analysis of Clinic Results by Month of Gestation During Which Mother Enrolled in Clinic

The observations for the various months of gestation during which the mothers enrolled deal with too few cases in most of the groups to warrant comparisons or to permit conclusions to be drawn. However, the facts are given for what they may be worth.

1ST MONTH Two women enrolled during the first month of gestation. Both were primiparae and both delivered normal offspring naturally.

2ND MONTH	White..... 6	Primiparae.... 3
	Colored..... 3	Multiparae.... 6
	TOTAL..... 9	9

In this group, eight mothers delivered naturally eight normal infants. One abortion occurred at three months, cause unknown.

3RD MONTH	White..... 15	Primiparae.... 4
	Colored..... 5	Multiparae.... 16
	TOTAL..... 20	20

There was one instrumental delivery in this group, a multipara. Fifteen normal infants were born. There were two stillbirths; one premature child lived eight hours; one syphilitic baby (4 + cord Wassermann) died in early infancy; one malformation lived two days.

4TH MONTH	White..... 23	Primiparae.... 5
	Colored..... 6	Multiparae.... 24
	TOTAL..... 29	29

Twenty-three living babies resulted from this group. There was one abortion (mother forty-seven years old); there were four stillbirths; one precipitate labor occurred, the child living but one hour.

5TH MONTH	White..... 27	Primiparae.... 8
	Colored..... 8	Multiparae.... 27
	TOTAL..... 35	35

In this group there was one stillbirth, due to prematurity. One syphilitic mother gave birth to a seven-months' infant which lived six weeks; this woman had vigorous anti-syphilitic treatment for eighteen months. Two syphilitic mothers who were treated had apparently normal offspring.

6TH MONTH	White..... 44	Primiparae.... 10
	Colored..... 7	Multiparae.... 41
	TOTAL..... 51	51

There were three stillbirths in this group, two due to prolonged labor and one was a macerated fetus—one of a twin pregnancy—the second being a normal infant.

7TH MONTH	White..... 24	Primiparae.... 6
	Colored..... 12	Multiparae.... 30
	TOTAL..... 36	36

The maternal death previously described was from this group. Three stillbirths occurred, one child died the day of delivery.

8TH MONTH	White..... 20	Primiparae.... 8
	Colored..... 9	Multiparae.... 21
	TOTAL..... 29	29

Two stillbirths occurred in this group, or a breech presentation, the other to a syphilitic mother.

9TH MONTH	White..... 2	Primiparae.... 3
	Colored..... 5	Multiparae.... 4
	TOTAL..... 7	7

There were no obstetrical complications in this group and no infant deaths.

Conclusions

With few exceptions the foregoing data are insufficient in number to permit drawing mass deductions. Some facts however seem to be sufficiently striking to warrant emphasis.

1. Thirty-eight per cent of the white patients enrolled during the last three months of pregnancy; forty-seven per cent of the colored entered the clinic during this period. Greater effort needs to be made to secure earlier enrollment; particularly is this true for the colored race.

2. Too large a number of patients make too few clinic visits. Many of them, although enrolled during the earlier months of pregnancy came to the clinic but two or three times. The average number of visits is fairly adequate because a few women made a large number of visits.

3. The value of routine Wassermann tests is clearly demonstrated. Five and one-half per cent of the two hundred and eighteen patients were found to be syphilitic as a result of such examinations.

4. In at least one instance the value of anti-syphilitic treatment is clearly demonstrated.

5. Syphilis is much more prevalent among the colored patients. Fifteen and one-half per cent were found diseased, while only 2.5 per cent of the whites were affected.

6. The value of routine physical examination at regular intervals is demonstrated. Only 29.4 per cent of the patients failed to show albuminuria, hypertension or both at some time during pregnancy.

7. Vaginal examination should be made of all primiparae. Several cases of deformed pelvis were discovered and in one case of anomalous vagina not discovered until too late to assure child if such examination had not been at the clinic. This occurred. This

woman probably could have been saved and possibly the child if she had followed the advice given at the clinic and hospital.

9. The fetal and infant mortality was high—over ten per cent of the potential lives. A few of these might have been saved by prompt obstetric attention during delivery, but excluding these the proportion of fatalities would still be much higher than the average. No explanation is offered for this abnormal mortality other than the fact that the clinic clientele perhaps contains a larger proportion of the group which normally contribute most to fetal and infant mortality. The mortality was relatively as high among whites as colored.

10. Four of the five instrumental deliveries resulted fatally to the offspring. No criticism should be inferred by this statement. Forceps

delivery may well have seemed to be the lesser of evils. Indeed, in at least two instances earlier forceps delivery might possibly have given a different result.

11. In three Caesarian deliveries all mothers and infants survived in spite of the fact that one of the latter was premature and weighed but three and one-half pounds.

12. Less than fifty per cent of the mothers have postpartum examinations in the clinic.

We wish to acknowledge our indebtedness to Miss Marion McKinney, M.S., who assisted in compiling the data on which the foregoing report was based and also to give credit to Dr. William J. Mahar, clinician, and Miss Deborah Davis, R.N., for the actual work of the clinic and for the splendid records without which this study could not have been made.

SOME NOTES ON A HISTORY OF MEDICINE OF ONONDAGA COUNTY*

By LOUIS J. BRAGMAN, M.D., SYRACUSE, N.Y.

IN the opinion of William Welch, "it is well worth while to rescue the local annals of medicine in any part of the country." That this is particularly true of Onondaga County is attested to by Elsner, who remarked that "he who reads the history of the medical profession of central New York will agree that its fellows tenaciously swam on the upper stratum of the rising tide of medical progress." In a similar vein John Van Duyn has asked: "Do you believe that any county can show in its history of 1800 to 1845 a better lot of men than Onondaga in Day, Ball, Jones, Porter, Bartlett, Taylor, Sampson, and Needham?"

With the fast-moving progress of the present days, with the constant changes of time, and with the tendency ever to look forward, it would seem almost imperative that some effort be made to gather together in compact form such data as is still available for a History of Medicine of Onondaga County. The men who played an integral part in its development have almost entirely disappeared. Valuable records are fading, archives are gathering dust and are becoming extinct. A sense of loyalty, if nothing else, to those who came before us and laid the foundation, bids us feel impelled to erect some monument to their memories that we may know how it was we achieved our present status. It was with some such thought in mind that for the past few years I have attempted to assemble from various sources these fragments and bits of

historical data that in part shall be presented to you tonight, with the hope that, with the collaboration of others, a permanent record of the progress of medicine in our county may be obtained.

The following are some of the references of which I have made use: The Past and Present of Syracuse and Onondaga County, from prehistoric times to the beginning of 1908, by William M. Beauchamp; the History of Onondaga County, by Dwight H. Bruce; the Alumni Record of Syracuse University, by Smalley; the Physicians of the Village of Syracuse, by Didama; the Early Physicians of Onondaga County, by John Van Duyn; the History of Medicine in N. Y. State, by James J. Walsh; various manuscripts in the Onondaga County Historical Association Building, newspaper files, etc.

A comprehensive history of medicine of the county should comprise the following:

Biographical material of the physicians of the county, including photographs, if possible.

The history of the various local medical organizations, including a summary of the minutes of their meetings, papers read, activities, members, etc.

The history of the local medical institutions, including medical colleges, hospitals, sanitaria, publications, etc.

The history of public health measures, epidemics, etc.

Much of the material is on hand, easily available, merely awaiting collation. Gaps could undoubtedly be filled in with the assistance of many of the members of the county

* Read at the 125th Anniversary Meeting of the Onondaga Medical Society, Syracuse, N. Y., January 5, 1912

society, or by families of deceased members. In this manner a succinct volume could be compiled, which, brought up to date, would ensure the permanence of much valuable material that now is in danger of fading into the limbo of the past.

In this present contribution an attempt will be made merely to envisage the approach, first by giving a bird's eye view of the history of local medicine, and then by brief references to some of the outstanding achievements of former physicians. A card index of some eight hundred names has already been prepared as a start towards this work.

Some time after 1500, Beauchamp states, a group of Onondaga Indians settled in the northern part of the county. Champlain and his companions were known to have visited the locality in 1615. Erecting a log-trading house near the north of Onondaga Creek, Ephraim Webster in 1786 was the first white settler to dwell here, and in 1794 Onondaga County was definitely established.

The first doctor to arrive was David A. Holbrook. He was born in Sturbridge, Massachusetts in 1760, enlisted in the Army at Adams, Mass., in 1779, and is reputed to have visited Salina and other parts hereabouts previous to locating in Morehouse's Flats in the town of Dewitt in 1792. The next year he moved to Pompey Center, and around 1800 was practicing in Jamesville. He was one of the organizers of the County Medical Society in 1806, and died either in 1830 or 1832.

About 1794 a Doctor Pickard came to the town of Elbridge; at the same time Silas Park settled in Lafayette, moving to Pompey Hill around 1800, and dying in 1809. The first physician to practice in Syracuse was Zibia Swan, who arrived in 1807 and died the next year at the age of 41. He was succeeded by Jonathan Day who practiced in Syracuse from 1808 to his death in 1832.

In 1792 there were 31 inhabitants in the county. By 1836 eleven doctors had established in Syracuse. In 1845 the proportion of physicians to the population was 1—475 in Syracuse, and 1—1000 in the towns. Exclusive of Syracuse there were 92 doctors in the county at that time. In 1853 there were 38 doctors in Syracuse to a population of 25,000, a ratio of 1—660. In 1906 the ratio was 1—424. Today it is 1—522 in the city.

The Onondaga Medical Society was organized May 8, 1806. The county was then scarcely a dozen years removed from a forest uninhabited save by Indians. When the 22 members first met, there were only four medical colleges and three medical journals in the country. Syracuse was then known as Bogardus Corners; there were no physicians in

the low-lying towns in the north, the hills having attracted the first settlers. Some of the early men of eminence in the State, according to Alfred Mercer, were Bissel of Geneseo, Little of Avon, Ellwood, Backus, and Reed of Rochester. The stethoscope had appeared in Mercer's youth, a village doctor had advocated out-of-door living for consumptives, most men in practice were licentiates of county medical societies, and all were expert phlebotomists.

In 1808 the prize question before the County Society was: Does a Gonorrhea Virulenta ever become a confirmed Lues Venerea? And in 1826 the utility of examination by percussion and stethoscope in diagnosis and treatment of diseases of the chest was discussed. In 1851 the society discussed the question: Who performed the first surgical operation in Onondaga County? The honor was assigned to White of Whitesboro, of Oneida County, but it was also claimed that Bildad, Beach, and Hull, who had been studying with White had previously amputated a limb. In 1835 G. W. Richards reported a case of knife wound in the heart of a child; in 1832 a cholera meeting was held inasmuch as this dread disease had reached the shores of America. In 1840 Hoyt spoke on Phrenological Medicine, the first reference to psychiatry at a local medical meeting.

In 1847 the Syracuse Medical Association held its first meeting, becoming the City Medical Association in 1858, reorganizing in 1866, and changing to the Academy of Medicine in 1894. In 1849 the Homeopathic Medical Society of Central N. Y. was organized. A charter was obtained the same year for the establishment of an eclectic medical institute, which was then called the Syracuse Medical College. To 1855, 298 students had matriculated. Two years later the school passed out of existence. In 1850 an effort was made to start a medical school in the office of Hiram Hoyt, with the cooperation of Roger Pease, Henry Didama, and William Manlius Smith. In 1871 the County Society considered the possibility of the transference of the Geneva Medical College; in 1872 this took place. Walsh says that the history of the Syracuse Medical College, told completely, and in detail, is the history of the development of N. Y. State. It was the first college in the State, and the third in the country to adopt a three year course; and the laboratory of physiology, opened in 1896 under Gaylord Clark, was one of the first of its kind for the instruction of medical students.

That the physicians of Onondaga made their mark in American medicine is shown by the inclusion of a group of them in Kelly

and Budge's American Medical Biographies. Those mentioned in this classic volume are Backus, Buchanan, Didama, Elsner, Ford, Harris, Hyde, Jacobson, Lozier, Mercer, Plant, Shipman, Spencer, Van de Warker, Wilbur, and Wilder. A summary of the life of Elsner might serve as an index of how the biographical material of the men of our county can be handled:

Henry Leopold Elsner was born in Syracuse, N. Y., August 15, 1855. Studying medicine under his father, Leopold, for many years one of the best known herbalists in central New York; and under a brother, Simon, who was a physician, Henry subsequently graduated from the College of Physicians and Surgeons in New York, 1877. After a course of post-graduate instruction in Berlin and Vienna, he returned to Syracuse to start the practice of medicine in 1878. That year he joined the faculty of the Syracuse College of Medicine as instructor; in 1884 he was made lecturer in the Practice of Medicine; in 1886 he became professor of Clinical Medicine; in 1893 professor of the Science and Art of Medicine and Clinical Medicine; and in 1904 professor of Medicine.

He was at various times the president of the Syracuse Academy, the Onondaga Medical Society, the central New York Medical Association, and the New York State Medical Society. He was a member of the House of Delegates of the American Medical Association, and on the educational committee of that organization for several years. He was largely instrumental in bringing about the amalgamation of the New York State Medical Society and the New York State Medical Association. He was affiliated with the St. Joseph's Hospital, the Hospital of the Good Shepherd in Syracuse, and the State Hospital for Crippled Children at Tarrytown, N. Y.

Perhaps his greatest claim to lasting recognition rests as his skill as a prognostician. His "Prognosis" is a complete treatise on internal medicine, in 1200 pages, containing especial reference to prognosis. As Garrison, in his History of Medicine, says, Elsner "summed up the experience of a lifetime in his massive treatise on prognosis (1916), almost the only important work on the subject after Prosper Albinus (1601)." A bibliography of his writings reveals over 63 topics, ranging from a paper in 1885 on "Typhoid Fever As We See It In Central New York" to "The Prognosis of Chronic Myocardial Insufficiency," written in 1914. He died February 17, 1916 of cardio-vascular disease.

Brief mention might be made of some of the other outstanding physicians, as further proof that these records are worthy of being preserved. For

instance, Ely Van de Warker was among the pioneers in American gynecology, and was one of the founders of the American Gynecological Society. He is said to have performed over 2,000 laparotomies. He made a study of gynecological conditions at the Oneida Community in 1854 at the request of its leader, Noyes. He wrote on the mechanical treatment of versions and flexions of the uterus; discussed the treatment of extrauterine pregnancy by electricity; made a survey of the abandoned canals of the state of New York, for the Popular Science Monthly; and in 1903 wrote a book of 225 pages called "Woman's Unfitness for Higher Education," inspired perhaps by the inevitable cynicism engendered in the practice of gynecology. Nathan Jacobson, who studied abroad with Stricker, Billroth, and Hebra, wrote, according to my records, some 60 articles ranging from a case of mediastinal tumor in 1891 to perforated duodenal ulcer in 1913. He was known beyond the limits of the state as a surgeon of rare skill and medical learning, particularly in the diseases of the upper respiratory tract.

William Plant was the author of "A Succinct History of Medicine of the Last (the 18th) Century." Gregory Doyle, in 1880, read a paper on the dressing of Colles fracture and fractures of the leg, with plaster of paris splints made in sections. Two years later an English surgeon published an article on the same subject. Doyle invented many orthopedic devices, among which was a spiral spring rotator for automatic eversion and inversion in talipes. He was the first physician in Syracuse to use an automobile in making calls. Frederick Hyde, our first dean, has a long medical and surgical bibliography, among which is a paper called: "Some notes on 267 cases of dislocated hip, occurring in the State of New York." From 1850 to 1854 he operated with Miles Good-year, a private school in Cortland for anatomy and surgery, giving demonstrations and dissections. He wrote on malignant tumors of the abdomen, taxis in strangulated hernia, psoas or lumbar abscess, and trephination of the skull. P. J. Gibbons, practicing otolaryngology around 1880, invented an intranasal tube for the treatment of nasal stenosis, an adenotome for the removal of adenoids in the vault of the pharynx, and an apparatus for artificial respiration. He described a method for resuscitation from electric shocks which brought him world-wide acclaim. Charles Magee was reputed to have been the first in Syracuse, in the 1890's, to do a total hysterectomy, as well as the first to do intubation. Harvey Backus Wilbur was the first in America to attempt the education of the feeble-minded. He was the first medical director of the Syracuse State School, and wrote on "Aphasia," "The Relations of Speech and Language to Idiocy," and kindred topics. Gaylord Clark was the first in the coun-

try to devote himself exclusively to the teaching of physiology; in 1896 he wrote on "Equilibrium Fracture of the Ear." Alfred Mercer has a voluminous list of writings, and is notable particularly for his pioneer work in microscopy and photomicroscopy. In 1879 he wrote on the "Causes of Pus and Their Differential Characteristics"; and in 1881 published in the Transactions of the Pathological Society of London an article called "Tubercular Diseases of the Joints," the first practical microscopical contribution to this subject in England. Henry Darwin Didama wrote many articles of current interest and letters of travel in foreign lands under the pseudonym of Amos Cottle. John Wieting was a pioneer as a popular lecturer on the laws of physiology and

hygiene. Manville MacDonald invented a number of devices for the treatment of hernia. Robert Aberdein was the first in the county to perform a Cæsarian section. John Van Duyn, who has been professor of histology, anatomy, ophthalmology, otology, surgery, and the history of medicine, translated Wagner's "Manual of General Pathology" into English.

It would seem then, from these scant notes, that for scientific, historical, and sentimental reasons, some effort should be made to compile a History of Medicine of Onondaga County, dedicated, as it well might be, to those *Weelum Machures* who not so long ago guarded the health of the people living in the hills and valleys of Onondaga County.

THE TREATMENT OF TRAUMATIC RUPTURE OF THE POSTERIOR URETHRA

By JOHN H. POWERS, M.D., and DUDLEY W. SMITH, M.D., COOPERSTOWN, N. Y.

From the Department of Surgery of the Mary Imogene Bassett Hospital, Cooperstown, New York.
Read before the Otsego County Medical Society, June 8, 1932.

TRAUMATIC rupture of the posterior urethra presents one of the most difficult therapeutic problems in urological surgery. Many methods of conservative and radical operative treatment have been advocated from time to time but the best opinions regarding the proper management of such cases are at considerable variance with one another. The purpose of this report is not to discuss these methods, but to record three simple procedures which were found useful in the treatment of two patients with this condition.

In each case, the injury was the result of an automobile accident and was complicated by fractures of the pubis. One patient was a boy, nine years old; the other was a man, sixty-one years of age. Both patients were brought to the hospital soon after the injury was received. The diagnosis of rupture of the posterior urethra was based on the patient's inability to void, gradual distension of the bladder, unsuccessful attempts to pass a catheter followed by the appearance of a few drops of fresh blood at the meatus, and ecchymosis of the perineum, upper portion of the scrotum, and base of the penis. Confirmation of the pelvic fracture was obtained by roentgenological examination.

Suprapubic cystotomy was performed as soon as the diagnosis had been made. In the first case this was followed immediately by external perineal urethrotomy and repair of the floor of the ruptured urethra over an inlying catheter. The roof of the urethra was so severely lacerated that the edges could not be brought together. In the second case, it was not considered advisable to explore the urethra immediately because the pa-

tient was in a mild degree of traumatic shock. Twelve days later a soft rubber catheter on a stillette was passed into the bladder without difficulty and urethral repair was not attempted.

The subsequent treatment of these two patients was facilitated and simplified by the following procedures:

1. *Use of Inlying Urethral Catheter as a Splint Only, with Continuous Drainage of the Bladder by a Suprapubic Tube.*

Drainage of the bladder was maintained constantly by a suprapubic mushroom catheter.

The tip of the urethral catheter, instead of remaining within the bladder, was brought out through the suprapubic wound and fixed to the anterior abdominal wall by passing several sutures of silkworm gut through the catheter and around a sterile, wooden tongue-depressor. The tongue-depressor was allowed to lie on the abdominal wall just above the pubis, at right angles to the incision and superficial to the dressings immediately overlying the wound (Figure 1). This was covered with more sterile gauze and all was held in place firmly with straps of adhesive plaster.

This very simple scheme was devised to prevent patients from withdrawing the urethral catheter at inopportune moments, and is especially applicable to children whose conduct is not always easy to control (Case 1).

It is believed by the writers that such an inlying urethral catheter acts as a splint around which the lacerated or repaired urethra heals more readily than when no attempt at immobilization is employed.

The bladder may be irrigated through the su-

prapubic tube and the splinting catheter left in the urethra for as long as desired. The necessity for its frequent removal and the dangers of introducing a new catheter through a recently repaired urethra are thereby obviated.

FIGURE 1

Drainage of the bladder is maintained by the suprapubic mushroom catheter.

The inlying urethral catheter acts as a splint and not as an outlet for urine. The upper end is brought out through the bladder to the abdominal wall and fixed to a sterile tongue-depressor by several sutures of silkworm gut. (The tongue-depressor should lie at right angles to the suprapubic wound instead of parallel to it as shown in this diagram.)

adequate size by followers, the filiform is permanently removed and subsequent dilatations are carried out with sounds.

FIGURE 2

The inlying filiform is introduced either through the urethral splinting catheter before this instrument is removed or by suprapubic cystostomy and retrograde passage of a ureteral catheter through the internal orifice past the stricture and out through the meatus; the filiform may be attached to the lower end of this instrument and drawn back through the urethra and bladder. When not in use, sterile clamps are attached to each end. Followers may be screwed to the lower end and the urethral stricture dilated as indicated.

2. Use of Inlying Filiform as a Guide to the Passage of Metal Followers.

Utilization of a silk thread as a seton for preserving the integrity of the lumen of a lacerated or strictured urethra has been described by McWhorter.¹ The authors believe that a filiform, to which metal followers may be attached, is a much more satisfactory instrument for this purpose.

In Case 1 the filiform was introduced through the inlying urethral catheter from below, the tip was passed out through the suprapubic wound and the catheter was withdrawn. Sterile clamps were attached to each end and the instrument was left in place.

In Case 2 the filiform was introduced by the method described in the next section.

At intervals of three to seven days the patients were taken to the operating room, the clamps were removed, and the urethra was easily and gradually dilated to proper size by attaching metal followers to the inlying filiform-guide (Figure 2).

The filiform was then removed, the mushroom catheter was withdrawn and the suprapubic wound was allowed to heal.

No urethral reaction occurs around such an inlying guide which is easily held in place, and may be left in the urethra as long as is desired. When the stricture of the urethra has been dilated to

3. Suprapubic Cystoscopy and Retrograde Instrumentation of the Urethra.

During the interval after withdrawal of the urethral splinting catheter of the patient described in Case 2, such a dense stricture formed at the site of injury that neither sounds nor filiforms could be passed from below.

Consequently, cystoscopy was performed through the suprapubic sinus (after removing the mushroom catheter) and by this maneuver it was possible to pass a ureteral catheter down through the internal urethral orifice, past the stricture, and out through the meatus below. The tip of a filiform was then tied to the lower end of the ureteral catheter and drawn up through the urethra and out through the wound to the anterior abdominal wall.

Furthermore, suprapubic cystoscopy was found to be a valuable aid in determining the success of subsequent dilatations of the urethra with sounds. By looking into the bladder from above and passing a sound simultaneously through the urethra from below, it was possible to tell with great accuracy whether the tip of the instrument emerged through the internal orifice or whether it had been diverted by a false passage into the perivesical tissues around the neck and floor of the bladder.

Report of Cases

Case 1. V. D.—a white boy, aged nine, entered the hospital June 5, 1931, complaining of severe pain in the back, left lower quadrant of the abdomen, and left hip, following an automobile accident.

Past History. Irrelevant.

Present Illness. The patient was struck on the left hip and in the left flank by a passing car and thrown to the ground. He entered the hospital fifteen minutes later.

Physical Examination. There were numerous superficial abrasions of both arms, thighs, and legs, and one deep abrasive burn of the left flank just above the crest of the ilium. Severe pain was induced by motion of both hips and by compression of the iliac crests. There was marked tenderness in the perineum. The pulse rate was 100, and the blood pressure was systolic, 90; diastolic, 60.

Roentgenological Examination. X-ray of the pelvis disclosed a fracture of both rami of the left pubis with medial and downward displacement of the separated fragment.

Clinical Course. The patient was unable to void and three hours after admission began to complain of distension of the bladder. Ecchymosis appeared in the perineum and along the dorsal aspect of the base of the penis. The bladder could be percussed half way to the umbilicus. Unsuccessful catheterization was attempted with soft rubber and metal catheters. Upon withdrawal of the instrument each attempt was followed by the appearance of a few drops of bright red blood at the meatus.

Preoperative Diagnosis.

Multiple superficial abrasions.

Fractures of the left pubis.

Traumatic rupture of the posterior urethra.

Operation. Suprapubic cystotomy, external perineal urethrotomy, partial suture of lacerated posterior urethra over an inlying rubber catheter. Five hours after admission the patient was taken to the operating room and suprapubic cystotomy was performed under general anesthesia. The space of Retzius and the perivesical tissues around the neck of the bladder were heavily infiltrated with blood. The bladder was not ruptured.

The patient was then placed in lithotomy position and the posterior urethra was exposed by a v-shaped incision with the apex anterior. A sound was introduced into the urethra and, in the region of the membranous portion, a cavity containing liquid and clotted blood was opened. The distal end of the urethra was severely lacerated and a complete transverse rupture was found. The proximal end could not be located until a sound had been introduced in retrograde fashion in the posterior urethra through the bladder. The proximal end had retracted for some distance and the roof had been entirely destroyed for at least three-quarters of an inch. After excising much of the lacerated tissue, it was possible to suture the floor of the urethra over an inlying rubber catheter. The perineal wound was closed around a rubber tissue drain and the bladder was placed on constant drainage through a suprapubic mushroom catheter.

Postoperative Course. On the ninth postoperative day the patient pulled out the inlying catheter in spite of the fact that it had been sutured to the prepuce with silk. An attempt to pass a sound into the bladder through the urethra one month after operation was unsuccessful. A low grade osteomyelitis occurred in the separated fragment of the pubis which was removed at the end of two months.

Subsequent attempts to pass sounds into the bladder through the urethra were all unsuccessful because of an obstruction at the site of rupture. Consequently, a second urethrotomy and plastic repair of the strictured urethra were performed four and one-half months after

admission. The membranous urethra consisted of dense scar tissue which, when exposed, would not admit a sound or a filiform. Retrograde sounding through the bladder was likewise unsuccessful. The dense scarred portion of urethra was completely excised, an inlying catheter was placed through the anterior urethra, across this gap, through the proximal urethral segment and brought out through the bladder to the abdominal wall where the tip was firmly fixed in position by ligating it to a sterile tongue-depressor (Figure 1). Drainage of the bladder was reestablished by a suprapubic mushroom catheter. No irritation or discharge occurred around the inlying catheter which acted purely as a urethral splint.

Two weeks later a filiform was introduced through this catheter from below to the abdominal wound and the catheter was removed. At intervals of three to five days metal followers were attached to the filiform and the caliber of the urethra was dilated gradually to 23F. The mushroom catheter and inlying filiform were then removed. The suprapubic wound closed rapidly and the patient was able to void spontaneously without difficulty. Dilatation with sounds was continued at intervals until the patient's discharge on December 24, 1931.

Subsequent Note. May 17, 1932. The boy voids normally without difficulty. The abdominal wound is firmly healed and the urethra admits a 20F sound with ease.

Case 2. C. H.—a white man, aged sixty-one, was admitted to the hospital by ambulance, September 27, 1931, complaining of pain over the pubis, in the rectum, in the left gluteal region, and of inability to use the left leg.

Past History. Urinary frequency, nocturia, and difficulty in voiding had been present during the previous one and one-half years.

Present Illness. The patient was involved in an automobile accident in which he was thrown violently forward, and struck his left hip against an irresistible object. The injury was followed immediately by severe pain in the regions described above and by complete disability of the left leg.

Physical Examination. The mucous membranes were pale and the patient was obviously in pain. Tenderness and ecchymosis were present about the left hip, and in the perineum. Pain was induced by passive motion of the left thigh, and by pressure over the symphysis pubis. The prostate was moderately enlarged. The pulse rate was 60 and the blood pressure was systolic, 100; diastolic, 60.

Roentgenological Examination. X-ray of the pelvis revealed a fracture of the descending ramus of the left pubis.

Clinical Course. During the first two hours after admission, the blood pressure gradually fell to systolic, 60; diastolic, 50. The pulse was of poor quality, and the patient was in rather severe shock. After the administration of 1,000 c.c. of ten per cent solution of glucose intravenously and 1,000 c.c. of normal saline hypodermically, the systolic blood pressure rose to 100 and the diastolic to 70. During this interval the patient began to have an urgent desire to void but was unable to do so. Attempts to catheterize the bladder with rubber, silk-woven, and metal instruments were unsuccessful. Each effort was followed by the appearance of several drops of fresh blood at the meatus.

Preoperative Diagnosis.

Fracture of left pubis.

Traumatic rupture of the posterior urethra.

Benign hypertrophy of the prostate.

Traumatic shock.

Operation. Suprapubic cystotomy. Eight hours after admission to the hospital, the patient was taken to the operating room, and suprapubic cystotomy was performed under local anesthesia. The space of Retzius and the perivesical tissues around the neck of the bladder were heavily infiltrated with blood. It was not possible to pass a sound through the urethra, either from

below or in retrograde fashion through the internal orifice. Exploration of the urethra through the perineum was not considered advisable because of the patient's poor general condition, and the bladder was drained by a suprapubic mushroom catheter.

Postoperative Course. The following day the blood pressure was normal. Four days later the patient developed a transient urinary infection which was controlled by the administration of sodium acid phosphate and urotropin, with large amounts of fluid. On the twelfth postoperative day, it was possible to pass sounds through the urethra into the bladder without difficulty. An 18F soft rubber catheter was introduced on a metal stillette, the tip of the catheter was brought out through the suprapubic wound and fixed to the abdominal wall by several sutures of silkworm gut passed over a sterile tongue-depressor. Intravesical palpation of the prostate at that time disclosed moderate hypertrophy of the median lobe. No reaction occurred around the inlying urethral catheter which functioned merely as a urethral splint, and not as an outlet for urine.

Three weeks later this catheter was removed, the suprapubic wound was enlarged under spinal anesthesia and the hypertrophied median lobe of the prostate was excised with a punch. The urethral catheter was not replaced, and drainage of the bladder was maintained above.

After an interval of ten days, attempts were made to pass sounds into the bladder through the urethra, but all were unsuccessful because of an obstruction in the posterior urethra. Similar efforts with filiforms met with the same result. A urethroscope was passed to the point of obstruction, and a dense stricture was seen in the region of the membranous portion. The mushroom catheter was removed, a cystoscope was introduced into the bladder through the suprapubic wound and a urethral catheter was passed through the internal urethral orifice past the point of stricture and out through the meatus. A filiform was attached to the distal end and drawn back through the urethra and bladder to the abdominal wound. Metal clamps were attached to each end of the filiform and the instrument was left in place.

During the subsequent two weeks metal followers were attached to the inlying filiform and the urethra was dilated at intervals of five to seven days. The filiform was then removed and further dilatations with sounds were continued to 30F. The accuracy of these procedures was verified by simultaneous suprapubic cystoscopy and observation of the tip of the sound in the internal urethral orifice.

Drainage of the bladder from above was then discontinued, the suprapubic wound was allowed to heal, and the patient was discharged December 12, 1931.

Subsequent Note. Recent report from the patient states that he is in good physical condition and is urinating freely.

Comment and Conclusion

The authors believe that the period of hospitalization of these two patients could have been shortened materially had the procedures which are described above been instituted early in the postoperative convalescence.

The following regime is suggested for the treatment of patients with traumatic rupture of the posterior urethra.

Immediately after the diagnosis is made, suprapubic cystostomy should be performed. If a catheter cannot be passed through the urethra either directly or in retrograde manner, and the general condition is suitable, perineal urethrotomy and repair of the ruptured urethra should be performed over an inlying soft rubber catheter. The tip of this instrument should be fixed to the abdominal wall and act only as a urethral splint, while drainage of the bladder is secured by the suprapubic method. At the end of twelve to fourteen days, a filiform should be passed through the urethral catheter, which is then withdrawn. The filiform is left in place and dilatations of the urethra are carried out at intervals of three to seven days by attaching metal followers to this instrument. When a satisfactory caliber of the urethra has been obtained, the mushroom catheter is removed and the suprapubic wound is allowed to heal. This may be hastened by draining the bladder temporarily with an inlying urethral catheter for a few days. Subsequent dilatations should be performed at gradually increasing intervals before the patient is finally discharged.

REPORT ON THE OCCURRENCE OF GONOCOCCIC VAGINITIS IN THE NEW BORN

By E. J. WYNKOOP, M.D., and WINTHROP PENNOCK, M.D., SYRACUSE, N. Y.

From the Department of Pediatrics, College of Medicine, Syracuse University, and the Hazard Memorial Laboratory, Syracuse Memorial Hospital.

AT the 1923 meeting of this Society, a preliminary report on the occurrence of Gonococcic Vaginitis in the New Born was read, and subsequently published in the New York State Journal of Medicine, October, 1923.¹

The report was drawn from work which consisted of the routine examination of vaginal smears on all female infants born in the Syracuse Memorial Hospital. 163 cases were observed. The method of study was as follows:—Smears were taken with a platinum wire loop from the vestibulum vaginae on the 1st, 4th, and 13th days. These smears were examined for gram negative intracellular diplococci and the presence or absence of polymorphonuclear leukocytes, and the form and staining characteristics of the prevailing types of bacteria. No gram negative intracellular diplococci were found in any smears examined in this series of 163 cases.

In November, 1926, Dr. E. J. Wynkoop and Dr. Edgar O. Boggs reported² 435 additional cases studied in the same manner and with the use of the same technique as in the preliminary report; i.e., the routine examination of vaginal smears in the New Born taken on the 1st, 4th and 13th days. No smear showed gram negative intracellular diplococci in the 435 cases examined. Four cases of gonococcic ophthalmia of the New Born were discovered among the 435 cases examined, none of which developed gonococcic vaginitis.

We have studied 552 additional cases, making a total of 1150. In this third series as in the 1st and 2nd series previously reported, no smear showed gram negative intracellular diplococci. 12 cases of gonococcic ophthalmia in the New Born were discovered in the 552 cases studied.

The following is a brief summary of the total number of cases examined.

1. Number of cases—1150. Days on which smears were taken—1st, 4th and 13th.
2. Number of cases showing no polymor-

phonuclear leukocytes at any of three examinations—460 or 40%.

3. Number of cases showing polymorphonuclear leukocytes in the 1st day smears—195 or 17%.

4. Number of cases showing polymorphonuclear leukocytes in the 4th day smears—241 or 21%.

5. Number of cases showing polymorphonuclear leukocytes in the 13th day smears—494 or 43%.

6. Number of vaginal smears showing gram negative intracellular diplococci—none.

7. Number of cases showing gonococcic ophthalmia in the New Born—19 or 1.6%.

Several varieties of bacteria were found. Gram positive cocci and gram positive and gram negative bacilli were the most frequent forms. The smears containing no polymorphonuclear leukocytes showed fewest bacteria. Many such contained no, or very few bacteria. On the other hand, smears were occasionally found which contained rather large numbers of organisms in the absence of polymorphonuclear leukocytes. The type of bacteria, as a general rule, seemed to determine the presence or absence of polymorphonuclear leukocytes. The gram positive cocci were associated in a considerable number of cases with large numbers of polymorphonuclear leukocytes. Gram positive or gram negative bacilli usually predominated in cases showing no, or but few polymorphonuclear leukocytes. In but a few cases were numerous pus cells found in the absence of bacteria.

CONCLUSIONS

1. The occurrence of gonococcic vaginitis in the New Born is extremely rare.
2. The presence of polymorphonuclear leukocytes in the vaginal secretions of the New Born is of little clinical significance.
3. The mere presence of polymorphonuclear leukocytes in the vaginal secretions should not be taken as evidence of gonococcic vaginal infection of the New Born.

A CASE OF MONOCYTOID MYELOBLASTIC LEUKEMIA*

By CARL REICH, M.D., NEW YORK, N. Y.

RESCHAD and Schilling-Torgau¹ described the first case of monocytic leukemia in 1913. Since then 26 other cases have been reported. These were recently reviewed by Dameshek² who added two additional cases. Many hematologists believe that monocytic leukemia is a separate entity and that the monocytes are derived from reticulo-endothelial cells. Other authorities, notably Naegeli³, state quite definitely that there is no such thing as a true monocytic leukemia, and that it is only a variety of myeloblastic leukemia and will turn into the latter type if the patient lives long enough. This latter school also believes that monocytes are derived from myeloblasts.

The following case is of interest in that it presents a patient who became ill with what appeared to be a monocytic leukemia and then ended up with a myeloblastic leukemia.

Case History—The patient was a young German male, 33 years old, a painter by trade. He was admitted to the hospital on 7/11/31 with the complaint of sore throat, 3 weeks in duration. He had always been well and the onset of his illness was acute, with fever, headache and swelling of the glands of the right side of the neck. His voice became hoarse and he had difficulty in swallowing. He was treated with argyrol and gargles, but became progressively worse and hospitalization was considered necessary.

On admission his temperature was 103, pulse 100 and respiration 20. He looked quite ill and complained of severe pain in his throat. His tongue was heavily coated and the gums were swollen and inflamed, with marked pyorrheal changes around the base of the teeth. The tonsils were red and boggy and there was a large swelling around the right tonsil, extending to the soft palate and pushing the uvula to the left. The glands at the angle of the jaw on the right side were enlarged and a few pea sized glands were palpable in the cervical region on both sides. The physical examination was otherwise essentially negative and a diagnosis of acute tonsillitis with right peritonsillar abscess was made. The

supposed abscess was incised but no pus was obtained. Culture from the incision showed mic. catarrhalis, non hemolytic streptococcus, pneumococcus and influenza bacillus. The blood count 7/22 was Hb. 54%, R.B.C. 2,700,000, W. B. C. 52,300. Neutrophils 14%, Lymphocytes 25%, Monocytes 61%. The blood Wassermann test was negative. The throat condition began to improve and the temperature slowly came down. On 7/24, seven days after admission, his blood count was Hb. 44%, R.B.C. 1,900,000, W.B.C. 36,200. Neutrophils 7%, Lymphocytes 24%, Monocytes 69%. His temperature ranged around 101 and the spleen, axillary and inguinal lymph nodes were definitely enlarged. During the next month the patient ran a low grade septic temperature, going up as high as 101 in the afternoon. Repeated blood cultures were sterile. The urine showed albumin and casts. The anemia became more pronounced and two 500 c.c. blood transfusions were given with no improvement. The blood picture slowly changed and on 7/30 it was Hb. 30%, R.B.C. 1,400,000, W.B.C. 8,100. Neutrophils 14%, Lymphocytes 70%, Monocytes 14%, Myeloblasts 2%. The myeloblasts gradually increased in number and the patient had hemorrhages from the gums, a hematoma of the eyelid and retinal hemorrhages. The count on 8/21, four weeks after admission, was Hb. 20%, R.B.C. 1,000,000, W.B.C. 19,900. Neutrophils 5%, Lymphocytes 26%, Monocytes 19%, Myeloblasts 50%. The patient became rapidly worse and expired, 8/23. Autopsy was refused.

Discussion—This case may be explained in two different ways. It is possible that the patient first ran an acute angina with a concomitant monocytoid reaction. Following this he developed an acute myeloblastic leukemia. On the other hand, the high total white count and the anemia noticed at the onset of the illness speak against it being a benign process at that time. This would lead to the second explanation which is that it was a case of monocytoid myeloblastic leukemia. This type of leukemia begins with an increase in monocytes and then ends as a myeloblastic leukemia.

QUESTIONNAIRES

Every medical editor is often asked to promote a questionnaire in order that some one may obtain what is called "the opinion of the medical profession" regarding some point. The questionnaire is a statistical study whose value depends on at least two unknown quantities:

1. The exactness of the question that is asked.
2. The qualifications of the answerers.

A physician may be asked, "Do you prescribe Smith's rheumatic pills?" He can answer it truthfully if he has tried them only once.

The next question may be, "What results did you get?" The answer might truthfully be, "The patient was well on the next day." The interpretation of such statistics as these is that Smith's rheumatic pills are one hundred per cent efficient;

but in reality the first question is inexact and meaningless, and any doctor that answers it thereby demonstrates his incapacity to give a thoughtful opinion.

Object of the Questionnaire: A questionnaire is used for either one of these objects:

1. A record of scientific observations.
2. A basis for publicity.

The Scientific Questionnaire: Medical societies and the editors of their journals are always ready to promote scientific observations, and to give publicity to the results. An example of valuable study conducted by means of a questionnaire is that of student medical service in the colleges of New York State, reported in this Journal of November 1, 1930, page 1283. This particular questionnaire dealt with facts rather than opinions; and yet the facts reflected widely varying opinions and attitudes of the governing authorities of the colleges in regard to the health service which they provide for their students. The report is of value to the colleges and their students, to the parents about to choose a college, and to physicians who are consulted regarding the health of students.

Publicity: In contrast with the scientific study of a problem is the questionnaire conducted for publicity ends. This publicity is of two forms:

1. Propaganda.
2. Advertising.

Propaganda: A propaganda is any systematic scheme for propagating an opinion or course of action. It is like the plea of a lawyer employed to promote one side of a case. The field of public health is occupied by many organizations whose strength is their ideals backed up by financial endowments. These organizations make free use of the questionnaire in support of their cause, often to the annoyance of family doctors who

wish that both sides of a problem shall be presented impartially.

The officers and editors of medical organizations are cold in their attitude toward all forms of propaganda because they dare not say that any form of treatment is a sure cure for any ill, either personal or civic. Physicians are therefore not responsive to a questionnaire whose object is to support a cause or an ideal.

Advertising: The questionnaire is abused when it is used for a selfish end, especially one that is financial. Medical journals are confronted with the economic problem of balancing their expenses for salaries, printing, and postage, against receipts from subscriptions and advertisements. The NEW YORK STATE JOURNAL OF MEDICINE conducts its advertising department on the theory that it serves both the medical profession and the public by announcements regarding standard medical wares; and at the same time its service to manufacturers and dealers is worthy of the same kind of financial remuneration that a family doctor receives from his patient. Medical service comes first, and financial considerations are secondary.

Medical advertisements are often handled as a subdivision of some advertising agency which uses the methods of supersalesmanship employed in selling automobiles, and cosmetics, and hats. The questionnaire is a favorite device in which the cooperation of medical editors is often asked. The reply of the editors is always that of the conscientious family doctor who refuses to lend his professional support to any purely financial scheme of a patient. This point of view is generally accepted by manufacturers and dealers in medical wares. The advertising agencies also appreciate the attitude of the physician when the principles of the medical profession are explained to them.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Automobile Accidents:—This Journal of October, 1907 has an editorial on physical fitness which suggests a physical examination for drivers of locomotives and automobiles. The part referring to automobiles is as follows:

"The automobile rushes through the streets and country in the hands of any one who lays himself to the task. The number of accidents is appalling. The driver may be half blind, deaf, or parietic—there is no restriction. The large number of fatalities are all in the day's work, so long as we do not know the parties involved; but still we may be the next victims, and then it becomes

a different matter. No person should be permitted to run an automobile faster than four miles an hour within the town limits who has not been subjected to a physical examination and determined physically fit and free from disease which does or might suddenly incapacitate him. A medical examination should be necessary for a license, and the license should be good for one year. This need not be burdensome or expensive, and it would surely be for the public good. Our anti-paternalist might object to such an ordinance, but after he is run into by a cross-eyed parietic, he will be convinced, if he survive."

MEDICAL PROGRESS

Early Diagnosis and Treatment of Pregnancy Toxemia.—Norman White divides the toxemias of pregnancy into two main groups: (1) albuminuric toxemia, pre-eclampsia, and eclampsia; and (2) hyperemesis. Albuminuric toxemia occurs usually in from 3 to 5 per cent. of previously healthy women. The dangers of this form of toxemia are: (1) eclampsia; (2) permanent renal damage; (3) death of the fetus. The writer has examined the case sheets of 18 recent cases of eclampsia and found that in 8 cases symptoms of toxemia began one month or more, and in 7 cases one or two weeks before the onset of convulsions; in 3 cases the onset was rapid, the patient being probably normal two or three days before the convulsions occurred. Fifteen of the cases therefore could have been diagnosed by efficient antenatal supervision, and in the other three the fits might possibly have been prevented if the patient had come for examination when she began to feel ill and treatment had immediately been instituted. In toxemia, edema is the most important early symptom, being absent only when the onset of toxemia is fulminant. It starts in the feet and legs and may then be regarded as due to pressure by the enlarging uterus, but it should be taken as a warning to look for albuminuria and a rise of blood pressure. Generalized edema, shown by swelling of the face and hands, is a more definite sign of toxemia. The most important type of edema is that which gradually spreads up the thighs and on to the abdominal wall. Headache is a later symptom, preceding the development of albuminuria and the rise of blood pressure by not more than about two weeks. Visual disturbances are also a late sign. Partial or complete blindness commonly precedes the first convulsion by not more than an hour or two. Other signs calling for immediate treatment are the rapid onset of severe headache and epigastric pain. A rise of blood pressure is the most important symptom of toxemia in the pregnant woman, and therefore routine blood pressure estimations should be made repeatedly throughout pregnancy. According to F. J. Browne these should be made every month till the thirtieth week, then fortnightly till the thirty-sixth week, and weekly after that till delivery. Any rise in blood pressure, in a woman not over 35 years, to more than 140 mm. should be regarded as probably toxic, and a rise to 160 mm. or more is an urgent indication for treatment. Albuminuria occasionally occurs as the first sign and rapidly increases in amount in the pre-eclamptic state. Antepartum hemorrhage is an occasional consequence of toxemia, usually however associated with extensive placental infarction. As a

rule a toxemia which leads to antepartum hemorrhage does not cause eclampsia. The most important point in all methods of treatment is absolute rest in bed, and in cases of mild toxemia little else may be called for. The diet may be restricted (1) to give rest to the kidney, (2) to prevent the production of a hypothetical toxin in the alimentary canal, (3) to decrease the production of acid and increase that of alkali in the body, and (4) to decrease the ingestion of salts. The patient should drink large quantities of plain water, lemonade, or barley water, lemonade being the best. Elimination of the toxin is to be encouraged by this ingestion of a large amount of water, inducing diuresis or diaphoresis, and purgation by magnesium or sodium sulphate. If the toxemia is not overcome or markedly reduced by the end of a fortnight the pregnancy should be terminated.

Hyperemesis gravidarum is rare as compared with toxemia. The sufferer should be treated by isolation and reduced diet. In definitely toxic cases one must forbid all feeding by the mouth and give saline enemata or rectal drip with 5 per cent. glucose added. Bromides may be added to the enemata. If the urinary output remains small and the patient's condition does not improve, therapeutic abortion is indicated.—*The Practitioner*, September, 1932.

Blockade Theory of Polyp Formation.—John L. Jenkins adds another and a plausible theory to those at present accounting for the origin of nasal polyps. This type of polyp, he says, is always preceded by more or less marked chronic inflammation. The polyp is an accumulation of intracellular fluid dammed up by an infiltration of lymphocytes producing a blockade of intercellular spaces. Now if this blockade of lymphatic elements is lifted the accumulated fluid will be absorbed, with disappearance of the polyp. Roentgen rays or radium in proper dosage will dissolve out the lymphatic elements, but if the chronic inflammation continues the round cell infiltration will recur and the polyp will reappear. Occasionally the polyp itself by its weight or its pressure may be a factor in keeping up the chronic inflammation, and so a sort of vicious circle results. Examination of an old polyp, which has existed for months or years, gives no clue to the nature of its formation, by reason of the tissue and chemical changes produced by time. But the author has arrived at his conclusions as to the constitution of newly formed polyps from a chemical and radiographic study before these changes have occurred.—*The Laryngoscope*, September, 1932.

The Relations between Paroxysmal Tachycardia and Lesions of the Myocardium.—Ralph H. Major and H. R. Wahl, writing in the *Archives des maladies du cœur* of August, 1932, say that a recent study of 4 cases of paroxysmal tachycardia, 2 of which were of auricular and 2 of ventricular origin, revealed upon microscopic examination the presence of grave lesions of the myocardium, which might have been completely overlooked in a superficial examination. In every case the patient died during the course of an attack. Histological examination of the myocardium revealed in Case 1 numerous foci of inflammation, with lesions more marked in the ventricles than in the auricles, degeneration of the myocardium with muscle fibers replaced by fibrous tissue; in Case 2, both acute and chronic myocarditis, more marked in the auricles; in Case 3, marked increase in size of the heart muscle and degeneration of muscle fibers, shown in fragmentation and segmentation of these; in Case 4, chronic interstitial myocarditis, segmentation of muscle fibers, with infiltration of round cells; numbers of disseminated islands of sclerosis and hyaline degeneration, with foci of necrosis in the muscle fibers. The ages of the patients ranged from 15 to 34, and all had a long history of heart trouble, dating in some cases from childhood. In 2 of the cases no lesion was found until more than 10 sections had been carefully scrutinized, showing the necessity of minute microscopic examination. In none of the cases was there any evidence of the coronary occlusion which has been reported by a number of writers, whose cases were tachycardia of ventricular origin. Nevertheless, the cause of the tachycardia was probably identical, namely, inflammation and degeneration. The authors' cases emphasize the role played by lesions of the myocardium in the etiology of paroxysmal tachycardia.

Posterior Pituitary Extract in the Prevention of Post-Operative Intestinal Distention.—In a preliminary report Philip C. Potter and R. Sterling Mueller describe a study undertaken at Bellevue Hospital for the purpose of working out a method for the prevention of post-operative distention and ileus. In a series of 100 abdominal cases they employed pituitary extract as recommended by Joseph A. Blake, in 1924, using one ampoule of surgical pituitrin after operation and continuing at intervals of four hours for six doses, or more if indicated. Although the incidence of post-operative distention was materially lessened, there were certain cases which continued to be a problem, namely, those in which considerable gas was present before the administration of pituitrin, and those in which distention appeared after the final dose of pituitrin had been given. It was evident that in certain cases pituitrin was started too late and in others its use had not been sufficiently prolonged. In a new series

of 100 operations, 50 for acute appendicitis and 50 for biliary disease, selected because distention seems more likely to occur in these conditions, the beta hormone of pituitary was employed. The routine adopted was as follows: In the cases operated upon under spinal anesthesia an initial dose of pitressin was given intramuscularly directly after operation, and continued every four hours for eight doses in the case of uncomplicated appendicitis, for twelve doses in the biliary cases, and for fifteen or more where acute appendicitis was complicated by peritonitis. In 90 of the 100 cases there was no distention, in 8 cases there was moderate distention. One extremely obese patient was unaffected by the drug, and in the remaining case there was mechanical obstruction necessitating an ileostomy. In twelve cases of biliary disease operated upon under general anesthesia, the action of pituitary extract was observed. In eleven of these cases a gradual generalized shrinkage of the small intestine was noted, but not of the degree seen in spinal anesthesia. This came on in from ten to twenty minutes after the administration of the pituitrin and remained throughout the operation, making for an extremely easy closure in all instances. In none of the twelve cases was any effect on the musculature of the stomach or large intestine noted.—*Annals of Surgery*, September, 1932, xvi, 3.

Cinchophen Poisoning.—Cinchophen, or 2-phenyl-quinoline-4-carboxylic acid, is also known as phenylcinchoninic acid, phenylcincholinic acid and as the proprietary preparations agotan, phenoquin, atophan and quinophan. It is also the chief component of neocinchophen, weldona, atquinol and diiodoatophan. T. G. Reah classifies the toxic manifestations of cinchophen poisoning as follows: (1) *Cutaneous*: Various rashes—scarlatiniform, purpuric, erythematous and urticarial. (2) *Vasomotor*: Palpitation, giddiness, collapse, fall of blood pressure, rapid pulse and cyanosis; these may follow even one dose of cinchophen. (3) *Gastro-intestinal*: Anorexia, nausea, vomiting, abdominal discomfort, or even severe epigastric pain may occur. (4) *Hepatic*: Jaundice is the first definite indication of involvement of the liver. At autopsy there is found destruction of liver cells; where the process is more chronic there may be widespread fibrosis and even attempts at regeneration of liver tissue. (5) *Renal*: Occasionally a transient albuminuria may appear. Reah found records of 35 cases of jaundice following the ingestion of cinchophen, including three unpublished cases from the records of the London Hospital. Of the 35 cases 18 terminated fatally. Factors which appear to have exerted an adverse influence are alcoholism, syphilis, pregnancy, and other conditions known to affect the liver. The toxic effects are not directly related to the amount of drug taken, the

milder symptoms having followed the ingestion of a single dose of $7\frac{1}{2}$ grains. In the more severe cases glucose should be given in large amounts, either by mouth or intravenously. It would seem reasonable to give insulin along with the glucose, but its administration should be controlled by estimations of the blood sugar. Calcium may be of value, as it appears to have been in one of the cases reported by Reah. Calcium salts should be given intravenously either in the form of calcium gluconate or of a 5 per cent solution of calcium chloride, which must be given very slowly. Cinchophen should not be used as a routine measure in the treatment of gout. Its use should be reserved for those cases in which other methods have proved inadequate. The patient should be tested for idiosyncrasy with a small initial dose, and if the drug is well tolerated 10 grains may be given three times daily for three days a week.—*The Lancet*, September 3, 1932, ccxxiii, 5688.

Therapeutic Use of Bacteriophage in Typhoid Fever.—During a typhoid epidemic in Donezbacken (Ukraine), I. E. Rutschko and M. I. Melnik had an opportunity to observe the effects of bacteriophage in 69 proved cases. General races of bacteriophage were employed, obtained from various sources. In 52 cases the treatment was given per os, and in 17 subcutaneously. In the former group, 10 c.c. of a bacteriophage preparation was given to the fasting patients, usually with a small amount of weakly alkaline soda solution. In the cases treated subcutaneously $\frac{1}{3}$ c.c. was injected once under the skin of the abdomen. In only a few cases was a second dose of the same strength required. The time of administration was generally at the beginning of the second week, but occasionally at the end of the second or beginning of the third week. In no case were any "negative" phenomena observed, but, on the other hand, no abortive effect upon the disease was seen. The reactions observed in most cases immediately after use of the bacteriophage were: (1) diarrhea, (2) fresh appearance of rose spots, and (3) increased sweating. These phenomena were more marked in those patients treated subcutaneously. Regardless of the day of the disease on which the bacteriophage was given, the temperature rose in nearly every case 0.3° - 0.8° C. during the next 48 to 72 hours, after which it fell 1° - 2° C., and then continued to decrease by lysis until normal. In a few cases it rose again 1° - 1.5° before undergoing lysis. Another no less important observation was that within 24 hours of administration the patients were free from delirium and a considerable improvement in their general condition was seen. In 50 per cent of cases the positive results were striking, in the other 50 per cent less marked. A few cases were hardly affected at all; these were mostly among those treated per os. There were 4 deaths (5.8 per cent), one

patient succumbing to an erysipelas infection and one to a pneumonic complication; a third was already in a hopeless condition when admitted. The mortality of control cases not treated with bacteriophage was 7.5-8.5 per cent. In the light of these results, it seems desirable to investigate further the effects of this form of treatment upon typhoid patients.—*Münchener medizinische Wochenschrift*, August 19, 1932.

A Case of Tuberculous Pericarditis with Effusion Treated by Means of Pneumopericardium.—In a search of the literature Giles W. Thomas found 16 cases of pericarditis with effusion treated by means of pneumopericardium, in all of which the author felt that the procedure gave symptomatic relief and slowed up the reaccumulation of fluid. He reports the case of a boy of 18 years, in which the diagnosis was acute serofibrinous pericarditis, probably tuberculous. Several pericardial taps were made during the first month of his hospital stay which yielded from 120 c.c. to 600 c.c. of fluid. A decided subjective improvement resulted although there was little clinical change. It was then decided to inject air the next time fluid was withdrawn. This was done and the patient stood the procedure well. As each 50 c.c. was withdrawn the blood pressure rose about 5 to 10 points, and when a similar amount of oxygen was injected, it fell about the same amount. As there was no apparent ill-effect from the procedure, it was repeated three times in the course of a week, and several times during the following weeks. The patient's condition improved to such an extent that he was discharged from the hospital. Six weeks later he was readmitted and examination seemed to indicate that he had an adherent pericardium. Cardiolysis was decided upon and performed. The pericardium, which was adherent to the heart was gently peeled off and large flaps were cut away. These pieces of pericardium showed lesions sufficiently typical to justify the diagnosis of tuberculosis in the healing stage. The tubercle bacillus had never been found in the fluid obtained by tapping. The patient survived the operation and was discharged to a sanatorium for general care. At last reports he had gradually increased his activities and was up and about for short periods daily. While pneumopericardium did not cure this patient, nor even prevent the necessity for operation later, this may have been because the treatment was not continued for a sufficiently long period. In order to prevent the formation of pericardial adhesions in pericarditis, it would seem, on theoretical grounds, preferable to keep the parietal and visceral pericardium apart by means of elastic gas rather than of inelastic fluid. The method of artificial pneumopericardium would seem to deserve more extensive trial than it has yet been accorded.—*American Heart Journal*, August, 1932.

Visceralgia: Reflex Dermatalgia.—According to J. Paviot and H. Jarricot, when a visceral organ is in a state of inflammation, 2 types of pain may be induced, in addition to spontaneous pain. The one type is that which may be elicited by the classic methods, such for example as pain on palpation at MacBurney's point. Pain of the other type, to which the authors are here especially calling attention, is induced by exploration of the dermal tissue by a procedure which they have termed the "pinch-roll" method, consisting of pinching up and rolling the superficial layers between the thumb and index finger. This produces in very limited zones a pain which the patient usually likens to that of a prick. These points of induced hyperesthesia, which do not coincide with the peripheral localization of spontaneous pain, occupy only a part of what may be called the zone of projection of the organ. Exploration of the skin by this technique shows that a visceral pain objectifies its peripheral repercussion in a given zone by vasomotor disturbances which impress upon the skin a special condition called by the authors cellular edema, or, better, "dermal cellulism" (cellulie dermique). The zone of cellulism forms a wide border around the hyperesthetic point revealed by the "pinch-roll." For any given visceralgia there is a corresponding "reflex dermatalgia." The existence of reflex dermatalgia is not confined to visceralgia; it is met with in a number of painful states, such as arthralgia, arthritis, neuritis, etc., but with this difference, that in these conditions it is not a constant phenomenon as it is in visceralgia. The zones recall "cellulism" conditions (a term preferable to cellulitis). Their pathogenic mechanism is reciprocally explained. Intradermal injection of double-distilled water at the dermal point of maximal intensity cause the cellular substratum of the reflex dermatalgia, or the placards of cellulism, to disappear, while at the same time the spontaneous pain and its train of sequels (functional impotence, etc.), if they exist, become modified. Analysis of these phenomena, in addition to its immediate diagnostic and therapeutic interest, makes it possible to envisage in a new light a number of problems of physiotherapy.—*Journal de médecine de Lyon*, August 20, 1932.

The Choice of an Anesthetic for Abdominal Surgery.—Finsterer, writing in the *British Medical Journal*, August 27, 1932, ii, 3738, summarizes the replies of 120 members of the German Surgical Society to a questionnaire asking for their views and experiences with various anesthetics. He also relates his own experience in 5,172 abdominal operations performed during twenty-five years under various methods of anesthesia. Chloroform caused most of the immedi-

ate deaths, especially at the beginning of narcosis. It injured parenchymatous organs, particularly the liver; it regularly induced intestinal atony, with frequent vomiting, often leading to death. Statistics from Austrian and German clinics showed that the immediate risks of ether were very slight. Of much greater importance were the so-called deaths from operative shock occurring from three to five days after the operation; they did not occur when deep narcosis was avoided. Prolonged ether narcosis injured or destroyed the normal powers of resistance, especially phagocytosis, so that the smallest infection, insignificant in operations under local anesthesia, led to death from peritonitis. Ether also favored pneumonia. Narcosis with nitrous oxide did not injure the parenchymatous organs, and was therefore least dangerous. Avertin was being used by 45 of the 120 surgeons who replied to the questionnaire. Finsterer, however, did not use this preparation as a basal anesthetic, owing to the frequency of unavoidable deaths (1 in 10,000 according to Specht), neither did he regard peritonect as harmless, for seventeen surgeons had reported five deaths from this anesthetic. Only 14 of the 120 surgeons used high spinal anesthesia, while 44 used spinal anesthesia for operations below the umbilicus.

In preparing patients for practically all abdominal operations Finsterer preferred regional, conductive, or paravertebral anesthesia with novocaine. In every laparotomy an exactly performed anesthesia of the abdominal walls was most important. This form of anesthesia was sufficient for gastrotomy, jejunostomy, colostomy, and also gastroenterostomy. In other operations at least mesenteric anesthesia procured with novocaine was essential. With splanchnic anesthesia operations on the gall-bladder, resection of the stomach and of the colon could be performed with a lower mortality than under general narcosis. Local anesthesia was absolutely without danger, prevented shock, and should be applied to spare general narcosis, even if this had been administered. In a series of 4,562 operations under local anesthesia Finsterer had only five deaths during operation or shortly after, in spite of the large number of bad risks. The mortality from pneumonia in 610 operations performed under general narcosis was 1.31 per cent; in 4,562 operations under local anesthesia it was only 0.24 per cent. In 843 patients, ranging in age from 60 to 88 years, the mortality was only 0.94 per cent. In aged patients with extreme arteriosclerosis it was advantageous to add pituitrin instead of adrenaline. Serious disease of the heart or lungs, extreme cachexia, and old age were no contraindications to an absolutely indicated operation.

LEGAL

PRIVILEGED COMMUNICATIONS— AN INTERESTING CASE

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Very recently an interesting case came before the Supreme Court which involved the construction and application of the statutory provisions of this State relating to confidential communications between patient and physician.

A woman had taken out a policy of insurance on her life in 1929 and she had died in the following year. The policy contained certain provisions to the effect that it should be void if the assured, within two years before the date of the policy, had been treated for a serious disease or if the assured had suffered from certain enumerated diseases. The beneficiary brought suit to recover the amount of the policy, and the insurance company set up as a defense that the assured had suffered from various diseases and had received medical treatment with respect thereto in violation of the policy provisions.

In order to establish its defense, the defendant at the trial called a certain Dr. J. who testified that he was a pathologist and that, while he had never treated the decedent during her lifetime, he had performed an autopsy upon her body after death. He testified that she had suffered from various ailments including cirrhosis of the liver, diseased kidneys, degeneration of the heart and general arterio-sclerosis. He further stated that the said diseases had had their beginning approximately ten years before the assured's death, and that for the three years prior to death had progressed to such an extent that the assured's health was seriously impaired, and further that the said conditions were caused by the excessive use of alcohol.

The testimony of Dr. J. was received over an objection on the part of the plaintiff, that it was improper and inadmissible as privileged under the section of the Civil Practice Act forbidding disclosure of professional information. It had been stipulated by the attorneys that the trial court should decide the issues in the case without a jury, and in ruling, in favor of the defendant the Court delivered an opinion in which the manner that that conclusion had been arrived at, was clearly and ably set out. In the opinion the court stated that the testimony vital to the case, namely, Dr. J.'s testimony, was admissible if at the time of the autopsy there was no existing relation of physician and patient between the deceased and the physician. The question thus presented, according to the Court, had never arisen in this State, but when it had come up in other juris-

dictions the courts had uniformly held that "a patient is a person under medical or surgical treatment and that a deceased body is not a patient, and that therefore, the relation of physician and patient ends when death ensues." The Court stated that on the basis of logical reasoning as well as on the said authorities outside New York State, there had been no relation of physician and patient in existence at the time of the performance of the autopsy, and therefore it permitted the testimony with respect to the autopsy findings to be considered, and directed judgment in favor of the defendant. The Court apparently felt as one case stated it, that "a dead man is not a 'patient' capable of sustaining the relation of confidence towards his physician which is the foundation of the rule given in the Statute, but is a mere piece of senseless clay, which has passed beyond the reach of human prescription, medical or otherwise."

One of the cases cited as authority by the Court in its opinion justifies its holding as follows:

"A deceased body is not a patient. The relation of physician and patient ends when the death of the patient ensues. To hold that facts discovered through an autopsy are privileged communications within the meaning of the Statute will not effectuate what we conceive to be its manifest purpose, namely, to obtain full disclosure to the physician in order to enable him to properly treat the patient. Treatment cannot avail after death. On the other hand, to hold that facts obtained by a physician through an autopsy are not privileged communications will not in our opinion, in any wise prevent the accomplishment of the purpose for which the Statute was enacted. The foregoing must be true, unless it can be said that a sick person will be deterred from calling a physician because of fear that, if death ensues, such physician will probably perform an autopsy and disclose the facts obtained through such autopsy. We think it altogether unlikely that such a fear would deter a sick person from securing the services of a physician. As a matter of fact, an autopsy is much less likely to follow in cases where the deceased person has had the services of a physician during his last illness. Where the deceased person has no physician during such illness the public authorities are more likely to require an autopsy and facts disclosed at an autopsy held at the instance of the public authorities are, of course, not

privileged. It follows that facts obtained at an autopsy are neither within the letter nor the spirit of the Statute; they are not within the letter because they are obtained after the relation has ceased; they are not within the spirit because keeping them secret will not in any wise accomplish the purpose for which the Statute was enacted. This Statute is in derogation of common law. In many cases it will close the door to the best possible evidence on the issue of fact presented for determination. It should not therefore be construed to apply to matters of evidence not coming clearly within its provisions."

Another of the authorities relied upon by the New York Court, in its opinion took occasion to discuss the wisdom of the enactment of a statute regarding privileged communications, and said in part the following:

"The enactment contemplates that a physician receives in confidence what his patient tells him, and also what the physician learns by a personal examination of the patient. It contemplates that the patient may testify with reference to what was communicated by him to the physician, and in that event only, it permits the physician to testify without the patient's consent. The express object is to exclude the physician's testimony at the patient's option, respecting knowledge gained at the bedside, in view of the very delicate and confidential nature of the relation between the parties. The statute recognizes that

they do not stand on equal terms. The patient is more or less suffering from pain or weakness, distracted by it, ignorant of the nature or extent of his injury or illness, driven by necessity to call in a professional adviser, sometimes with little freedom of choice, he relies, perforce, upon the physician's discretion as well as upon his skill and experience, and is obliged by the circumstances of his own condition not only to make an explanation of his ailment or injury, so far as it may be within his knowledge and may be communicable by word of mouth, but also to submit to the more intimate disclosures involved in a physical examination of his person. The physician on the other hand is in the full possession of his faculties and of that knowledge which is power. Manifestly, a patient occupies, for the time, a dependent position. The chief policy of the statute, as we regard it, is to encourage full and frank disclosures, by relieving the patient from the fear of embarrassing consequences."

In conclusion it should be noted that these cases are authority only for the proposition that the professional privilege does not apply to testimony as to autopsy findings. If the doctor who makes the autopsy treated the deceased in the deceased's lifetime, the doctor in testifying with respect to the autopsy, should not be permitted to disclose facts which came to his knowledge as a result of attending the deceased when the latter was alive.

TREATMENT OF LACERATION OF EYELID—LOSS OF EYE

A two and one-half year old child was brought to a hospital suffering from a laceration under the right eyebrow which he had received in falling on a milk bottle. The defendant was called upon to attend the child, and inserted three sutures in his treatment of the laceration. He found the right upper eyelid edematous and swollen, and an examination of the eye itself showed that it had apparently not been injured.

Two days after the child's admission to the hospital, it was determined that he had developed diphtheria, and the hospital authorities considered transferring the child to a hospital for infectious diseases. The doctor, however, succeeded in having the child sent to the home of his parents, where the physician continued his care of the case. He administered various doses of antitoxin to the child and continued his dressing of the wound.

After about a week the condition of the diphtheria was improving satisfactorily, but the wound near the eye developed an infection. The

doctor noticed some secretion in the eye cavity and called in an eye specialist, who found that a post-orbital infection had developed which would probably cause the loss of the eye. Under the direction of the specialist, the doctor each day thereafter probed the wound in the eye in order to release pus, and applied certain antiseptic medications. The patient made a good general recovery but developed a pan-ophthalmitis which rendered the eye useless.

Suit was brought against the doctor by the child's guardian, claiming that because of his carelessness the child's eyesight was destroyed and his face disfigured. The definite charge was, as developed at the time of the trial, that the defendant in treating the child's eye had punctured the eyeball and thereby caused blindness. The case was tried before a judge and jury, the trial lasting three days. The jury returned a verdict in favor of the defendant, thereby exonerating him from all charges of malpractice and terminating the case in his favor.

NEWS NOTES

SIXTH DISTRICT BRANCH

The Twenty-sixth Annual Meeting of the Sixth District Branch of the Medical Society of the State of New York was held on Tuesday, September 27, 1932, in the Masonic Temple, Binghamton, New York. This District is composed of the nine counties, Delaware, Broome, Tioga, Chemung, Schuyler, Tompkins, Cortland, Chenango, and Otsego, located in the south-central part of the State. (See map in Journal of Oct. 1, page 1137.) The county medical societies of the District have a membership of 428—the smallest in the State—and yet over one hundred, a quarter of the members, attended the meeting, and doubtless many more would have been present if the day had not been stormy.

Dr. Steuart B. Blakeley, of Binghamton, presided, and the Secretary, Dr. Hubert B. Marvin, also of Binghamton, recorded.

A noon luncheon was served by the ladies of the Eastern Star at one dollar a plate.

The program was a well-balanced combination of public health and society activities, and was of personal interest to every doctor.

The subject of the activities of a medical society as distinguished from the private practice of its members was presented by Mr. Homer Folks, Secretary, State Charities Aid Association, New York City, who spoke on the program recommended by the State Health Commission last fall. Mr. Folks said that the Commission had made 115 recommendations, of which he would emphasize only three.

Mr. Folks first discussed anti-tuberculosis work, and urged that special efforts be taken to prevent the usual increase in the number of cases during a time of economic depression such as this. He emphasized the need of special attention to epidemiological work in order to prevent the spread of the disease from the infected persons. The State is carrying out the recommendations of the State Health Commission that the State build three hospitals to treat tuberculosis cases coming from the smaller counties which could not support their own hospitals.

The second activity discussed by Mr. Folks was the control of venereal diseases. The number of cases of syphilis reported exceed that of tuberculosis. Length of time of treatment was a great factor in the cure and control of the disease, as in tuberculosis. No particular method of venereal disease control was advocated, for the speaker said that his organization was promoting results and not methods.

The adoption of the county as the unit of public health work was urged, in place of the present

independent units of towns and villages. Mr. Folks also discussed health insurance and said its principle was that a sick man was entitled to care by others,—the well members of his family, if possible, but otherwise by the community. The object is the promotion of the welfare of the community as distinguished from the individual; and mass service as distinguished from that to the individual. Mr. Folks did not fear that private practice would be seriously displaced by State medicine in the United States of America.

Dr. C. J. Longstreet, Health Officer of the city of Binghamton, referred to the friendly attitude of the doctors to the city venereal disease clinics, as shown by the fact that most of the cases had been referred to the clinic by the family doctors of the patients.

Dr. Martin B. Tinker, a member of the Advisory Committee of the Health Commission, referred to the need that promoters of county health units should use diplomacy in dealing with the health officers, who were faithfully protecting the health of the community.

Representatives of the State Medical Society, who were introduced at the luncheon, spoke on matters relating to medical society activities. Dr. F. H. Flaherty, President-elect, spoke of the influence of the excellent program in inspiring and educating the members.

Dr. D. S. Dougherty, Secretary, interpreted the attendance as convincing evidence of the growth and evolution of the civic and social aspects of the practice of medicine by family doctors.

Dr. O. S. Wightman, Editor-in-Chief, made a plea for a more extensive reporting of the activities of county societies in the Journal. He spoke of the permanent value of the record of the activities of the societies, and suggested that the reports include committee work as well as the formal meetings of the society as a whole. While the editors would prefer that the news items conform to the style adopted by the Journal, yet a more important consideration was their content, for the editors could mold the information to the approved form.

The scientific program consisted of two addresses, both most interesting in content and manner of presentation.

Dr. Hugh Auchincloss, from the Department of Surgery of the College of Physicians and Surgeons, New York, explained the principles of "Finger and Hand Destruction and Reconstruction," making effective use of charts and lantern slides to vivify his points and impress them upon the physicians.

Dr. Louis C. Kress of the State Institute for the Study of Malignant Diseases, Buffalo, took "Bone lesions" as his subject, and illustrated it in a unique way by the use of four projecting lanterns simultaneously, so that the audience had continuously in view the outline of the history of

the case, the appearance and pathology of the affected part, and the method of treatment.

The meeting of the Sixth District Branch was a pleasing demonstration of an effective way to arrange and conduct a meeting of a medical society.

THE SEVENTH DISTRICT BRANCH

The Twenty-sixth Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York was held on Thursday, September 29, 1932, in the Clifton Springs Sanatorium, Clifton Springs, Ontario County, New York.

The Seventh District Branch stretches across the west-central part of New York State from Lake Ontario to the southern boundary, and comprises the eight counties of Monroe, Wayne, Cayuga, Seneca, Ontario, Yates, Livingston, and Steuben. (See the map in the Journal, October 1, page 1137.)

The membership of the Seventh District is 781, of which 469 live in the county of Monroe in which the city of Rochester is located, and 322 in the other seven counties, which may be classed as rural. The attendance at the meeting was about 200, or one-quarter of the membership. The President, Dr. James M. Flynn, of Rochester, presided with grace and efficiency.

The program of the meeting was almost entirely scientific, and consisted of four papers.

"Cancer of the Uterus" was the subject of a paper by Dr. William P. Healy of Roosevelt and Memorial hospitals, New York City, who set forth the practical pathology of the condition simply and clearly by the use of lantern slides. He dwelt principally on the use of endothermia and diathermia. The paper was discussed by Dr. Louis C. Kress, State Institute for the Study of Malignant Diseases.

The next paper was given by Dr. George W. Crile, Director of the Surgical Service of the Crile Clinic, Cleveland, Ohio, on the subject "Indications for and the end results of denervation of the adrenal glands." Dr. Crile spoke of the relation of the adrenals to the thyroids. The adrenals are quick and explosive in their action, and in animals they are three times the size of the thyroids. Animals are alert and extremely responsive to danger signals, and yet they are likely to be sleeping between the times of danger. The thyroids are slower and more sustained in action, and in man are twice as large as the adrenals. The thyroid gives a slow, continuous stimulation, in distinction from the explosive action of the adrenals, and in man the thyroid and the brain are likely to overbalance the adrenals.

Dr. Crile discussed some newer knowledge of

the adrenals, and mentioned the good results which often follow the severing of the nerves of the adrenals in spastic conditions of the intestine. Dr. Crile's paper was discussed by Dr. William D. Johnson of Batavia.

The sanatorium served a noon luncheon, after which officers of the State Society were introduced.

Dr. F. H. Flaherty, President-Elect, spoke of the valuable work of the State Society in coordinating the activities of the county societies.

Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education, called attention to the graduate courses and to the civic duties of the physicians in promoting public health work.

Dr. D. S. Dougherty spoke of the advantages resulting from the social gatherings of the District Branches, and the cooperation growing out of the good fellowship.

Dr. O. S. Wightman, Editor-in-Chief, called attention to the Journal and its wealth of material, especially in regard to the activities of the county medical societies. He emphasized the importance of these records, and urged the secretaries and reporters to send accounts of their society activities to the Journal for permanent record and future reference. The officers and committeemen of the State Society look to the Journal as their principal source of information regarding the activities of county societies.

A piece of work well done by the smallest society is an example and inspiration to all the other societies, regardless of the size.

Two papers were presented during the afternoon session.

The subject of "Head Injuries" was presented by Dr. Foster Kennedy of the Neurological Hospital of New York City, and the paper was discussed by Dr. H. W. Williams, of Rochester.

Dr. Warfield L. Longcope, of Johns Hopkins Hospital, Baltimore, gave a paper on "The differentiation of chronic pyelonephritis from other forms of Bright's disease." The discussion was led by Dr. E. C. Riefenstein, of Syracuse.

The audience was unusually attentive and enthusiastic, and the meeting will be remembered as one of the best ever held in the District. The physicians were shown through the sanatorium by the Superintendent, Dr. Hubert Schoonmaker.

COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Medical Society of the State of New York met at the Hotel Statler in Buffalo on September 15th, 1932.

The following problems were considered at the morning session:

1. The adequacy of care of the orthopedic cases in Nassau County.
2. The preparation of a statement of the aims and objects of the Committee on Public Relations for this year.
3. A report of the Committee on the Professional Administration of the State-aided Lewis County Hospital.
4. A report regarding the medical problems of workmen's compensation administration in the State.
5. The appointment of a committee to study and report on the problem of the ratio of hospitals to population.

The afternoon session was a conference with the chairmen of the Public Relations Committees, or the Committees on Public Health, of the Medical Societies of Erie, Niagara, Wyoming, Orleans, and Chautauqua Counties.

The discussion brought out the fact that the Erie County Medical Society was about to take steps to become officially a member of the Health Council of Buffalo.

The discussion showed that the State Education Department's proposed activity for the early diagnosis of tuberculosis in school children should stimulate the interest of the family physician in the tuberculosis problem.

There was a free discussion regarding the activity of full-time physicians in State service engaging in the private practice of medicine. A committee was appointed to take up this matter.

The next meeting of the committee will be held in the month of October in Rochester.

JAMES E. SADLER, *Chairman*,
WILLIAM H. ROSS, *Secretary*.

AIMS AND OBJECTIVES OF THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Medical Society of the State of New York is undertaking this year to translate into county society activity the knowledge that it has gained of the problems of medicine in the last six years.

The aim of the Committee is to assist the physicians of the county medical societies in providing the best medical service possible. This is the prime objective. Achievement, however, will depend upon a number of factors, among which three stand out as important.

1. By creating harmony among all medical and public health workers. If the Committee on Public Relations can help to develop a common program between all agencies in health work, it will have accomplished one of its primary purposes.

2. By aiding the public to recognize good medical service. The rapid advancement in medical knowledge and medical practice makes it necessary to keep the public correctly informed, so that the people may reap the full benefit of the advancement in medicine.

The Public Relations Committees of the county societies should feel a responsibility to the people of their counties for a correct knowledge of what is good medical practice and what the conscientious citizen should do to protect his health. One of the serious conditions which must be thought of in publicity is the danger of encouraging self-diagnosis and self-treatment. The Public Relations Committee in entering this field should

stress particularly the importance of the advice and counsel of the family physician.

3. By stimulating physicians to become active members of public movements in health and welfare. Physicians should take a leading part in all health activities just as lawyers have done in political or historical activities. Physicians should have a similar feeling regarding their position in health and welfare activities, and they should feel that it is their prerogative to join with official bodies in developing health and welfare programs.

The technique of putting these suggestions into operation must be worked out by each county medical society committee. It is not expected that a program can be devised that will fit each county in detail.

A basic need is harmony and cooperation between the physicians represented by county medical societies, and the official and unofficial health organizations. Wherever public health can be directed by the local physicians, it should be done.

It is increasingly apparent to physicians that the problems of medical relations must be solved in the county society, and that the function of the State Public Relations Committee is to stimulate interest in the solution of medical problems by the county society, and to take leadership in the solution of problems that are State-wide.

There are many opportunities for the profes-

sion to improve public welfare and at the same time their own economic status, by helping to meet present day problems. To this end the Committee on Public Relations is holding, this year, regional conferences for the purpose of hearing a discussion of the problems of medicine from each county society of the State and for receiving their suggestions of how these problems

can be met; and then coordinating them into a policy of public relations which will meet the situation between the profession and the unofficial and official health agencies, and satisfactorily solve the economic relation of the profession to the administration of these services of whatever kind they may be.

THE PUBLIC RELATIONS COMMITTEE.

PRIZE ESSAYS

The Committee on Prize Essays desires to call the attention of the medical profession to the following prizes offered through the Medical Society of the State of New York.

The Merrit H. Cash Prize: This prize was established by Dr. Merrit H. Cash in 1863 and is given to the author of the best original essay on any subject in medicine or surgery. Competition is limited to the members of the Medical Society of the State of New York, who at the time of entering the competition are residents of New York State.

The essay shall be typewritten or printed, and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer. This essay must be an original communication and must not have been presented previously.

An idea of the type of subject upon which competitors may write their essays is indicated by the list of previous awards of this prize, which is as follows:

- 1864—A. N. Bell, Brooklyn: "How Complete Is the Protection of Vaccination, and What Are the Dangers of Communicating Other Diseases with the Vaccinia?"
- 1913—William Kirk, Jr., Troy: "Brown Sequard Paralysis: Review of Subject with Summation of Cases and Report of Case Resulting from Stab Wound of Autopsy."
- 1920—Herman B. Sheffield, New York City: "Present Status of Poliomyelitis."
- 1923—Arthur M. Wright and Edward M. Livingston, New York City: "Leucocytosis of Internal Hemorrhage."

The Lucien Howe Prize: In 1906, the late Dr. Lucien Howe, then residing in Buffalo, presented the State Medical Society with a prize fund, the interest of which is to be used by the Society for the presentation of a suitable medal for the best original contribution to our knowledge of some branch of surgery, preferably ophthalmology.

The author need not be a member of the Medical Society of the State of New York.

"The method of presenting the communication and of awarding the prize shall be substantially the same as that followed in regard to prize essays. That is to say, the communication shall be typewritten or printed, and the only means of identification of the author shall be a motto or other device. It shall be accompanied by a sealed envelope having on the outside the same motto or device, and containing the name and address of the writer. If, in any year, the committee does not deem any essay or communication which is offered worthy of the prize, then it shall not be awarded, and the interest for that year shall be added to the principal."

In the past this prize has been awarded as follows:

- 1914—Mark J. Schoenberg, New York: "Contribution to the Experimental Study of Ocular Anaphylaxis."
- 1918—Israel S. Wechsler, New York City: "Ophthalmic Changes in Tabes and Paresis—Pathology and Diagnosis with Reference to Cerebrospinal Syphilis."
- 1922—Arthur J. Bedell, Albany: "Some Observations with the Gullstrand Slit Lamp on the Lens, Including Cataract."
- 1924—Arthur J. Bedell, Albany: "Study of the Vitreous."
- 1927—Arthur J. Bedell, Albany: "Photographs of the Fundus Oculi; Normal and Pathological Conditions."

Prize essays must be submitted before January 31, 1933. They must be directed to the Committee on Prize Essays, Medical Society of the State of New York, 2 East 103rd Street, New York City.

If any identification marks other than the ones prescribed are attached to the essay, it will be disbarred from the competitions.

HENRY H. M. LYLE, *Chairman*,
MARTIN COHEN,
JOSHUA E. SWEET,
Committee on Prize Essays.

DUTCHESS-PUTNAM COUNTY

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, September 14, 1932, at the Wassaic State School for mental defectives, Wassaic, N. Y.

An inspection was made of the institution after which Dr. Arthur W. Pense, acting in the absence of Doctor Storrs, gave a clinic at which interesting cases were presented. Following this there was a business meeting at which the following candidates were elected to membership in the County Society:

Dr. Thomas S. White, Millbrook, N. Y.; Dr. Alice Stone Woolley, Poughkeepsie, N. Y.; Dr. James J. McGrath, Poughkeepsie, N. Y.; Dr. William H. Meyer, Poughkeepsie, N. Y.; Dr. Walter C. Nelson, Fishkill, N. Y.; Dr. Alexander Heller, Matteawan State Hospital, Beacon, N. Y.; Dr. Arthur W. Pense, Wassaic State School, Wassaic, N. Y., by transfer from Binghamton State Hospital, Broome County.

Doctor J. E. Sadlier reported the work of the Cancer Committee, and moved that sufficient money, not to exceed \$100.00 at the present time, be voted from the treasury to meet the expenses of the committee. This was seconded and carried.

Doctor Aaron Sobel introduced the following resolution:

BE IT RESOLVED, that the Dutchess-Putnam County Medical Society request the Board of Health of the City of Poughkeepsie not to open its venereal disease clinic for the treatment of rural cases.

BE IT FURTHER RESOLVED, that if the State Department of Health has any suggestions on health matters, that they be presented by the District Health Officer to the Dutchess-Putnam County Medical Society for first consideration.

BE IT FURTHER RESOLVED, that a copy of these resolutions be sent to the Chairman of the Committee on Venereal Disease of the Board of Health of the City of Poughkeepsie, and to Dr. Thomas Parran, Jr., State Commissioner of Health, Albany, N. Y.

Meeting adjourned at 6:00 P. M. for dinner.

Present: Drs. Deyo, Richie, Krieger, Breed, Marks, Sadlier, Carpenter, Hoag, Tabor, Appel, Niles, Roberts, Borst, Cavanaugh, Thompson, White, Harrington, Folsom, Sobel, Jennings, Pense, Vanderburgh, Rodgers, Peckham, J. N. Boyce, Hitchcock, Gordon Mackenzie, Gilbert Mackenzie, George—6 nurses—35.

H. P. CARPENTER, M.D., *Secretary*

ROCKLAND COUNTY

The fall meeting of the Medical Society of the County of Rockland was held on Wednesday, September 28, 1932, in Letchworth Village, the State institution for the care of medical defectives, in Thiells.

The scientific session was addressed by Burton T. Simpson, M.D., Director State Institute for the Study of Malignant Disease, Buffalo, N. Y., on the subject of "The responsibility of the medical man in the control of cancer." Dr. Simpson outlined the principles of cancer control in a simple, convincing way, and told of the means which the family doctor has at his control or service for the detection and treatment of the disease.

Luncheon was served at 5 p.m., the members being the guests of Dr. Charles S. Little, Superintendent of the Institution.

The Secretary announced a series of post-graduate lectures on the subject of traumatic surgery, to be given under the auspices of the committee on Public Health and Medical Education of the State Society. These lectures will be given in the Recreation Hall of the Summit Park

Sanatorium, Pomona, on Friday afternoons at 3:45 p.m. The subjects are as follows:

October 7th—John J. Moorhead, M.D., F.A.C.S., Fractures in general. The treatment of common fractures.

October 21st—Herbert M. Bergamini, M.D., F.A.C.S., Care of head injuries.

October 28th—David M. Goldblatt, M.D., The treatment of fractures of the femur and humerus.

November 4th—Emmett A. Dooley, M. D., The treatment of fractures of the forearm and leg.

November 11th—Henry H. Ritter, M.D., F.A.C.S., The treatment of burns and hand infections.

November 18th—Harry V. Spaulding, M.D., F.A.C.S., Abdominal injuries.

November 25th—Willias W. Lasher, M.D., F.A.C.S., The treatment of joint injuries.

W. J. RYAN, M.D., *Secretary*

Mr. and Mrs.—

Anybody's Word But Your Wife's

From New York Herald Tribune, August 5, 1932.

BARBER RACKET

The New York *Sun* of September 12 has the following account of a new racket worked by barbers in New York City:

"The up-to-date barber in a 'gyp' shop poses as a specialist in treatments of the scalp and shows what purports to be a diploma issued by Prof. So and So. Having thus prepared the victim for treatment of his head and bank roll, the barber discovers that he is suffering from an attack of 'skees pus,' puts him through an elaborate course of sprouts, charges him all he appears to be able to stand and, if he is still receptive, sells him a bottle of scalp revivifier for a couple of dollars, which is nothing but colored alcohol and water.

"The Better Business Bureau, 280 Broadway, has received numerous complaints against the 'gyp' barber shops, but owing to the reluctance of the victims to appear against the swindlers in

court has been unable to make much headway against them. The Board of Health has had more success and only a short time ago revoked the license of a Grand Central area barber. A short time ago a policeman of the West Thirtieth Street precinct underwent the 'gypping' process in a barber shop near the Pennsylvania Station, arrested the barber and had him fined \$25 in a police court.

"The Better Business Bureau told of a boy jockey from Miami who didn't have much more beard than a debutante. He went through a course in a barber shop near the Penn. station, got a bill for \$4.70 and paid it. But, being a jockey, he complained to the first policeman he met and the policeman went back with him to the barber shop and got his money back.

"I'll give it to the little stiff because I don't want any trouble," the proprietor explained."

MEDICINE SHOWS

The New York *Herald Tribune* of September 28 has the following editorial comment on medicine shows:

"For all that the sophisticated city dweller knows, the oldtime medicine show, once as familiar as chin-whiskered Silases, corn huskings and other forms and emblems of country carnival, might have passed into utter oblivion, to be remembered only in the folklore of pastoral reaches and flag-station towns. Such, however, is not the case. Turn any week to the delightful insertions in the magazine "Billboard," where, a little beyond the shopworn lion advertisements, you will come across an

enchancing encyclopedia of medicine show dispatches and information, and only last week a dispatch to 'The Morning Telegraph' recorded the blithe progress of a medicine show company through the transalpine uplands of Pennsylvania. 'We are selling the Oregon Indian remedy, "Katonka,"' writes the correspondent. 'I sold it thirty-five years ago and it goes over right today. We sold a dozen or so last night at a buck a throw and a lot of Indian Oil and Corn Salve.'

This recalls a description of such a show that appeared as an editorial in this Journal of August, 1925.

OUR NEIGHBORS

CERTIFICATION OF SPECIALISTS IN NEW JERSEY

The Medical Society of New Jersey has given serious consideration to a plan for the certification of specialists by the State Society. An outline of this plan was printed in this Journal of July 15, 1931, page 928.

The plan was further developed on May 29, 1932, by the Welfare Committee which voted to submit the plan to the House of Delegates which met on June 15, 1932. This plan was printed in the Journal of the Medical Society of New Jersey of July, 1932, page 591, and is as follows:

"A special committee of the State Society shall be appointed to be known as the Committee on Credentials of Specialists, to be composed of the President and Secretary, and the Chairman of the Welfare Committee, Chairman of the Board of Trustees, the Secretary of the State Board of Medical Examiners, and First Vice-President.

"Each component county medical society shall set up a similar Committee on Specialist's Credentials for a period of three to five years, composed of its President and Secretary and three other members to be elected by the county society."

The applicant shall fill out a blank form of application to be supplied by the State Society and submit it to the County Society Committee. If this committee approves the application and credentials, it shall send it to the State Committee for final judgment. The certification shall be awarded at the annual meeting of the State Society. A charge of \$25 shall be made to defray the costs of the procedure.

The following conditions may be considered favorable recommendations in judging an applicant's qualifications for certification:

1. General reputation as an honest, conscientious, and ethical physician.
2. Membership in national societies, such as the College of Surgeons, or a diploma from a national examining board such as that in ophthalmology.

3. An experience of at least five years in the practice of the specialty in a hospital.
4. Post-graduate courses in recognized medical schools.
5. Evidence of continuous, active, successive practice during at least ten years, marked by study, travel, active membership in medical societies, and proof of special ability in their chosen fields of practice, will be deemed worthy of consideration.

The supplement of the September Journal of the Medical Society of New Jersey records the following discussion of the plan when it was presented to the House of Delegates on June 15, when Dr. Schauffler said:

"The Welfare Committee of the State Society has had that matter up for three years now, combating attempted legislation introduced by laymen, and possibly some physicians whose names are unknown, trying to force through the Legislature a law making specialists subject to another examining board, and insisting that this certification shall come from the State.

"The Welfare Committee has threshed this over for several years and, in order to avoid another step into State medicine, in order to avoid political interference with the duties and privileges of the medical profession, this matter has been most carefully considered, and it has seemed to the Welfare Committee members that if some method could be devised by which the whole thing could be kept in the hands of the medical profession instead of getting into the Legislature and into the hands of politicians, it would save the respect for the medical profession, it would really amount to something in the way of certification, and it would be pleasing to the public at large; therefore, the Welfare Committee has thoroughly approved of a procedure of this kind and, after long deliberation and many conferences, this plan has been evolved."

The motion to adopt the plan as reported by the Welfare Committee was carried.

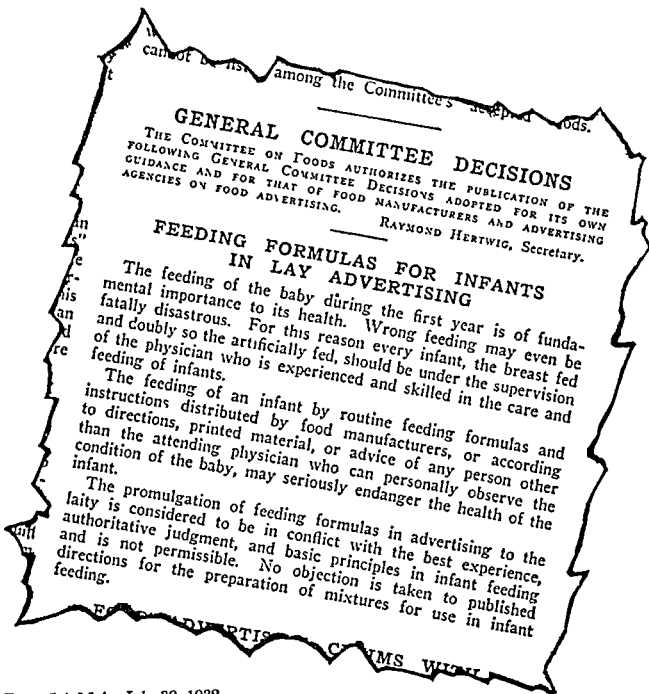

MEDICAL DIRECTORY FOR NEW JERSEY

The House of Delegates of the Medical Society of New Jersey considered the relation of the Medical Society of New Jersey to that of New York in regard to the Medical Directory of New York. The minutes of the meeting of June 15, published as a supplement to the September Journal, say:

"*Dr. Wells P. Eagleton:* The Directory of the New York State Medical Society contains a list of physicians in New Jersey and in Connecticut, in addition to its own roster. That is furnished to the members of the New York Medical Society for nothing. It seems to me that instead of

Maltcao
BUILDS FOR THE YEARS AHEAD

(Continued from page 1210)

our starting another directory, it would be a simpler matter to work in cooperation with the New York State Society, to furnish them the data, and for us to receive a certain number of copies of the directory. Personally, I buy it every year because it is the best directory around this region. It would not cost the New York Society very much more to issue a sufficient number of copies to supply the New Jersey members. I offer that as a suggestion.

"*Dr. Jaffin:* For a number of years I have written to the New York State Society concerning this exchange and have met with no results whatever. They have, apparently, adopted a policy of abandoning the former liberal listing of physicians in New Jersey and Connecticut. Recently, in the *New York Medical Week*, similar criticism has been raised, by members of the New York County Society, about this very omission, and if the New York Medical Society will list them as fully as they do members of their own Society, it would be quite satisfactory and would spare us making this venture, but they have refused to do it for so many years, that I thought it would be a good thing to bring the question before this State Medical Society.

"*Secretary Morrison:* If my recollection is correct, about seven or eight years ago the New York State Medical Society approached us about sharing the cost of such a directory and this State Society took no action. It appears to me far cheaper to again open negotiations with the New York State Medical Society, asking for information as to what our share of the cost would be to have our State listed as fully as their own. It probably would be only about one-quarter what the issuing of a directory of our own would cost."

The House adopted the following resolution:
"Resolved, That the Medical Society of New Jersey shall communicate with the Medical Society of New York and find out what would be the proportionate cost of including our membership in their directory."

HOUSE OF DELEGATES IN NEW JERSEY

A seventy-five-page supplement to the September issue of the *Journal of the Medical Society of New Jersey* devotes fifty pages to the minutes of the House of Delegates on June 15, 1932, including the annual reports of the officers and committeemen, all of which were recorded as having been read at the meeting.

The House discussed a wide range of subjects, including a plan for the certification of specialists, which was outlined in the *New York State Journal* of July 15, 1931, page 928.

The subject of continuing the employment of a field secretary to do educational work among school children elicited opposition which was

nd a directory

NOMINATING COMMITTEE IN NEW JERSEY

The supplement to the September issue of the
Journal of the Medical Society of New Jersey
contains five pages of discussion on an amend-
ment to the constitution in regard to the com-
mittee appointed to make nominations for offi-
cers of the Society to be elected at the annual
meeting in June The following resolutions were
passed

'This committee shall meet on a date in March
ufficiently early for its report to be published
in the April number of the Journal, and it shall
report in that number of the Journal the result
of its deliberations in the form of a ticket con-
taining nominations for each office to be filled

'Candidates other than those offered by the
Nominating Committee, may be nominated for
any or each office, provided that such nomina-
tions are proposed by at least fifteen members
of this Society, who number at least five from
each of at least three different component soci-
eties, and provided further that such other nomi-
nations are made in time to be published in the
May issue of the Journal'

RESOLVED, That this Society permit of the
advertising, in the March issue of the Journal
the names of members who have been endorsed
by their own respective Component Society as
candidates for office in this Society, and, that in
the same issue of the Journal there shall be ad-
vertised the complete membership of the Nomi-
nating Committee by name and county"

JOURNAL IN NEW JERSEY

The annual report of the Publication Commit-
tee of the Medical Society of New Jersey is con-
tained in the supplement to the September Jour-
nal, and says

'The Publication Committee again reports a
very successful year Our total expense for the
year was \$14,492.92, our net receipts were
\$8,857.60, leaving a deficit of \$5,635.32, which
was paid by the State Society As we have a
membership of about 2,830, this makes the cost
of the Journal \$1.99 per member, a material re-
duction from any previous year

During the year we published 122 original
articles, most of which were written by our own
members, using 770 pages to do so In addition,

Solving the problem of MALNUTRITION in children who won't drink milk

Many children dislike milk, refuse to drink it — with
the result that they are underweight and poorly
developed

For such children—for all growing children—Cocomalt
in milk is recommended Not only do children love its
delicious, chocolate flavor, but, mixed with milk accord-
ing to directions, it adds 70% more nourishment (food-
energy). It provides extra proteins, carbohydrates and
minerals (calcium and phosphorus)

Cocomalt contains not less than 30 Steenbock (300
ADU) units of Vitamin D per ounce This rich supply
of Vitamin D makes possible a more efficient utilization of
the calcium and phosphorus furnished by Cocomalt and
milk for the formation of strong bones, sound teeth and
sturdy bodies High in food value, low in cost At grocers
and drug stores in ½ lb., 1 lb., and 5 lb. size

Accepted by the American
Medical Association
[COMMITTEE ON FOODS]

Cocomalt is accepted by the American Medical Asso-
ciation Committee on Foods and is licensed by the
Wisconsin Alumni Research Foundation under Steen-
bock Patent No. 1,680,818

Free to Physicians

We will be glad to send a trial can of Cocomalt free to
any physician who sends his name and address to R. B.
Davis Co., Dept. 71 S., Hoboken, N. J.

Cocomalt

Cocomalt is a scientific food concentrate of selected
cocoa, barley malt extract, partially defatted milk
sugar, eggs, flavoring and added Vitamin D
ADDS 70% MORE NOURISHMENT (FOOD-ENERGY) TO MILK
(Prepared according to label directions)

FOR CONSTIPATION

...
**safer and
more effective**

As a contrast to the irritant and unnatural action of the usual cathartics, more and more physicians are recommending the use of a natural bowel corrective in

PSYLLA (Plantago Psyllium)

Do not confuse Psylla with the ordinary commercial psyllium, because Psylla has been subjected to a number of cleansing processes to rid the original seed of waste material and to render it **SAFE FOR HUMAN USE**.

Psylla, therefore, is not only more wholesome but more therapeutically effective. It provides the maximum of bland bulk and lubrication in the bowel.

NOTE: Psylla is carefully cleaned and **sterilized**. There is an inner seal in each can as a guarantee of its wholesomeness.

S·M·A·CORPORATION

of Cleveland, Ohio, announces to the medical profession that it has been awarded sole rights for the ethical distribution of

VITAMIN D

produced from Cod Liver Oil
under license United States patent 1,678,454
issued July 24, 1928, developed in the laboratories of and controlled by Columbia University.

This is Natural Vitamin D, not an irradiated product, and not a cod liver oil concentrate, but rather a highly potent extract of the antirachitic principle of cod liver oil. It is extracted and prepared in suitable form for therapeutic use by methods developed by Doctor Theodore F. Zucker, Assistant Professor of Pathology at the College of Physicians and Surgeons of Columbia University.

This Vitamin D is now available for therapeutic use in 5cc and 50cc bottles. *The concentration is such that 10 drops is equal in Vitamin D potency to three teaspoons of standard potent Cod Liver Oil.* It is palatable and free from objectionable taste. This new product will be ethically advertised and carefully distributed through prescription pharmacies. It will be sold at prices approximately the same as those current for equivalent dosages of plain Cod Liver Oil. Interested physicians are invited to write for full information and complimentary samples to S. M. A. Corporation, 4614 Prospect Ave., Cleveland, O.

THE PLACE OF *Puretest* MINERAL OIL

in Bowel Management

Mineral Oil is not open to the objections made to other forms of laxatives. This is because its action is largely mechanical.

Puretest is a very highly refined mineral oil of uniformly high viscosity and specific gravity (up to .895 at 25° C.). This insures a maximum of penetration and lubricating action which is of particular regulative value in the following conditions:

THE NORMAL BOWEL IN OCCASIONAL LAPSES

Puretest Mineral Oil softens the food wastes and enables them to slide easily through the intestinal tract, even in a weakened peristaltic condition.

THE BOWEL CRIPPLED BY EXCESSIVE USE OF LAXATIVES

Colons injured by chronic constipation have usually lost some of their normal lubricating mucus. Puretest Mineral Oil is an excellent substitute.

THE BOWEL HANDICAPPED BY CERTAIN AILMENTS

In cases where a bland diet is required, such as chronic gastritis, gastric ulcer, or where there is a tendency to spasm in the colon as in spastic colitis, or in any painful form of constipation, Puretest Mineral Oil is a soothing and effective agent.

THE CONDITION KNOWN AS "AUTO-INTOXICATION"

Tests show that Puretest Mineral Oil is highly absorbent of decomposition proteid products in the intestinal tract such as indol, skatol and histamine. These poisons, according to many authorities, are the cause of the condition known as "auto-intoxication" and its train of depressing symptoms.

This report says nothing about the three items of expense for rent, for clerical hire, or for the editorial proportion of the salary of the executive secretary and editor which would amount to about three thousand dollars.

MEDICAL INSURANCE IN NEW JERSEY

The Medical Society of New Jersey promotes three forms of insurance for its members:

1. Medical defense and indemnity.
2. Health and accident.
3. Automobile.

The annual reports on these lines of insurance are contained in the Supplement of the Journal for September.

Indemnity Insurance: The report on indemnity insurance reads:

"In 1921 the Medical Society of New Jersey entered into a contract with the U. S. Fidelity & Guaranty Co., of Baltimore, to defend and indemnify its members against malpractice claims. Since then there has been a steady growth each year in the number of members taking advantage of this form of protection.

"The number of doctors insured up to date is 1,886, which represents 67% of the total membership of 2,821.

"On February 4, 1932, a special meeting was held in Newark, at which were present the President, Secretary, Councilors and other officials of the Society, and representatives of the Company. On behalf of the Company, it was pointed out that during the past two years the number of claims in proportion to the total membership of medical and dental societies had increased, and the loss ratio had been correspondingly greater. The desire was expressed to maintain the existing premium rates. It was not the intention of the Company to advance its present schedules, unless the loss situation became more acute.

"As a result of the discussion, it was arranged that the Company would forward a report of each claim, as received, to the committee and to the Judicial Councilor of the district in which the claim happened to be made, so as to keep them informed. It was also decided to urge every insured member to cooperate with the Company, to limit and minimize the number of suits, by exercising the utmost vigilance in treatment and management of all patients.

"During the past year there were 29 claims settled at a total cost to the Company of \$19,127.58; 47 cases were pending, against which the Company has set up reserves of \$14,500; there were 74 claims in all."

Health and Accident Insurance: The report on health and accident insurance is as follows:

"This report is for the year ending April 15, 1932, and covers the two kinds of insurance pol-

(Continued on page 1217—adv. xvii)

(Continued from page 1216—adv. xvi)

icy offered to our members, that on Health and Accident, of the Independence Indemnity Company, consolidated with the Commonwealth Casualty Company, in which name the policy was formerly issued and which still remains the Commonwealth Division of the merged companies.

"The improvements made last year in the contract, have given increased advantages and greater satisfaction: (1) Extension of the period of indemnity for sickness to 6 weeks, instead of 4; (2) provision for covering total disability for work, even though the policy-holder be not strictly 'house-confined.'

"Further progress has been made this year in the Company's establishing a new State Agency to cover the whole State, thereby increasing means of contact with the company by our members.

"Number of members now insured:	
"Ages—under 50	91
50 to 60	63
over 60	49

Total203"

Automobile Insurance: The report on automobile insurance reads:

"Our Automobile Policies are standard policies issued at standard rates, but offered to our members at discounts which amount to 15 or 20%, plus annual dividend of about 15%. The law requires that separate companies carry the risks on casualty and fire and theft, but our companies are so associated that the policies are issued under one 'cover,' thus facilitating our dealing with only one agency.

"Number of members carrying liability and property damage.....	276
"Number carrying fire and theft policies	76
"The experience of the year shows premiums written	\$12,976.22
"Premiums earned (for time to date)	\$6,488.11
"Losses incurred	\$3,134.08
"Loss ratio	48.30%

"The committee's work has incurred no expense whatever to the Society, the office work being free, and even the stationery used being from the previous year."

JOURNAL OF MINNESOTA

The annual report of the Editing and Publishing Committee of the Minnesota State Medical Association, appearing in the September number of *Minnesota Medicine*, is devoted principally to the costs of the Journal, as follows:

"Effective January 1 the Editing and Publishing Committee decided to standardize on a 100-

SARATOGA HATHORN

A Naturally Carbonated Mildly Purgative MINERAL WATER

STATE OWNED AND STATE BOTTLED

This effective sparkling laxative water contains the following solids:

Ammonium chloride	\$3.54	Sodium Nitrite	Trace
Lithium chloride	65.25	Sodium bicarbonate	241.23
Potassium chloride	72.97	Calcium bicarbonate	3,962.24
Sodium chloride	11,290.17	Barium bicarbonate	46.83
Potassium Bromid	120.00	Strontium bicarbonate	Trace
Potassium Iodid	1.60	Ferrous bicarbonate	9.38
Sodium sulphate	Trace	Magnesium bicarbonate	2,837.48
Sodium metaborate	Trace	Alumina	15.50
Sodium Nitrate	Trace	Silica	9.20
TOTAL SOLIDS	19,376.70		

Note Results in milligrams per liter.

SARATOGA HATHORN is a mild but extremely effective purgative because of the presence of magnesium bicarbonate, sodium chloride, the alkaline bicarbonates and carbon dioxide gas. Hathorn has proved beneficial in hyperacidity occurring in cases of acid catarrh of the stomach and atony of the stomach. Especially favorable results have been obtained in cases of dyspepsia due to mental overexertion. It is not recommended for patients with nephritis.

Upon written request, we will gladly send a complete analysis and a complimentary carton of Saratoga mineral waters, including 2 bottles of Geyser and 1 bottle each of Hathorn and Cessa.

page journal monthly. Other economies have also been effected. If this standard of 100 pages is adhered to throughout the year, which it undoubtedly will be, it is almost certain that the publication of the journal for 1932 will show a surplus. For the first quarter of the present year our report shows a net surplus of \$494.70. The May number contains the largest volume of local advertising that any issue of the journal has ever carried, and plans are under way by which it is hoped to materially increase local volume of display advertising for the year. Obviously this depends to some extent upon general business conditions but, regardless of the very unfavorable conditions in all lines of business, we feel safe in promising that there will be no deficit for the present year.

"All kinds of publications have experienced tremendous losses in advertising volume during the past two years, and no relief of any consequence is anticipated for 1932. This volume loss is chargeable mainly to national business, all of which is handled through the Cooperative Medical Advertising Bureau, an auxiliary of the American Medical Association. *Minnesota Medicine* volume for 1932, in this class of advertising, compares more than favorably with other state journals. This is due in no small de-

gree to the high standing and fine reputation which the journal has throughout the country. But, as before stated, the Editing and Publishing Committee has reduced the size of the journal for 1932 and effected other economies which should be sufficient to more than provide for the anticipated loss of volume and leave a surplus for the year.

"At the close of the year our records show that subscriptions of two dollars were paid on 2,063 members, and that the journal was still being mailed to 135 delinquent members. There were upon our list 103 doctors paying the annual subscription of \$3.00, who are not members of the State Association. There are being mailed out monthly 359 copies on the complimentary list, to exchanges, to advertisers, etc., leaving a surplus each month of approximately 140 copies. A large number of these surplus copies is used in supplying miscarried copies, as samples to advertising prospects, and to prospective non-member subscribers."

A table shows that the advertising income was \$9,966.84, and members' dues of two dollars allocated to subscriptions to the Journal yielded \$4,126, a total net income was \$13,188.94. The expenses were \$14,915.20, leaving a deficit of \$1,726.26. No items were charged for salaries or rents.

EX-PRESIDENTS IN MINNESOTA

The annual report of the Secretary of the Minnesota State Medical Association contains the recommendation that four ex-presidents be added to the Council of the State Society. The minutes of the House of Delegates, printed in the September number of *Minnesota Medicine*, contains the following comment by Dr. A. G. Schulze of St. Paul:

"It is suggested that there be added to the Council four additional members consisting of the four past presidents whose terms have last expired. We believe that in this way we shall retain this all-valuable service of the men who know most about our program, history and precedents established."

"The purpose of this is to not lose abruptly the services of the men who have served, at the expiration of their short terms. The idea is to retain these men for a period of four years longer, to give of their wisdom and of their judgment to the Council. I think that is very good. The Councilors now consist of the nine Councilors, together with the President, the President-elect and the Secretary and Treasurer as ex-officio members. We add four more to that, which makes thirteen, and with the officers, the President, President-elect, Secretary and Treasurer, it is seventeen."

This suggestion was put to vote and carried.

PROFESSIONAL HOUSE

In all their dealings, The Drug Products Co., Inc., of 26-35A Skillman Avenue, Long Island City, New York, can truly be called a "Professional House." In every department in this well-equipped establishment, the research and testing laboratory, the digitalis standardization department and the Pulvoids department every consideration is given the physician and the prescription pharmacist.

And, of course, in this matter of Pulvoids—this is one way in which The Drug Products Co., Inc., has pioneered. Believing that hard, compressed tablets are not nearly so effective as ingredients loosely aggregated, this company first originated Pulvoids in 1913. The manufacturing process necessary to make Pulvoids and insure prompt and complete disintegration by the gastric juices is unique from a physiological point of view and is due to the basis of Pulvoids structure, which is carbo-

hydrate. Saliva, through its diastasic action of ferment and water, ingests the carbohydrate in the stomach and brings the Pulvoid ingredients into contact with the columnar epithelial cells of the stomach. This affords rapid and unadulterated absorption of the medicaments in the pulvoid.

Have you seen a copy of Drug Products News, the attractive house organ of The Drug Products Co., Inc.? This contains interesting news of happenings at The Drug Products laboratory and also gives brief comments on up-to-date happenings in matters purely medical. This is another way in which The Drug Products Co., Inc., fulfills its obligation to the medical profession as a "Professional House." See page xxiii.—*Adv.*

ANNOUNCES NATURAL VITAMIN D EXTRACT

Vitamin D, in the form of extract of cod liver oil, is now available to the medical profession, according to announcement by S.M.A. Corporation of Cleveland, Ohio, which has just announced the availability of primary vitamin A.

This vitamin D is not an irradiated product and not a cod liver oil concentrate. Instead it is a highly potent extract of the antirachitic principle of cod liver oil.

It is extracted and prepared in suitable form for therapeutic use by methods developed by Dr. Theodore F. Zucker, Assistant Professor of Pathology at the College of Physicians and Surgeons of Columbia University. It is produced under license United States patent 1,678,454 issued July 24, 1928, developed in the laboratories of and controlled by Columbia University.

This vitamin D concentrate is palatable and free from objectionable taste. The concentration is such that ten drops are equal in vitamin D potency to three teaspoons of standard potent cod liver oil.

The company announced that it will be available for therapeutic use

in 5 c.c. and 50 c.c. bottles, and it will be ethically advertised and distributed through prescription pharmacies at prices approximately the same as those current for equivalent dosages of plain cod liver oil. Sole rights for the ethical distribution of this vitamin D concentrate have been awarded to S.M.A. Corporation.

A combination of primary vitamin A and vitamin D concentrate is soon to be offered to the medical profession by S.M.A. Corporation. The concentrated combination will permit the prescribing of both vitamins A and D in minimum doses. None of these new products carry any directions for dosage on the package and all of them carry the words "Use as directed by your physician." See page xv.—*Adv.*

S. EITINGER ACQUIRES NEW QUARTERS

The firm of S. Eitinger, manufacturers and fitters of surgical appliances, leases new offices at 714 Avenue, New York City. The move from its old address, at 55 Avenue inaugurates a new era of enlarged activity from the new quarters which it has taken over.

S. Eitinger is a long established organization in its particular field. Throughout its business career it has scored a worthy record which makes it loom at the present time as one of the outstanding manufacturers in surgical appliances. This repute it has built up through rendering careful service, and distributing only high-standard products, factors that have been fundamental in the firm acquiring a widespread good will and prestige.

The fine record it has made will be maintained at the new headquarters it has taken at 714 Lexington Avenue. Here have been secured spacious quarters with ample facilities to continue a noteworthy record. All of the most modern facilities will be incorporated and nothing will be neglected to insure the convenience of all clients who will do business there. See page xviii.—*Adv.*

DISEASES OF COMMON INTEREST TO THE DENTIST AND OTO-LARYNGOLOGIST

By RICHARD TRAVIS ATKINS, M D, NEW YORK, N Y

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania New York November 30 1931

THE dentist and oto-laryngologist are interested alike in many of the diseases which affect the oral cavity and upper jaw. There are also affections of remote structures in the oto-laryngological field which are of dental origin.

A great deal has been written about these various conditions, and I hesitate therefore, to add another paper which will fail to present anything new.

My remarks will be limited to a brief clinical discussion of the common diseases that our specialties are called upon to diagnose and treat.

The oral cavity is the site of the early manifestations of some of the contagious diseases, with which we should be familiar. The Koplik spots of measles which appear on the buccal mucous membrane and gums opposite the molar teeth, the strawberry tongue of scarlet fever, the occasional appearance of vesicles on the tongue in chicken-pox, and the presence of a membrane on the soft palate in some cases of diphtheria should always be kept in mind as characteristic lesions of these diseases.

Vincent's Infection is commonly encountered by our specialties, and it is interesting to note that the disease was first described by a dentist named Miller.

It is a serious disease, occasionally proving fatal. It is easily transmitted through kissing and the common use of eating and drinking utensils. It frequently follows slight trauma, such as vigorously cleansing the teeth in the presence of infection, and is predisposed to by smoking.

The disease most frequently originates in the gums, but the tonsils are also a common site of the infection, as the crypts harbor the micro organisms where they may remain dormant for long periods of time.

A sore, foul mouth or throat is the chief complaint. Ulcerations of the mouth, tongue or throat with a dirty grey membrane and enlarged sometimes tender cervical lymph nodes are the objective findings.

The diagnosis is made by the presence of the

bacillus fusiformis and the Spirochetes of Vincents in the smear.

Difficulties may sometimes be encountered by confusing this infection with diphtheria and syphilis. In prolonged, severe cases a Wassermann test should always be made, and also, a complete blood examination as Vincents infection is sometimes associated with gangrenous mouth lesions that occur in leukemia, agranulocytic angina and pernicious anemia. The rapidly fatal so called septic pharyngitis may be mistaken for a Vincents infection, although the streptococcus pyogenes is the micro organism usually found.

The fatalities are probably due to secondary infections.

The treatment of Vincents infection depends upon the severity, location and extent of the pathology. As the infection is due to an anaerobic micro organism, cleansing treatment is very essential. Removing sloughs and applying an oxidizing agent to the base of the ulceration will go far towards a cessation of the infective process. Various germicidal preparations are now being used with fair success.

Early diagnosis, vigorous and persistent treatment, and prolonged observation is essential to a cure.

The co operation of the dental and medical professions, propaganda concerning the transmissibility and seriousness of the disease; and the isolation of the infected patients will help to control the disease.

Thrush is sometimes seen by the dentist and oto-laryngologist, although the internist or pediatrician are usually called upon to treat this oral disease. It is occasionally mistaken for diphtheria or Vincents infection. The characteristic discrete, milky white patches, without an inflammatory areola, in the mouths of unhealthy infants make the diagnosis fairly certain. It can be confirmed by microscopic examination of a piece of the membrane, which will show the presence of a fungus, *odum albicans*. It is usually quite easily controlled by mild antiseptic treatment.

Noma or Cancrum Oris is a disease of childhood which often follows some infectious disease. It is characterized by the rapid formation of a gangrenous area on the cheeks or gums, which spreads to the surrounding tissues. It produces a severe toxemia and is frequently fatal.

In its early stages it may simulate a Vincents infection, and frequently the spirochetes and fusiform bacilli are found in great numbers in smears from the lesion. Heroic local, and general treatment is indicated.

Another very serious disease which comes within our province is Ludwig's Angina. It arises from streptococcic infections within the floor of the mouth, which produce a diffuse suppuration of the tissues above the mylohyoid muscle.

It demands prompt surgical relief before extension carries the infection downward through the lymphatic structures producing an edema of the glottis or a mediastinitis. Pneumonia and general septicemia may also complicate the disease.

General anesthetics are absolutely contraindicated in making the incision for drainage, as death frequently follows the first inhalation.

Pemphigus of the mucous membrane of the mouth is a rare disease. It is characterized by the formation of blebs, followed by irregular macerated, frequently bleeding ulcerations. The diagnosis is difficult unless accompanied by dermatologic lesions.

Leukemia may produce mouth symptoms such as swelling and ulceration of the mucous membrane of the gums and palate accompanied by bleeding. A blood examination will establish the diagnosis.

Leucoplakia is quite frequently seen in the mouths of excessive smokers. It is characterized by the presence of a dry white patch usually located behind the molar teeth or along the border of the tongue.

Local treatment is contraindicated. Elimination of the cause, usually cures the disease, but, if it persists or progresses, it must be viewed with suspicion and removed surgically.

Cancer of the mouth very often arises from mechanical or dental irritation, and we should be keenly alive to the early manifestations of this dreaded disease. Owing to the wide publicity that has been given to the "early recognition of cancer," the public has been aroused to seek advice with less delay than formerly.

They have been taught to look upon any prolonged irritation, ulceration, pain, swelling or bleeding with suspicion, and it is the duty of the dentist and laryngologist to examine these patients very carefully with the view of determining whether their fear is justified. Many people have been frightened by the propaganda and it is our duty to allay their fears if there is no evidence of malignancy.

On the other hand, we should not temporize

with suspicious lesions, particularly if the patient is of the cancer age.

Cancer of the mouth is not hopeless, as irradiation combined with electro-thermic procedures is often curative, if used early enough.

Tuberculosis of the mouth is so typical that once seen it can hardly be mistaken for anything else. The mucous membrane is anemic and studded with grey or yellow tubercles. The tubercles break down and ulcerations are formed which are worm-eaten in character. It is usually accompanied by a cervical adenitis. Lupus is sometimes mistaken for tuberculous lesions, but it is differentiated by having points of ulceration and cicatrization side by side. It is usually associated also with lupus of the face.

Many of the manifestations of syphilis occur in the mouth. The most common lesions are the mucous patches of the secondary stage which are often found on the soft palate, lips, gums and sides of the tongue. The primary lesion or chancre may be located on the lips, tongue, palate or tonsil. Tertiary lesions involving the jaws may also present changes in the structure of the mouth.

The salivary glands are occasionally the seat of infection introduced by way of the oral cavity, through the excretory ducts. Foreign bodies and calculi may cause an inflammation of the ducts with subsequent enlargement of the glands.

The pharynx, naso-pharynx and larynx may be involved directly or indirectly through dental affections.

Chronic laryngitis may be due to any inflammatory or ulcerative process in the mouth.

The irritation of erupting teeth or caries of the teeth is said to be an etiological factor in hypertrophy of the tonsils.

Tonsillitis and pharyngitis may result from dento-alveolar abscesses.

It is also well to remember the importance of dental hygiene as a preliminary to operative procedures on the throat, as complications are less likely to occur with a clean mouth.

Nasal obstruction is very often due to deficient and irregular development of the superior maxillary bones. The orthodontist and rhinologist should work hand in hand in these cases to obtain the best results.

Abscess of the nasal septum may occur as the result of an infection traveling through the floor of the nose from a central incisor.

Maxillary sinusitis is of great interest to the dentist because it is so frequently the result of dental disease.

Dental caries of the floor of the sinus is a common cause. Patients with this condition very often consult the rhinologist first, because their symptoms are chiefly nasal. There is a discharge of fetid pus from the nose and an absence of pain. In this connection it is well to remember that pain in the teeth is usually asso-

ciated with acute maxillary sinusitis of nasal origin.

Lipiodol roentgen pictures of the maxillary sinus will sometimes outline a fistulous tract leading to the diseased teeth.

The treatment consists of a removal of the offending tooth, supplemented by irrigations of the sinus.

A certain proportion of the cases of maxillary sinusitis are undoubtedly of dental origin where there is intervening (macroscopically) sound bone between an abscessed root of a tooth and the floor of the maxillary sinus. These patients present all of the characteristic signs of a dental infection, and if sections of the bone were examined microscopically they would probably show the pathway of infection.

Maxillary sinus infection may also follow the opening of the sinus by extraction of teeth. These infections usually clear up quite promptly after irrigation.

Infected dental cysts may rupture into the maxillary sinus and cause a suppurative sinusitis, but this is a rare occurrence.

Serious complications may arise from dental infection of the maxillary sinus; the most common is orbital abscess which may be produced by an osteitis following dental caries.

Cavernous sinus thrombosis; meningitis and brain abscess may also occur by extension of the infective process to the intracranial structures.

Maxillary cysts may be of dental origin. There are two main types—the root or periosteal and the follicular or dentigerous.

The rhinologist very often sees the root cysts. They are inflammatory in origin and comprise about 75% of all maxillary cysts.

The diagnostic sign is a protrusion of the anterior wall, with a crackling-like sound of palpation, if they are large.

Small cysts are usually undiagnosed, unless accidentally discovered by roentgen examination, and they require no treatment except they produce symptoms.

Cysts may be removed through the canine fossa, especially if they are small, and the cavity allowed to cicatrize.

If the cyst is large a Caldwell-Luc operation should be performed and a large opening made in the inferior nasal meatus, thus converting the

maxillary sinus and cyst into one cavity.

Malignant growths of the maxillary sinus sometimes are of dental origin. They may arise from the epithelial structures of the teeth, or degeneration of a dental maxillary cyst.

Very often one of the first intimations of trouble is a toothache, followed by swelling of the adjacent soft parts, which does not subside. Removal of the tooth does not relieve the pain and the tooth-socket is apt to be filled with granulations which bleed easily.

The bony walls of the maxillary sinus are softened by the disease, causing a protrusion in the mouth and cheek. Secondary infection may occur and obscure the diagnosis.

A review of the histories of thirty cases of malignancy of the maxillary sinus, treated on the oto-laryngological service of Bellevue Hospital showed five that were undoubtedly of dental origin.

The treatment consists of a radical removal of the growth, followed by irradiation.

Osteomyelitis of the superior maxilla sometime, occurs, particularly in infants, which results in a loss of considerable bone and tooth buds. These infections are usually very severe and are of staphylococcal origin.

The ears may be reflexly or secondarily involved through dental diseases. The otologist is frequently consulted because of pain in the ear, which is due to caries of the teeth. Noises in the ear and dizziness may also be caused by diseased or impacted teeth.

Auditory neuritis characterized by impairment of hearing for the high tones may sometimes be relieved by removal of dental infection.

Pain in the various ramifications of the fifth nerve is a symptom which is of common interest to the dentist and oto-laryngologist, and very often the cause of the pain is not found in spite of careful examination. Teeth are removed, and operations performed on the paranasal sinuses without beneficial effect. Finally the patient becomes a chronic sufferer, and often is classified as a neurotic.

It is with this type of patient particularly that the dentist and rhinologist should work together, and hesitate before doing any operative procedure that may perhaps obscure the original etiological factor.

DISEASES OF COMMON INTEREST TO THE DENTIST AND THE OPHTHALMOLOGIST

By WM. F. C. STEINBUGLER, M.D., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

THE object of this paper is to demonstrate the relationship between some of the more common dental and eye conditions. That such a relationship exists has been known for

centuries. During the past 20 years the subject of dental focal infection has received much attention, due, primarily to Sir William Hunter, of Montreal, who first called attention to it in 1910,

and to the experimental work of Dr. E. C. Rose-now, of the Mayo Clinic, and the clinical work of Dr. Frank Billings. The last named has defined focal infection as a metastatic, systemic or local condition due to infectious micro-organisms or their toxins carried in the blood or lymph stream from a focus or foci of infection. A focus of infection is a localized or circumscribed area of tissue containing pathogenic micro-organisms and may be either primary or secondary. Clinically, these cases show a low grade anemia, a slight leucopenia with relative lymphocytosis, a low neutrophile count, low blood pressure, slow pulse, low basal metabolism, subnormal temperature and low blood calcium content.

Dental Causes of Eye Conditions—What are the dental causes giving rise to eye conditions, infectious or otherwise? The most common may be grouped under three headings: (1) Pyorrhea Alveolaris; (2) Caries; (3) Apical or Periapical Infection, usually in the form of granulomas of the roots. These consist of a capsule enclosing granulation tissue filled with streptococci, either hemolytic or belonging to the viridans group. The latter is the most frequent and most important. Whether pyorrhea itself is a source of infection is still a debated question. Finnoff, of Denver, considers it the most frequent cause of ocular lesions, while Lawler, of England, is opposed to this view. He bases his opinion on the fact that careful treatment of the mouth has failed to exert any favorable action upon the ocular condition. Another argument which would lend support to his contention is that if pyorrhea is as prevalent as it is supposed to be, there should be many more cases of ocular infection seen.

Periapical tissues are infected: (1) by the passage of bacteria and their toxins through the apical foramina of a tooth, with an infected pulp, consequent on caries as a general rule; (2) by their passage from an infected periodontal membrane via the blood or lymphatic drainage of this structure, and (3) by their passage in the blood or lymph circulation from more remote parts.

The most dangerous forms of dental infection are those of the pulp—pulpless teeth and apical abscesses. They are free from symptoms and hence unsuspected. Being situated in the osseous tissue, no expansion can take place, and their only drainage is into the circulation. They are exposed to pressure transmitted by the teeth during mastication, and as each bite has a pressure of 70 pounds to the square inch, it can readily be seen that a great number of bacteria are forced into the blood stream.

Impacted and ectopic teeth may, at times give rise to inflammatory conditions of the eye, the infection being hematogenous, but, as a general rule, they produce reflex disturbances.

As to which organisms are responsible for dental infection the following conclusions of Bulleid,

based on a bacteriological study of over 800 extracted teeth, and published in the *British Dental Journal*, January to March of this year, seem to sum up the situation:

(1) A member of the streptococcus group has been found in every case.

(2) In a fair percentage of cases, a yellow staphylococcus was present.

(3) The commonest type is the non-hemolytic streptococcus, followed fairly closely by the viridans group.

(4) The presence of true hemolytic streptococcus is rare—seen mostly in the acute alveolar abscess cases.

(5) No specific organism can be determined either by aerobic or anaerobic methods.

Other bacteria which occasionally act as causative factors are pneumococci and micrococcus catarrhalis.

The exact mode of eye infection from a dental focus is still open to question. Benedict of the Mayo Clinic claims there may be: (1) Direct transmission through bones; (2) Direct extension of the process along the periosteum invading the orbit; (3) Transfer by the blood stream. The latter he regards as the most common form. In some cases the infection spreads directly from the diseased tooth to the eye along the nerves. This is so in the case of herpes virus, spreading from the first to the second branch of the trigeminus. The lymphatics undoubtedly also play a role in transmission.

Eye Conditions—What are the eye conditions set up as the result of dental infection or irritation? There is no definite ophthalmic picture that can be attributed to dental infection and any part of the eye may be affected, but the iris, ciliary body and chorioid are most frequently involved. In these locations there is a gradation from an abundant to a scanty supply of blood and hence a gradation in the supply of available oxygen.

McCallan, in a symposium on eye conditions due to focal sepsis, reported in the *British Medical Journal*, December, 1930, classifies them under three headings: (1) Those which might be cured—increased lacrimation, chronic conjunctivitis, ulcers of the cornea, iritis; (2) Those which might be helped—the exudative form of chorioiditis, progressive myopia, thrombosis of the retinal vessels; (3) Those which are not helped—cataract, glaucoma and detachment of the retina.

Of the first group, increased lacrimation is recognized by the persistent tearing, chronic conjunctivitis by the redness of the lids with the accompanying complaint of dryness or burning. Ulcers of the cornea are associated with extreme pain and redness and the most frequent variety belongs to the dendritic group. Here the extension is along the nerve as the different branches of the 5th are affected. Iritis shows itself in the form of a red eye, with considerable tearing and severe pain, which is usually deep seated and

worse at night. It is probably the most common form of eye trouble due to dental infection. Pain in the eyeball and beneath the eye without any other symptom—reflex conditions—may be due to dental infection, very often a pulpitis. Of the remaining conditions, the diagnosis can be established only by the use of the ophthalmoscope, but any case in which there is sudden and marked diminution of vision may be due to dental sepsis.

That dental infection is frequent in ophthalmic practice can be seen by a study of the following figures. Lang found 71 of 176 cases, or 40 per cent, due to this cause. Brown and Irons, in reporting on 100 cases of iritis in 1916, 16 per cent, in their second series of 100 cases reported in 1923, 9 per cent. Frederick, 200 cases of iritis, 37 per cent. Back, 50 cases of iridocyclitis, 32 per cent, the condition in only 4 in this series being definitely negative regarding dental observations. In this study all cases in which the patients were suspected of having syphilis or tuberculosis were excluded. Byers, 80 cases of iridocyclitis, 32 per cent. Butler, 100 cases of uveitis, 12 per cent. Benedict, 60 cases of retrobulbar neuritis, 23 per cent. Elsching, 28 cases of iridocyclitis, 42 per cent. Wendt, 35 cases of iridocyclitis, 40 per cent, only 3 in this series had normal teeth, and Bulson, 100 cases of iritis taken from his private practice, 32 per cent. The French ophthalmologists, Rachen DuVigneaud, Morax, von Lint and Moreau, at a special meeting of the society to discuss this question considered the American concept, especially as to frequency, rather exaggerated.

In only one of the foregoing series that of Back, was the relationship of the side of the dental infection to that of the eye tabulated. In 23 cases of unilateral iridocyclitis 8 showed dental infection on the same side, 4 on the opposite side and 11 on both sides. In 23 cases of bilateral iridocyclitis, 9 showed unilateral infection, 14 bilateral. In 4 of the 8 cases in which the infection occurred on the same side the infection was in the upper jaw, in 2 in the lower jaw and in the remaining 2 in both the upper and the lower jaw. The conclusions reached from these observations are that the infection is usually on the same side and that the upper jaw is responsible for more infection than the lower. This is probably due to the fact that caries involves the upper teeth more than the lower.

As compared with other foci dental infection ranks first being followed by the tonsils, intestines, sinuses, and the genitourinary tract in the order named. Gill of Richmond claims that oral infection is eight times as frequent as tonsillar infection.

Treatment—Regarding the treatment of these cases. When a dental infection is suspected in addition to the local treatment for these conditions such as atropine instillations, leeching, administration of sodium salicylate etc., careful

search should be instituted at once, the x-ray being used at all times.

As to its value, Bullard concluded that in teeth the roots of which have been filled, those most likely to show radiated areas are the ones with what might be termed good root filling, i.e., filling right to, or nearly to, the apex. Those teeth most likely to show no typical shadows in roentgenograms are the ones with no root fillings or only partially filled roots. The only extracted teeth that showed granulomas were those with no root fillings or only partially filled root canals.

Haden made a study of cultures obtained from the periapical tissue of 1,307 vital and pulpless teeth and compared them with roentgen observations. The technic employed provided (1) proper controls to determine the chances of error, (2) a medium which is exceedingly favorable for the growth of the organisms usually encountered and (3) a means of measuring the extent of infection by determining the number of bacteria in the tissue culture.

Of 392 vital teeth, 9 per cent showed from 1 to 10 colonies in a dip agar tube, 5 per cent, 10 or more colonies and only 1 per cent more than 100 colonies. Of 490 pulpless teeth, with negative roentgenograms, 10 per cent showed from 1 to 10 colonies, 60 per cent had 10 or more colonies and 44 per cent had more than 100 colonies.

As a result he concluded that the incidence of infection is almost as high in the group with negative roentgen observations as in those with positive results. There is a sharp limitation to the translation of roentgenologic evidence of infection into terms of bacteria. The absence of roentgenologic evidence of infection at the apex of a pulpless tooth never excludes the presence of active infection. In many cases the roentgenologically negative tooth is a far greater source of systemic infection than the roentgenologically positive one, since in the former there may be little resistance to the infection.

There is a wide diversity of opinion regarding the use of vaccines and their value from the clinical standpoint. Lanier, in reporting on a series of patients with infective diseases of the eye found that he obtained more favorable results from the injection of stock vaccines or serums, both specific and paraspecific products having been employed. Wever expressed the opinion that streptococcus vaccines should always be autogenous and that in general autogenous bacterins are to be preferred to the stock preparations. The best results have been obtained when the pus has been recultivated and fresh bacterin prepared every two to four weeks. In cases of iridocyclitis cultures may be made from the aqueous and the vaccines prepared from these have given excellent results.

Rosenow has obtained favorable results from the use of vaccines prepared from the cultured strain but warns against expecting too much from

the use of specific vaccines or serums since the diseases that are commonly the result of focal infections are usually due to streptococci, immunity to which is of short duration. In a small series of cases in which vaccines were employed, he reported 26 per cent improved, 46 per cent unchanged and 28 per cent worse, compared with 21 per cent improved, 32 per cent unchanged and 47 per cent worse, in cases in which no vaccines were used. Berens was of the opinion that patients who were treated with vaccines made from organisms to which they were particularly hypersensitive were more benefited than those treated with autogenous mixed vaccines, but 19 patients were treated with stock mixed catarrhal vaccines for control and the results compared with 19 treated with selected autogenous vaccines. The results were identical, and he concluded that the nonspecific factor is extremely important. Benedict and de Schweinitz both reported gratifying results from the use of autogenous vaccine.

The histories of two illustrative cases are briefly cited. K. F., single, female, aged 35, first seen June 25, 1918, complaining of redness and pain in right eye of one week's duration. Had two previous attacks, the first 2½ years before being seen, lasting 8 weeks, the second after an interval of 25 months, lasting 5 weeks. Clinical picture—iritis right eye. Wassermann negative. July 1, 1918, right upper first bicuspid removed. Nose condition present which was cleared up. Improvement. July 9, 1918, fresh infection, August 12, 1918, some more teeth extracted. Slight re-

currence in same eye January, 1920. Three more teeth extracted. Patient has remained free of iritis since—a period of 11½ years.

C. W., colored boy, aged 18, first seen April 14, 1931. Had been under treatment in Richmond, Va., for six months prior to his coming north. Vision right 20/50; left 20/200. Both corneae involved in ulcerative process. Cervical glands enlarged. Lids markedly reddened and swollen. Wassermann negative. Because of his race and the glandular involvement, tuberculosis was suspected and he was given tuberculin injections. During the course of the treatment there were numerous recurrences until the later part of July, at which time several teeth were extracted, and the tuberculin injections stopped. Over a period of four months his eyes have remained free of inflammation and his corrected vision is approximately normal in each eye.

In conclusion, focal infections, of which those due to the teeth form the largest group, must be considered as etiologic factors ranking in importance next to syphilis and tuberculosis. When a suspected focus has been removed and a rapid and marked lessening of the inflammation does not set in within forty-eight hours, the true cause has not been reached and a further search should be made. While as a general rule, conservatism should be practiced regarding the extraction of teeth, it should be borne in mind that in doubtful cases, the eye should be given first consideration and elimination of oral sepsis should take precedence over preservation of the teeth.

SOME ORAL SURGICAL PROBLEMS OF INTEREST TO RHINOLOGISTS

By GEORGE M. DORRANCE, M.D., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

AFTER considerable thought, I have decided to limit my presentation today to three subjects of interest to rhinologists, surgeons and dentists, *viz.*, Diseases of the Antrum of Highmore; Adenomas; and the velopharyngeal mechanism of opening and closing in cleft palate.

My hope is to start a discussion from which we will all benefit.

Antrum: Subject No. 1. The antrum of Highmore, because of its situation has been the subject of intensive study by both rhinologists and dentists.

While conflicting views have naturally arisen as to the etiology, pathology and treatment of the various diseases visited upon the antrum, the results of the controversy has been of inestimable value to the patient and doctor. The surgery of the sinuses cannot be standardized, but working outlines can be used and are helpful.

In treating the various inflammations of the

antrum we find an almost universal agreement among rhinologists, oral surgeons and dentists.

When I discuss the treatment of multilocular cysts and cleft palate, I realize I will be in a field where wide diversity of opinion exists.

The antrum of Highmore is a pyramidal air space located within the body of the superior maxilla. It is lined with mucoperiosteum the same being a continuation of the lining of the nasal chamber. It is covered with ciliated columnar epithelium and the cilia move toward the hiatus semiluminaris which you know is beneath the middle turbinate bone. Fluid cannot drain out of the antrum unless the head is held downward and to the opposite side. At birth the sinus is very small, but by the 12th or 13th year it reaches its full development—the adult size varying considerably. The roots of the molar teeth, the bicuspid and not infrequently the cuspids are in close relationship with the floor and not rarely

one or more tooth roots produce elevations in the floor of the sinus. It is generally conceded that all infections of the antrum arising from infections of the periodontal membrane and the surrounding bone at the apices of the teeth lying adjacent to the antral wall should be taken care of by the dentist or oral surgeon. All other varieties of antral infections as well as inflammations of the other nasal sinuses are in the field of the rhinologist.

While acute antrum infection is rarely a complication of periapical infection it does occur. It is estimated that 20 to 40% of subacute and chronic maxillary sinusitis are primarily due to periapical tooth inflammation.

In the acute or subacute stage of antral infection resulting from tooth infection, the proper procedure is to drain the antrum cavity through an opening, made above the tooth. If chronic inflammation is present, permanent drainage of the dependent part with removal of all diseased tissue is essential. This permanent drainage should be secured by an opening through the nose.

Symptoms of Antral Infection: In the acute stage, there is fever and leucocytosis; almost invariably there is pain and tenderness over the antrum; referred neuralgic pains are common; giddiness and vertigo are almost constant factors. Nasal examination will often show local patches of pus at the orifice of the sinus. Irregular discharge of fluid or pus from under the turbinates may occur. X-ray and transillumination will show a blurring of the sinus shadow. A good x-ray picture is almost diagnostic in itself.

The diagnosis can always be made by penetrating the antrum, under local anesthesia, either through the nasal wall under the middle turbinate or through the canine fossa.

Treatment: I do not think that tooth socket drainage is satisfactory. Even if the tooth is to be extracted, I rarely drain through the socket. The best way to obtain drainage is to drill an opening 5 to 7 mm. in diameter just above the apex of the infected tooth. Local anesthesia should be employed.

The cavity should be irrigated twice a day until all signs of suppuration disappears. In all chronic antral infection, I use the Denker or Sluder operation. I do not advise curettage of the walls but do remove any polypi, dead bone or coarse granulation tissue present.

I have been asked what route would I take when a broken tooth or root has been pushed up into the antrum and a chronic infection has resulted. If the nasal conditions are normal, I would use the oral route using the method advocated by Dr. Theodor Blum, *viz.*, an incision through the mucous membrane and submucous tissue down to the bone on the buccal side in the molar region parallel to the free gingiva and about 0.05 cm. above it until the region of the first premolar is

reached. Then it is carried upward toward the apex of the canine. The flap is elevated and a thin plate of bone is removed from the canine fossa. In this way, free access is given to the sinus; irrigation can be carried out and the flap may be sutured leaving adequate bony support on its convexity.

Adenomatoma: Subject No. 2. I am now going to discuss the subject of adenomatoma—frequently referred to as multilocular dentigenous cyst—less frequently called adenocarcinomata. It is a neoplasm of the jaw originating from the enamel organ or the periodontal epithelial debris. It is, as a rule, a multilocular cystic growth with epithelial cells lining the cyst walls. Cystic degeneration may or may not occur in the centre. If it does not, we have a solid growth frequently mistaken for some other variety of tumor.

If the tumor is sectioned, we find a bony wall encasing a cystic or solid growth. The cyst may be unilocular or multilocular and usually contain a yellowish-brown fluid. Inspissated fatty material, gritty substances and often imperfect enamel are present. The walls of the cysts may be lined with papillary projections; bony or fibrous trabeculae traverse the growth. On section the solid portions resemble medullary carcinoma. Under the microscope, we find a variety of epithelial cells, stratified squamous and columnar enameloblasts predominating.

These tumors may occur at any age but the vast majority reported occur in early adult life and women are more prone to have them than men. A careful history will reveal the fact that practically all these tumors begin shortly after full growth of the permanent teeth.

The growth is characteristically slow. In untreated cases, ten to thirty years may have elapsed from the time the growth was first noticed. In the beginning we find a slight enlargement of the alveolar margin; the outer table, being thinner than the inner, is more affected. Teeth in the immediate locality are loosened or displaced. As the growth continues the characteristic egg shell crackling can be felt. Adenomatoma involving the upper jaw because of the anatomy of the parts is a much more serious problem. In the late cases they involve the antrum and may if untreated encroach on the orbit or nasopharynx. In this paper, I am only discussing the cases involving the upper jaw. Most authorities state these tumors are locally malignant but rarely or ever involve the lymphatics or metastasize. This is not my experience. I feel all these cases are potentially malignant and should be so treated from the start.

Treatment. Complete excision. If the antrum is involved we make no attempt to preserve it—we do not hesitate to excise the entire half of the upper jaw just below the orbit if conditions warrant it. Our belief is that every particle of this tumor must be removed just as much so as when

dealing with an adenocarcinoma of the parotid. All structures which prevent the accomplishment of our goal must be sacrificed.

I have under my care at the present time a man dying of metastasis to the spine upon whom the first operation for a multilocular cyst was performed 15 years ago. I operated upon him 10 years ago and reported him as a complete cure 7 years later. It may be said he has had fifteen years of life by conservative treatment. Yes, but he could have been cured by a complete excision and in the early stages a mutilating operation would not have been necessary either.

I am certain that the conservative treatment practised is wrong. It is easy—non-mutilating and the patient will go elsewhere for his recurrence—but it is not good surgery.

My advice is—treat all cases of multilocular cysts as malignant cases—knowing that complete excision in these cases means more permanent cures.

Cleft Palate—My last subject to-day is cleft palate of which I will only briefly speak. It certainly is of interest to rhinologist, oral surgeon and dentist.

I am convinced that until we all realize that cleft palate cases are not properly treated unless we restore proper speech function, we shall not make further progress in our operative procedures.

I do not think minor postoperative procedures are of much value in helping speech. I refer to turbinectomy, removal of tonsils, straightening of teeth, etc. Unless adequate velopharyngeal closure has been accomplished, by this I mean closure of the opening between back part of the mouth and the nose, the operation is bound to be a failure regardless of the anatomical result obtained.

All workers in cleft palate surgery have felt the necessity of obtaining some method of lengthening the palate, but until we devised the "push-back" operation none of the procedures were practical.

The reason for this is simple. They failed to realize that the palatine attachment of the levator palati muscle is placed too far anteriorly and the tensor palati muscle is shorter in all cases of insufficiency of the palate, as a result no matter how much the levator palati muscles pull they could not bring the velum into its normal position and secure velopharyngeal closure.

Unless after freeing the palatine mucoperiosteum, you divide the fan-shaped portion of the tensor palati inserted into the palatine aponeurosis you cannot get sufficient backward displacement and unless you do, velopharyngeal closure is impossible.

Naturally I favor the "push-back" operation in all cases of short cleft palate, be the shortening congenital or post-operative. I do not say it is the last word in cleft palate surgery. Unquestionably it will be improved; but at the present time it is a valuable measure in restoring the normal speech.

Rhinologists and oral surgeons have not realized that there is a circular sphincter between the nasopharynx and oropharynx which acts the same as any other circular sphincter muscle in the body. Like all other sphincter muscles, it is formed of one muscle being the uppermost portion of the superior constrictor. The anatomists have described the superior constrictor as arising from one hamular process, going around to the opposite hamular process. They have missed the main feature. Examining a palate of a patient who has lost the nose and part of the turbinate bones made it possible for me to see this muscle close in this circular manner. Even light or air will not pass through when it is closed. The old idea was that this closure was brought about by the palate being drawn back and grasped by the superior constrictor muscle. I do not know where this idea originated but it is not correct. I had no conception as to how a cleft palate should be repaired until after I realized the correct insertion of this muscle and the correct physiology of this closure.

I have some slides with me to show you where this muscle is inserted. If I can convince you that this superior constrictor muscle is a circular muscle and produces this complete closure, I will be able to correct this false information which has been published in the textbooks.

The simplest of cleft palate cases is a simple division of the velum. In my series, this gave the worst speaking voice. I can easily understand the reason for this with the knowledge I now possess. It is possible now to correct some of these short palates by means of the "push-back" operation. By this, I mean we can improve the speech range about 40%. Undoubtedly, as time goes on, we shall be able to improve it more and more.

THE RELATIONSHIP BETWEEN DENTISTRY AND RHINO-

By LESTER RICHARD CAHN, D.D.S., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, N. Y., December 15, 1934.

ANYONE practising dentistry must constantly observe the close relationship between the diseases of the teeth and mouth and those of the nose, throat and ear.

The rhinologist's contact with oral disorders is mostly through inquiry as to the possibility of the teeth causing maxillary sinusitis. Many varying percentages have been compiled concerning the number of cases of antritis due to infection arising in and about the teeth. Skillern states that "it was formerly thought that every case of antral empyema was directly due to dental infection. This opinion gradually changed until now the relation is placed at approximately 20%." He then quotes statistics ranging from 100% to 8%. Probably the lowest figures are the truest. As far as my personal observations are concerned I rarely ever find the teeth responsible for maxillary sinusitis. Frequently upon extracting a molar it will be found that one root has penetrated the floor of the antrum. This tooth may have been pulpless for years and consequently badly contaminated and infected and if no probing is attempted and the mouth of the socket protected from food and debris by a light gauze packing, no trouble will follow. I saw a case of acute alveolar abscess in which the pus had entered the antrum and was discharged through the nose, yet after the abscess was incised and the dental focus drained the whole condition subsided without any subsequent antral trouble.

Occasionally extremely large cysts are encountered where the floor of the sinus has been displaced so far upward as to almost obliterate it and yet it has remained uninvolved.

On the other hand, we not infrequently see cases in edentulous or semi-edentulous mouths where the floor of the antrum is almost on the alveolar ridge. Roentgenograms of this condition may resemble a cyst and such a false diagnosis has led to infinite trouble. Upon removing a loose upper bicuspid I encountered a large cavity in connection with the tooth. There were no teeth distal to this one. There was a mass of granulations about the root, a condition commonly associated with pyorrhea. Unfortunately no roentgenogram had been made before the extraction because the tooth being loose no operative difficulty was expected. Some of the granulation tissue was curetted and an x-ray taken, but this left me in some doubt as to whether I was dealing with a low antrum or a cyst, Fig. 1, and I therefore made sections of the curettings. These sections revealed glands, Fig. 2, among the inflammatory tissue indicative that the Schneiderian membrane had been attacked and I realized that I was

in the antrum. No further tempted and the wound healed. Histological examination of the cavity might still have been made and an attempt made to remove the patient's disadvantage.

This case is interesting for three important facts. One, a tooth no matter how simple seem without a roentgenological examination of all should be made regardless as to whether or not. Examination of the set up an obscure condition as Three, here was a tooth sinusitis which was directly sinusitis ever developed removal.

As far as treatment of concerned I am convinced alone is capable of its proper there is an oral cause for it was stated before does it should be eliminated by the geon. It is also wise in need to seek for such a cause, the rhinologist and stomatologist the responsibility for the hal- lons to the former.

Furuncles and abscesses are sometimes of dental origin caused by direct extension of contiguous area as in the case or they may be due to a focus of oral origin. The two illustrative.

Case 1.—A patient had recurrent furuncles in the These boils were lancet obtained for a time. dental examination the were found discolored vitality of the pulp, a copious discharge of pus instead of pus in the gum, as in the tive osteitis, of the nose, the nasal floor place, anal- this was the dent; has been Ca- pid it uns

sufferer from nasal furuncles and that since the tooth had been removed the condition had been entirely relieved and had remained so up till the present, a matter of nine years.

FIGURE 1

From this radiograph it is difficult to tell whether one is dealing with a low antrum or a cyst. In this instance a radiograph of the opposite side was of little help because the teeth were present.

A knowledge of the diseases of the oral mucosa can be jointly shared by the dentist and the laryngologist. The pathology and treatment of the fuso-spirillary infections are the same for the mouth as they are for the throat. However, I believe that the omnipresent diagnosis of Vin-

FIGURE 2

A section made from the curettings removed from the cavity shown in Figure 1. At A we see a gland. The finding of glands in the tissue revealed the fact that we were in the antrum, because there are neither glands in the capsule of jaw cysts, nor in gum tissue.

cent's gingivitis and angina is much overdone. Ulcerative conditions of the mouth and throat are often significant of something more serious than a fuso-spirillar infection. It is wise to have

a blood examination made in all cases of this type as is exemplified by the following instance.

Case 3.—I was asked to see a young married woman who had a small ulceration of the gum directly in back of the lower right third molar. Fig. 3. She had been seen by her family doctor and dentist who diagnosed the condition as a Vincent's infection. A relative of hers, a laryngologist, was also asked to see her and he in turn invited me in consultation. When I saw her her face was somewhat swollen on the affected side and she was having a great deal of pain; her temperature was 102° F. She was in bed but did not seem particularly malaise. She had an ulcerative process distal to the lower right wisdom tooth about the size of a dime which seemed to be spreading to the buccal tissues. I made a smear of the lesion and told the patient to keep up the anti-Vincent treatment for the time being. The smear revealed a great many fuso-

FIGURE 3

A drawing made from the case of ulceration behind the lower molar. This was taken for a fuso-spirillar ulcer (Vincent's infection), and was treated as such for several days before a blood examination revealed the condition as being due to an agranulocytosis.

spirillar organisms. The next day I again saw the patient. There was no abatement of her condition and the ulceration had become much larger, deeper and was spreading rapidly to the inner surfaces of the cheek. I then advised her being sent to a hospital where a blood examination was made and revealed a white count of 1000 with no granulocytes. A diagnosis of agranulocytic angina was then made. Fortunately this patient recovered after twelve blood transfusions.*

Herpetic eruptions of the throat and mouth are also of interest to workers in these fields.

(* Since writing this paper I have learned that the patient had

Their presence is very annoying and their cause obscure. Diet plays a great part in their alleviation. I had a patient who had these lesions for the longest time, and had been seen by physicians and stomatologists without much relief. Wassermann and general physical examinations were negative. When I first saw her her oral and pharyngeal mucosa were stained a bright red and she told me this was due to a treatment advised by a laryngologist. This treatment consisted of painting the small herpetic ulcers with 20% mercurochrome and continually sucking on mercurochrome lozenges. Of course there was no cessation of the condition under this regime. With the discontinuance of the mercurochrome and the establishment of a normal diet to which was added 16 ounces of orange juice daily she became entirely well nor has there been any recurrence in over eight months.

The question of oral sepsis should be of intense interest to every laryngologist. It is inadvisable to ever operate on the throat, unless in an emergency, before eliminating at least the gross mouth sepsis. I believe that this point is too frequently ignored by the majority of laryngologists. Herbert S. Birkett in discussing the preparation of the patient prior to tonsillectomy says: "Should defects exist in the teeth or should the gums be unhealthy, these must first be put right. If any apical lesions be present then these should first be rectified as I have repeatedly found when this is done, although the tonsils may show a co-existing chronic lacunar tonsillitis, the patient had thus got rid of his systemic symptoms."

Oral sepsis undoubtedly plays a great role in malignant diseases of the oral cavity and the throat and certainly should be eliminated before any treatment is instituted. According to Cade: "It is important in all cases of laryngeal and pharyngeal carcinoma to eliminate all sepsis of the mouth before beginning the treatment. All carious or even suspected teeth should be extracted before irradiation." He also finds that there is much less chance of necrosis in edentulous mouths following irradiation for intra-oral cancer.

The dentist and oral specialist are brought in contact with the otologist for two reasons. One is to seek for oral foci of infection as a cause for chronic suppuration of the ear, furunculosis and tinnitus. The other is to find a cause for constant earache.

I believe that most cases of otalgia, where there is no definite cause to be found in the ear, is due to dental disease. It is occasionally brought about by impacted, embedded or mal-

posed teeth but is most frequently due to a diseased dental pulp.

The pathology of the dental pulp can only be considered briefly in this paper. However, it is of interest to note that this small organ is highly innervated and that practically any pathological change within it is liable to involve one or more small nerve trunks causing an interstitial neuritis. Calcification, sometimes wrongly called pulp stones, are commonly found in the pulp and I have demonstrated them engulfing and impinging upon nerves. Local neuritis of the pulp nerves is prevalent and is prone to be reflected as a neuralgia to any area innervated by any branch of the fifth nerve. Sometimes the pain can be localized and sometimes it cannot. The following cases illustrate both the obvious and the obscure conditions.

Mrs. R. suffered from pain in the left ear. The pain seemed to radiate from the lower left third molar. This tooth had a large cervical cavity although the decay did not extend to the pulp. A physician declared the ear to be normal. The tooth was removed and its pulp sectioned. The histological examination disclosed large masses of interstitial calcification. With the extraction of the tooth the pain in the ear disappeared entirely.

In this case there was a distinct reason for the earache. The pain radiated from the tooth and this tooth was diseased. In the next instance, however, the diagnosis was more difficult.

Miss M. had an annoying earache over a long period of time. An otologist treated her symptomatically although there was no apparent disease of the ear. She was finally advised to have her teeth examined. They were found to be in fairly good condition inasmuch as there were no untreated cavities. There was no pain in the mouth and the roentgenographic examination failed to reveal any abnormalities. On the occlusal surface of the lower left third molar there was a fissure that seemed to have some decay. This was opened and found to be superficially decayed. I was not particularly sanguine that this was the cause of her ear trouble. A sedative was placed in the fissure and surprisingly the earache disappeared. The defect was subsequently filled and the patient had had no recurrence of the otalgia.

I have tried to show the close relationship between the mouth and the nose, throat and ear and that an interchange of ideas between practitioners in these fields will do an inestimable amount of good to the patient and add to our common knowledge.

DENTAL CARIES AS AN ETIOLOGICAL FACTOR IN THE TOXEMIAS OF PREGNANCY

By GEO. W. KOSMAK, M.D., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

IN the search for the causes of the general group of disturbances to which the term toxemia of pregnancy has been applied, local foci of infection have been noted among the many etiologic factors included in various lines of research. Arguments have been advanced, both for and against this theory, and while there is still a great deal of doubt as to the actual connection between dental infections and toxemia much evidence has been adduced which points to the probability of this relationship.

It may be of service perhaps to summarize what evidence we have of the relation of pregnancy to disturbances of the teeth. The old assumption of "a tooth for every child" was probably true in former days when the abstraction of calcium salts from the mother by the fetus was a matter unknown. However the clinical fact was recognized that pregnancy did have in many cases a deleterious effect on the teeth and that so-called "softening" was not unusual. A carious process already present might extend and thus lead to further trouble. Permanent dental repair was therefore not countenanced as a general rule, but this idea has been superseded fortunately by the more sensible one that whatever dental work becomes necessary during pregnancy should be carried out within certain limits. This applies particularly to the eradication of foci of infection either in the teeth, or their immediate environment, provided this can be done without stirring up further trouble.

The toxemias, particularly in the latter months, constitute one of the most serious complications of pregnancy. The uncertainty as to whether the condition is a mere derangement of physiologic function; whether it has an underlying pathologic and anatomic basis, or whether we are dealing with an infectious disease, makes it essential to investigate every possible angle of the etiology.

While no satisfactory attempt has been made to isolate a specific organism in explaining the possibly infectious character of eclampsia, various sources for the development of such a process have been described. Among others, we find the suggestion of Talbot, of Boston, who believes that the fundamental cause of eclampsia is not to be sought in the products of conception, but in a focus of infection. He was prompted to this theory by the findings revealed in an x-ray examination of the teeth of one of his cases of eclampsia. Talbot then subjected a series of 97 cases of toxemia to thorough dental examination and claims to have found evidences of chronic sepsis in the teeth of all without a single exception. The presence of a chronic septic process admittedly has a

secondary effect on the kidneys. The toxins of an acute infection produce an inflammatory reaction in the kidneys with an inhibition of their excretory function, which in turn reduces normal elimination. It has been assumed that the symptoms of the toxemia of pregnancy may be caused by the retention of the normal physiological waste products of the developing pregnancy and the retention due to damaged functional power of the kidneys. A vicious circle seems thus to be established;—the toxins of chronic sepsis by their inhibition of the kidney function cause a retention of the normal waste products of the body. These waste products are again injurious to the excretory function of the kidneys when they are present in abnormal concentration in the blood. Nature's endeavor to improve this situation is reflected in the rise of blood pressure which is now generally accepted as one of the earliest evidences of the presence of toxemia. Clearly established cases are on record both in dental and medical literature which demonstrate the good results in cases of arterial hypertension by the removal of foci of infection from the teeth. In fact it has also been reported that certain cases of albuminuria have been cured by the same means.

Talbot has gone even further in this hypothesis by claiming to show that the placental infarct is the result of hematogenous infection of the placental site, dating primarily from a point of absorption in the teeth, or tonsils. Whether this claim will be substantiated remains to be seen, but undoubtedly it calls for further study and observation.

Definite proof of the connection between infectious dental foci and the production of toxemias of pregnancy, particularly those of the latter months, demands further study. However the reasonableness of the theory has prevailed sufficiently to bring about a common acceptance of the direction to keep the teeth of a pregnant woman clean and to take care of all caries and root infections. In fact, examination of the oral cavity has become a routine procedure in antepartum examinations and specific directions to remedy any errors are generally insisted upon. There is no doubt that the restoration of a clean mouth contributes not only to the comfort of the patient but also to her general well-being in preventing the absorption of infectious material and possibly other toxic substances. In addition to caries, diseases and disturbances of the gums should be noted and directions given by every obstetrician to his patients regarding the treatment because of the undoubted satisfactory results which attend this precaution. Unquestionably in

the course of time the pregnant woman will be impressed with the importance of a healthy dental condition, as she has already been impressed with the need of normal functioning kidneys and other organs.

The literature on this subject is not very extensive and much of it is characterized by expressions of opinion and beliefs, but there are a few outstanding contributions in which there is an attempt to produce experimental in addition to clinical proofs. John E. Talbot, as already noted, has made probably the most outstanding and satisfactory references to the association of focal necrosis in the toxemias of pregnancy. Dr. Talbot has submitted very satisfactory clinical evidence from cases in which immediate relief from toxic symptoms resulted after the extraction of definitely infected teeth. However, he believes that the discovery of septic teeth in the latter months of pregnancy does not demand their removal, but, on the contrary, if the tooth is extracted, or even drainage instituted, this treatment may throw more toxins into the system and thereby inhibit the functional powers of the kidneys further, with the result of bringing on convulsions or other serious symptoms. Palliative treatment during this period is indicated but after the end of the puerperium such infectious foci should be eradicated before the advent of another pregnancy.

Another valuable and interesting account of focal infection in eclampsia is that presented by Johnston, Johnson & Nichols (*Texas State Journal of Medicine*, December, 1929). These authors call attention to the finding of tyramine in the blood, vomitus, gastric contents, and urine of an eclamptic patient, and in explaining the origin of this substance believe that it was due to a combination of factors, including the presence of bacteria or their enzymes, acting on certain amino acids circulating in the vascular system of a pregnant woman. It is believed that usually only minute quantities of poisonous amines are formed in the general circulation, but when the amino acids of the blood are in excess, due to the absorption of a recent placental infarct or to the ingestion of a large amount of meat; or to an accumulation of such acids from retention, as in cases of nephropathy, then, provided infection co-exists, amines may be formed in amounts sufficiently large to produce symptoms of toxemia of pregnancy. The authors lay stress on the following points: The placenta is the most plausible source of the toxin; infection is necessary for the production of amines, and kidney dysfunction and the ordinary circulatory handicaps of pregnancy make for a more probable development of the toxemia. They therefore stated that in their belief a *Bacillus coli* infection is present in practically every case of toxemia of pregnancy and in supporting their claims refer to the work of numerous investigators. Furthermore it was noted

that the chemical properties of tyramine are the same as those associated with the circulatory disturbance and symptoms of late toxemias. Actual tyrosine contents of a placenta were determined and from that the possible tyramine content of an infarct was estimated. The amount of tyramine available from a moderately large infarct would be more than ample to produce severe symptoms of toxemia. The influence of focal infection in this process depended upon lowering the general resistance which gave the colon bacillus a better chance to invade the organism. Among the sources of local bacterial invasion the teeth and tonsils may be regarded as the chief offenders and constitute apparently in the theory just referred to the indirect cause of the pathologic process. Naturally the confirmation of other observers is desirable.

Dr. William Kerwin of St. Louis, Mo. (*Jour. Missouri Medical Association*, 1925) believes that pregnancy claims a high toll in teeth expenditure because of the acid saliva which is usually present, and therefore he urges the use of alkaline mouth washes during pregnancy, carefully supervising the diet, prescribing calcium and giving all necessary attention to the teeth during this period.

R. T. LeVake (*Journal-Lancet*, 1916) in commenting on the theory of Young of Edinburgh, that toxemia is due primarily to placental infarcts caused by thrombosis of uterine vessels and consequent concealed hemorrhages, believes that a focal infection is the underlying factor in the production of these lesions. Obstetrical histories rarely contain data regarding dental infections and LeVake truly states that if we found foci of infection in other parts of the body of half the magnitude of many dental infections, they would be constant and insistent sources of anxiety. Positive cultures of streptococci and staphylococci from diseased teeth are not unusual and can lead to further trouble. LeVake in his article presents 13 personal cases of eclampsia in which an infectious process was found.

W. N. Rowley (*Bull. Lying-In Hospital, New York*, 1922) in describing the dental findings in a series of patients, claims that the removal of teeth with peri-apical infections and extensive caries can be safely done during pregnancy, although care must be taken to watch for reactions. McIlroy, Rushmore, Miller and others, including a number of foreign observers have all indicated their belief that dental infections constitute an important rôle in the production of pregnancy toxemias and urge upon the medical and dental professions a closer cooperation in the handling of these conditions.

In view of the evidence on hand, both clinical and pathological, that a probable relationship exists between the toxemias of pregnancy and a focus of infection, further confirmatory experimental study is definitely indicated. Whether as claimed by some, the disturbance is due directly

to the absorption of toxins from the septic focus, or whether the effect is secondary through the involvement of the kidneys or the placenta, is yet to be determined. However, in view of the good results which have attended the assumption that either one or both of these theories is correct, it would be advisable to further the cooperation between the doctor and dentist in such cases. This means that as the doctor sees the patient first, he should include in his antepartum examination a careful inspection of the patient's teeth, and if there is any doubt in his mind, either from the subjective or objective findings, that the dental apparatus is not normal, consultation with a dentist should be had. If discovered sufficiently early in pregnancy the consensus of opinion seems to be that prophylactic dentistry is always effectual. On the other hand, if advanced caries are present, or apical abscesses and other infective lesions are discovered, these must be treated according to accepted standards.

Talbot's observations would lead one to hesitate about eradicating active foci although this

would appear in line with the hesitancy which every dentist displays in extracting abscessed teeth. However it should be possible to reduce at least the absorption from such foci by a variety of palliative measures with which the dentist is necessarily more familiar than the doctor.

There is one other point to be considered by the physician, namely the effect which bad teeth, so-called, have on digestion, whether from a mere inability to masticate properly, or whether bad results do not attend the ingestion of an infected saliva. These are important things to bear in mind in every case and should govern the decision as to how much dental treatment may be necessary. The extraction of teeth should not be done in a haphazard fashion and patients often bewail the rapidity with which extractions were done to the detriment of their mastication and the troubles associated with later artificial teeth. However that need not deter one from insisting that the dental apparatus be put into as good a condition as possible in order to preserve a proper health balance of the entire organism.

THE CONTRIBUTION OF PEDIATRICS TO DENTAL HEALTH

By ROYAL STORRS HAYNES, M.D., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

AS a pediatricist, I may, perhaps, be permitted to wonder whether pediatrics has contributed and is contributing to dental health. It seems to me that until now the initiative towards arousing an interest in dental health and awakening an appreciation of its importance in relation to the general health of the community has been taken almost solely by the dentist. It is natural that this should be so; because the dentist is confronted daily by the results of dental ill-health and has to attempt to combat them from the standpoint of repair and cure. For him there is no escape, no shifting of responsibility possible. But I am sure that the pediatricist can and should contribute to dental health; and I am convinced that he will contribute when once he realizes that it is a part of his function so to do and that all that he is doing toward making stronger and healthier children may be made to serve this cause if he will become, as we might say, "dental health conscious".

It is greatly to the credit of the dental profession that it has stepped out of its antique rôle of curative and reparative dentistry and has taken up both the prevention of dental defects and caries and the building of sounder teeth. The surveys which have been made of dental conditions throughout the country have shown appalling figures. It has

been estimated that of our 45,000,000 children, 95% have dental caries and 85% have defects of occlusion. To take care of this situation, which leaves out of account the adult element of the population who must also be treated, there are, in this country, but some 70,000 dentists. Not discouraged, however, by the impossibility of properly handling this present dreadful situation, Organized Dentistry has set about to investigate the causes which have produced it, realizing that if ever dental defects and caries are to be eradicated, it will be by prevention rather than cure, by the building of healthy teeth rather than by treatment of those persons whose teeth have become affected. So, paralleling the changes which have taken place in the medical profession where the recognition and treatment of disease has yielded in prominence to the prevention of its occurrence, and where the sentiment is toward the idea that the doctor should be a builder of health, in the dental profession, too, its function if filling teeth and correcting mal-occlusion is having added to it the prevention of these ills through an understanding of how they come to exist.

Now there is no one better suited to cooperate with the dentist in the prevention of dental defects and the building of dental health than the pediatricist. He is primarily

and fundamentally interested in producing health in the growing child. His activity covers the ages during which, as a separate entity, the young organism manufactures the teeth which must serve as organs of mastication throughout the life of the individual. His situation is somewhat different from that of the obstetrician. The obstetrician is concerned with teeth more from the standpoint of the preservation of the teeth of the mother than from that of creating good teeth in her offspring. If he supplies the mother with a reasonable diet containing an adequate supply of mineral salts and vitamins; and keeps her free from, or treats constitutional disease, he can be pretty sure that the deciduous teeth of the infant will be well formed. For such is, the so to speak "parasitic" relationship of the unborn child to its mother that a fetus will take what it needs of bone and tooth building material from its mother even if it be at the expense of the mother's own tissues. Quite otherwise is it when the fetus becomes the infant. The infant is passive in regard to his nutriment. His intake of building materials and consequently his strength and vitality depend in large measure upon the directing mind of the pediatricist; and the constitution of his teeth as one of the growing organs of the body will be related to the degree of appreciation on the part of the pediatricist of his responsibility for this element of the child's growth.

The pediatricist realizes how important are good teeth in relation to the general work he does for children. He knows that for a child to grow properly he must have a good nutrition; the child's digestive tract must function properly as well as receive an adequate amount of the proper food elements. Part of the function of the digestive tract is mastication. Mastication implies the use of the jaws and the teeth and a normal dentition is necessary that a child may have a normal digestion, a normal nutrition and a normal growth of the body as a whole. Deviation from a normal dentition from the mechanical standpoint of mal-occlusion may also produce detrimental effects on the bones of the face and jaws, bringing about deformities which interfere with respiration and predispose to infection of the accessory sinuses. The pediatricist is aware that positive harm may come to the child because poor teeth, which become carious, may favor infections, of themselves or of the gums and jaws, which infections lower the child's health, if not actually causing, as they may, disease of internal organs by extension. And his study of some of the common affections to which children are liable has taught the pediatricist that these may affect the development

and the health of the teeth and therefore militate against normal nutrition and growth.

He is therefore conscious of the important part played by the health of the teeth in the health of the child. But I fancy that he has been accustomed for so long to regard bad teeth—and he *must* do so when it is a question of cavities and mal-occlusion which require the attention of the specially trained person—as coming exclusively into the field of the dentist's activities, that he does not always realize how much he can do, himself, to prevent the occurrence of these conditions which he is not prepared to treat. It may not occur to him that the principles of hygiene and dietetics which he commonly applies toward the general health of the child can be directed toward the creation of healthier teeth and the prevention of dental illness if only he will have the teeth in mind when he is thinking about the development of the rest of the body. Nor does he see how the modern dentist who has come to know much about the factors underlying the health and resistance of teeth looks for aid to him—the pediatricist—as a specialist in the realm of nutrition.

For the admirable work by research workers in dental problems during the past decade has shown that the health of the teeth is a question of nutrition. The child with dental caries is a child with imperfect nutrition; and such a child, in the mind of the pediatricist himself, is a child with poor health. The saying "a carious tooth means a sick child" is not greatly an exaggeration.

As pediatricists we are constantly searching for earlier and finer indications of improper nutrition. We are not content to wait for bony deformity or even a "rosary" to reveal to us the condition of rickets, nor for bleeding gums and sub-periosteal hemorrhages to proclaim the existence of scurvy. We use the X-Ray. Now one of the things which dental research has shown us is that the tooth, the only part of our bony system which we can see, is one of the earliest indices of nutritional deficiency and that it is affected by smaller degrees of deficiency than are other and more commonly regarded organs.

The correlation of dental caries, which as we know occurs in such a large percentage of our children, with nutritional deficiency has widened the scope of the effort for child health for it has brought into the pediatric field as subjects for better feeding countless children whom the pediatricist, without the delicate standard of dental health might, on the basis of growth in weight and height, have regarded as coming within the limits of normal. A realization of this can only stimulate the pediatricist to greater activity and to further studies in

the great field of nutrition and in these studies he will find much to enlighten him and extend his present knowledge if he will acquaint himself with the existing dental literature on the subject of the cause and the prevention of dental caries and the effect of diet on the development of the teeth and jaws.

There is not time to enter into detail regarding the dietary elements necessary for the proper development of the teeth. I would like, however, to mention certain salient points.

One is the existence of excellent dentition among races who practice little or no dental hygiene. Sound teeth have been found among peoples on widely differing diets, some preponderantly protein, others largely carbohydrate. The skulls of aborigines of this continent, dying before the advent of the white man and the white man's diet have shown beautiful teeth and jaws. At the present day in Hawaii the usual prevalence of caries is found in these communities which have adopted what might be denominated the American dietary, while in remote districts where the children still have a native manner of eating there is little or no caries. Filipinos coming to Hawaii as adults have sound teeth while their children who eat a good deal of rice and little or no milk have extensive dental decay.

There are qualities in primitive diets which modern methods of food production diminish or destroy. We are largely city dwellers and often far from the source of supply. Our cereals are prepared so that they will keep and often in the milling essential substances are removed. Our vegetables are carried far; we buy them instead of raising them and expense is an element which cuts down the consumption. We produce a great deal of sugar in the refineries and consume it as such instead of making it in our bodies from more complex carbohydrates. We choose muscle meats and scorn the viscera which are preferable. Our food in general is such that it requires very little tearing or chewing which are good for the physical strength of our teeth and jaws. All these factors, commercial economic and esthetic tend to affect our civilized diet toward insufficiency.

A sufficient diet is made up of approximately thirty-five essential substances. About eighteen are digestive products of protein; one is the sugar, glucose; ten are mineral elements; six are vitamins. "So far as we know"—to quote from McCollum—"any food supply which provides all of these thirty-five principles in the proper proportion will supply proper growth in the young and maintain health in the adult provided it contains nothing deleterious."

The consensus of opinion as I interpret it, is that for dental health the whole diet must be considered and not any of its parts to the neglect of the rest. Analysis of deficient diets, however, discloses that they lack, in regard to the health of the teeth, in their content of calcium and the supply of the vitamins A, C and D; and that they tend to provide an acid rather than a basic ash.

To neither dentists nor pediatricists is it necessary to stress the need of calcium—and its associate phosphorus—for the building of teeth, which, like bone, consist essentially of compounds of calcium and phosphorus in a protein matrix. We are both aware of the need and we teach that an adequate supply must be taken and that nowhere can calcium be obtained to greater advantage than in milk, the universal food. We may not be aware, however, that growth can take place according to normal standards of weight and height with less than the optimal quantity of calcium, the bones and the teeth maintaining the normal form but being constantly deficient in their calcium content. This is an apparent exception to the law of minimum and it may be that it is an important cause of dental defects when the success of a diet is measured by ordinary standards.

We are all familiar almost to surfeit with Vitamin D and its effect on the growth of bone. It is likewise important in the growth and health of teeth.

Vitamin A, which is again coming into its own among advertisers following the recognition that irradiated substances containing Vitamin D cannot replace the time honored cod liver oil, has been shown to have a profound effect on the structure of the teeth and to be necessary for their proper constitution.

From the dental research worker investigating Vitamin C has come new light upon the importance of this vitamin so long the pet possession of the pediatricist in the cure and prevention of scurvy. It is now known that scurvy as commonly seen is a late manifestation of Vitamin C deficiency; that long before symptoms of scurvy become apparent, deprivation of Vitamin C makes itself manifest in injury to or lack of development of the supporting tissues of the teeth. Further it has been shown that for the proper growth of the teeth a larger intake of Vitamin C is advisable than has been thought necessary to prevent scurvy. Inasmuch as teeth start growing long before birth, Vitamin C is necessary very early, even during pregnancy.

I have adduced these few details from nutritional experience not because they are unknown to any of you but because they are so

well known. I hope that they may suggest to you first: that there is a great common ground of interest shared by the dentist and the pediatricist which should make them both eager to co-operate in the attempt to bring about a condition of dental health and second: that the pediatricist needs only to modify a little his point of view in regard to his nutrition work, to include the teeth as a part of it, using the means he now employs, in order to bring to the effort for dental health the

precious aid which the dentist is in all sincerity seeking.

I feel that the pediatricist yields to no other practitioner of the art of healing in unselfish effort to promote health, to help toward that goal of a good physician—the ultimate disappearance of the human ills by which he gains his livelihood. So, speaking for the pediatricist, with all confidence I pledge to his confrere, the practitioner of dentistry a loyal co-operation in the cause of dental health.

THE RELATION OF DISEASES OF THE MOUTH TO PEDIATRICS

By LEROY M. S. MINER, D.M.D., M.D., BOSTON, MASS.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

REGARDLESS of our approach, whether dental or medical, to the problems of the oral cavity and despite variations of opinion as to method and detail of attacking these problems, we can all probably agree as a starting point that the mouth is an integral part of the body and that mouth tissues, like other body tissues, are influenced by the same fundamental factors of health and disease.

In other words, efforts to promote health in the body will create favorable environmental influences for health in the mouth and subnormal physical states are likely to effect unfavorably the tissues of the mouth.

For some years I have insisted that the tissues of the mouth are sensitive to physical changes in the body and, thus to a degree, may be regarded as a barometer of health. Since tooth structure does not replace or repair itself when a part of it is lost from any cause, the apparent inactivity of cellular life in teeth has favored for many years the development and retention of the concept that teeth are essentially inanimate structures having no important relation to the other tissues of the body.

Experiments in the last few years, however, have demonstrated an active efferent and afferent circulation in tooth structure. Notable was the work of Weisberger who, in 1929, placed foreign protein, in the form of horse serum, in the dentin of guinea pigs' teeth and demonstrated by its effect on the smooth muscle of the uterus that it had passed into the circulation. Important also was the work of Howe, who fed ferrous acetate to laboratory animals and recovered iron in the teeth within thirty minutes. These and other researches in various fields of medicine and dentistry have largely dissipated the old idea that teeth are inanimate structures,

and they have also precipitated a broad biological approach toward dental problems. In the acceptance of a biological point of view, not only the pediatrician but all others engaged in any branch of the healing art must share with the dentist the responsibility for reducing the appalling prevalence of dental disease through the development of true preventive measures. The dentist, like his confreres in medicine has always been chiefly engaged in the treatment of disease. The repair of damage to teeth and their supporting structures has been his principal function. More recently, however, prevention of disease, or to use a better term, maintenance of health, in the mouth, has received vigorous attention, not only from the clinical but from the research aspect as well. This phase of the subject may well be emphasized, for in the prevention of disease in the mouth, the pediatrician has an important function to perform, and also a great opportunity.

Dental caries, the most prevalent disease afflicting human beings and the fore-runner of other disturbances, is distinctly a disease of childhood. Such evidence as is available indicates that the curve rises from the age of two, reaching its peak between ten and twelve years of age, then falls gradually with the exception of an occasional increase about the seventeenth year.

Various local measures, including rigorous hygiene, aimed to prevent or control dental disease, have not been successful enough to warrant the expectation that the solution of this problem rests with this type of activity. Oral hygiene undoubtedly has served a useful purpose because it has focused attention on the great needs for preventing tooth decay, and also because it has stimulated more concentrated study of causes,

which is vastly more important. Yet it has not materially reduced the incidence of the disease, and accumulated evidence indicates that the attack must be more fundamental.

Various researches devoted to dental disease have carried us to the point where it seems evident, first, that the development in teeth of cell health or cell resistance to disease is primarily a problem of nutrition and, second, that the building up of cell health cannot be started too early. From the dental point of view alone, the efforts being made now in pre-natal clinics, through nutritional and hygienic measures, to maintain for the prospective mother not only good health for herself during pregnancy but to supply to the offspring those elements essential to cell growth and the development of healthy tissues, both soft and hard, offer bright prospects for a material reduction in the tremendous incidence of dental disease.

It is important to remember that the first cells of the deciduous teeth are laid down about the ninth week of fetal life, that at about the seventeenth week the germs of the first permanent molars are formed and, finally, that the teeth are calcifying actively during the first two years after birth. In this period the dentist does not come in contact with the child at all. To the obstetrician and pediatrician we must turn for cooperation in our efforts to insure good foundations for the normal growth and development of the teeth and jaws.

Prevention of disease in the mouth is so closely related to normal growth and development of the child's body tissues that the whole matter, in the early stages at least, becomes more a pediatric than a dental problem per se. New knowledge constantly being developed in the field of mineral metabolism, especially the rôle played by the vitamins in this fundamental process, offer such hopeful prospects from a dental point of view that liberal support should be given this work.

Until this knowledge is developed to a point where prevention can become a practical matter, however, we will continue to face the insistent problem of dental disease, which must receive due attention.

There are two ways in which the pediatrician may be concerned with the control of disease in the mouth: First, through the effect produced in the tissues of the mouth by changes from normal in the body of the child, and, second, through the results produced in various parts of the body of the child by disease present in the mouth.

Unquestionably many physical factors exert an influence upon dental tissues, thereby predisposing them to disease. The classic experiments of Erdheim, who made a sub-total extirpation of the parathyroids in rats with the interesting sequel of the eruption of teeth devoid of enamel, suggest that defective calcification of teeth may

be the result of varying degrees of hormone dysfunction. The quality of tooth structure has only recently been given consideration. This matter was studied by Mrs. Mellanby, who found that 856 deciduous teeth out of 1036 examined had structural defects, and in 266 permanent teeth, 92 per cent were defectively calcified. Children whose six-year molars are devoid of enamel on the coronal surfaces and whose incisors and cuspids show the characteristic pits devoid of enamel, are not uncommonly seen. In many instances these children are found to have had a serious interference with nutrition during the first two years of life.

The effect of deficient diets on gum tissue in children is another demonstration of the intimate relation of body health to health in the mouth. Various degrees of gum inflammations from infantile scorbutus are still occasionally seen. Dentition is a normal physiological process, but when that process is disturbed physical causes should be looked for. This is distinctly the function of the pediatrician.

Physical disabilities, on the other hand, arising from disease in the mouth, are more spectacular and usually more readily recognized. Decayed temporary teeth have not been regarded as being of much importance. Yet it is a fairly simple matter to demonstrate various abnormal physical reactions attributable to such a condition. The irritation from decayed teeth on the nervous system of the child is common. Fretfulness and irritability are natural developments. The elimination of chorea, which sometimes yields to the removal of peripheral irritation in teeth, is a most satisfactory clinical experience. Furthermore, if a tooth is decayed, it is painful to chew upon and the child will either bolt its food or revert to a slop diet. In either event, disturbances of the gastro-intestinal tract, mal-assimilation and mal-nutrition are likely to follow in turn. This lack of masticatory function also favors lack of proper development of the jaws and nasal spaces, with the result of crowded permanent teeth, narrow arches, mouth breathing, diseased tonsils, enlarged adenoids, and subnormal respiratory function. Later, with infection developing at the root-ends, we find increased susceptibility to general infections. Some of the acute pyelitis cases in children are undoubtedly the result of dental infection. The relation of apical abscess to some of the heart infections also challenges attention.

With what we already know and with so much that needs illumination, no one can deny that complete cooperation between dentist and pediatrician is essential if we are to make any notable progress in the great task of controlling and preventing dental disease.

What may be done through this teamwork is demonstrated by the work of Boyd and Drain, a

pediatrician and a dentist. In one of their articles the following summary is quite worthy of attention:

"The intake of a diet rich in mineral salts and vitamins was found to result in arrest of dental caries in a group of twenty-eight well controlled diabetic children, 82% of whom had shown definitely progressive caries prior to the establishment of the dietary control. This indicates the dependence of dental caries on recent dietary inadequacies such as might be associated with the usual food intake of the average child."*

The relationship of diseases of the mouth to pediatrics is not only a research and clinical problem, it is an important educational one as

well, requiring a coordination of medical and dental education before much of a constructive character can be achieved. Important modifications of the curricula of both medical and dental schools must be made to accomplish it. Already it appears that the evolution has begun. An attitude of isolation on the part of the dental profession will delay accomplishment. Complete inclusion of dentistry in medicine cannot be expected at this time nor in the immediate future, but better coordination can be made, which means more medicine for the dentist and greater knowledge of mouth problems by the physician. With both groups meeting together for purposes of mutual help, many of our present difficulties will disappear.

THE RELATION OF DISEASES OF THE MOUTH AND TEETH TO PEDIATRICS AND INTERNAL MEDICINE

By WILLIAM DWIGHT TRACY, D.D.S., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

A STUDY of this interesting subject may lead an essayist into devious ways and into many ramifications of cause and effect, but it will be the object of this brief paper to touch upon those obvious departures from the normal which definitely influence the health index of the infant and the growing child. Regarding the oral cavity as the chief portal of entry to the human organism and realizing that all nutrient material passes through this portal into the digestive system it is evident that a healthy mouth containing a normal and efficient complement of teeth is a primary factor in the well being of the child.

One of the most critical defects encountered in infancy is congenital cleft palate usually accompanied by harelip. This distressing malady frequently results in difficulty in nursing and infants so handicapped are often undernourished and become a problem for the pediatrician. The surgical reduction of this deformity has been developed to a fine art, and much credit belongs to members of the dental profession for their contributions to this evolution in surgical procedure. Early operation upon infants is now standard procedure and the restoration to normality in form and function and freedom from serious outward blemish places this operation in the class of great human benefaction.

Diseases of the mucous lining of the oral cavity, such as aphthous sores and thrush, and the preliminary symptoms of measles, are disturbing influences which the pediatrician is much more likely to be called upon to treat than is the dentist. Vincents Infection, distressing and disagreeable when it does occur, is rarely reported

among infants and usually responds to standard treatment with agents rich in oxygen. If infection of this type is not discovered early in its course and if the fauces become involved treatment and control of the trouble are difficult and complications of a serious nature may occur.

Teething—Teething of infants is a physiological process and in the case of a normal healthy child is usually accomplished without complication. Instances of difficult dentition accompanied by irritation, inflammation, pressure and swelling are not infrequent and are sometimes overlooked in the search for the cause of the secondary symptoms that are evident in these cases. On the part of some specialists there seems to be a tendency to ascribe any one of many symptoms exhibited by the infant from six months to two years of age to teething while others pass lightly over this possibility on the basis that it is a normal physiological function and should, therefore, be causing no disturbance.

As a matter of fact the disturbances incidental to difficult dentition of the deciduous teeth in certain cases are very real, and can assume a serious aspect. Reflex disturbance of the vegetative nervous system may throw the digestive functions entirely out of balance interfering with nutrition and causing a general upset in the orderly process of the child's natural routine. The present day well trained specialist in children's diseases recognizes these conditions and understands how to meet them and when called in consultation the experienced dentist can readily locate the trouble and administer relief.

After dentition of the deciduous set is com-

plete and all twenty of the deciduous teeth are in place the child should normally enjoy dental comfort and efficiency without material change up to the sixth year. This enjoyment, however, is based on the premise that the teeth have erupted in proper position and that normal occlusion has been established. It is also based upon the premise that the teeth themselves have normal resistance to those influences which induce dental caries.

If on the other hand the growth of the jaws has been inadequate and the temporary teeth are in malposition these defects interfere with proper mastication of the food and may be a real handicap to the little patient. It is true also that teeth which are in malposition and which are difficult to keep clean are predisposed to caries.

It is the consensus of opinion among practitioners of dentistry that every little child should be examined at two and a half or three years of age in order that incipient caries may be caught in its early stage and cared for before serious damage has taken place. It also provides opportunity to note congenital departures from the normal or unfavorable changes brought about by habits of childhood such as thumb or finger sucking or similar adverse influences. In an effort to prevent serious damage to the teeth dentists in private practice urge patients to arrange for examination and cleaning at least twice a year. In many cases more frequent calls on the dentist are necessary.

It seems pertinent here to point out the fact that neglect of the deciduous teeth may have a far-reaching influence upon the health, strength and development of the growing child. Normal digestion and metabolism are the birthright of the child, but when the function of mastication and incidentally the proper insalivation of food become impossible for the child because of deep-seated and painful cavities of decay normality ceases. Chewing becomes a lost art with the patient; food is bolted, the appetite wanes, the weight index goes astray and growth is restrained.

When a child presents showing a listless bearing, a pasty complexion, dull eyes, lustreless hair, dry lips and a coated tongue, these symptoms are not always due to dental defects of course. It is safe to say, however, that in seventy-five per cent of such cases an examination of the oral cavity will disclose a deplorable state of affairs; teeth broken down through the ravages of caries and in partial or complete dysfunction, gums turgid, spongy and inflamed, interdental spaces packed with fermenting food pabulum and debris, pus oozing from one or more chronic abscesses and mucous membranes red and congested. Orange juice, cod liver oil and sunshine may be of some benefit to such a patient, but until the lesions in the oral cavity are recognized

and treated with a view of eliminating infection little can be hoped for as a result of general treatment.

When the conditions involving the oral tissues and the teeth are cleared up and such teeth as can be salvaged are properly repaired the rebound toward health in the majority of these cases is most gratifying. Proper hygiene and dietetic measures applied to such a child at this juncture will be an important factor in restoring it to normal. We are, therefore, constrained to admit that the deciduous teeth are an important factor in the health of the growing child and that every effort should be made to keep them intact and capable of performing their normal function until exfoliation takes place.

After six years and up to the twelfth year of age the deciduous teeth are being shed and their permanent successors are coming into place. There are usually no dental complications affecting the general health of the patient during this period, but in case orthodontic treatment is necessary when a child is below par, the advice and council of the family physician is invaluable.

It is perhaps needless to say that constant watchfulness and periodic examination are essential to discover dental caries in its incipient stages and thus safeguard the integrity of the dental pulp. The death of a pulp in the mouth of an adolescent patient which used to be considered as one of the unavoidable events in dental practice is now regarded as nothing short of a tragedy and while much advance has been made in the treatment of these cases the pulpless tooth is still a problem in which both dentistry and medicine are necessarily much interested.

The third molars are more or less erratic in the time of their eruption, but are usually found in position between eighteen and twenty years of age. Delayed eruption of these teeth is common and the complications that arise from impaction may be serious including extreme discomfort, swelling and trismus, not infrequently accompanied by infection. Incidents of this type may result in systemic disturbance necessitating hospitalization and treatment at the hands of the physician.

Assuming now that all teeth of the permanent denture are in place we will review briefly some of the conditions wherein there is an interrelation between dental and oral lesions and the systemic condition.

Pyorrhœa—One of the most trying maladies with which the dentist has to cope is periodontoclasia or *pyorrhœa*, and while local factors in the cause of this disease usually predominate there are frequently systemic conditions which may be present as causative and perpetuating factors. Faulty habits in general hygiene, defective elimination, unbalanced diet, inadequate intake of fluids, are all factors which have a definite bear-

ing on the incidence of this disease and upon its control and cure. The advice and council of the internist is of great assistance in the management of these cases. It is well known that diabetic patients and patients having Brights Disease are predisposed to periodontoclasia and as a class respond less favorably to local treatment than do those in whom such diseases are not a factor. And here again collaboration with the physician is essential.

Focal Infection—The study of focal infection of dental origin from which secondary symptoms may arise, perhaps brings physicians and dentists more frequently and more closely together than any of our other numerous and perplexing problems. This subject, however, is so profound and so broad that anything more than a brief comment upon it is quite outside the bounds of a brief paper of this sort.

In a search for the causes of loss of energy, debility, and malaise the oral cavity and teeth must not be overlooked. Foci of infection at the apices of pulpless teeth are not the only lesions to be observed, as a low grade infection may exist as a chronic gingivitis from which bacteria may readily enter the blood stream through the inflamed and engorged tissues which are rich in their vascular supply. The disagreeable pockets which are found about and between teeth which are affected with periodontoclasia and which are frequently bathed in pus must receive due consideration and treatment. When all possibilities of primary infection in the oral cavity including a study of the tonsils have been canvassed and the sinuses have been eliminated from the diagnosis the case then becomes a problem for the internist.

In cases of difficult and obscure diagnosis it is interesting to note that many medical practitioners nowadays desire to eliminate all possibilities of infection above the "collar line," as one prominent diagnostician has said, before proceeding further. Thus the dentist and medical practitioner have been drawn more closely together in a common interest. While there seems to be no literature on the subject an internist reported to the writer that he had gained the impression that there was a direct relation between chronic pyorrhœa and stomach ulcers, and that he felt this was a subject worthy of special research in which the physician and dentist could advantageously cooperate.

Caries—Dental caries is undoubtedly the most prevalent and widespread of all human diseases. It is without question one of the most potent factors in the cause of reduced vitality, lowered resistance and systemic disease. Physical inefficiency and ill health are costly to the individual, to the community and to the nation, and while many of the keenest minds in dentistry have been devoted to a study of the causes and pre-

vention of caries for a great many years it is still, in the last analysis, an enigma.

Many students of the subject seem to feel that the food habits that are incidental to our super civilized methods of living are at the root of the trouble, but even when controlled groups are placed upon a so-called correct diet and kept under supervision for long periods of time the results are none too salutary. Among the many types of research which are constantly being carried on in dentistry in this and other countries the problem of caries is probably receiving more attention than all other activities together and among those who are studying caries the dietetic approach seems to be the dominant idea.

While the problem is one in which all members of the healing art are interested your essayist is impressed with the fact that it is quite as much the obligation of the medical fraternity as it is of dentistry to aid in solving the enigma. In other words, medicine must share the responsibility of carrying on intensive and continuous research along any line that gives promise of shedding new light on a major problem still shrouded in mystery. We are well aware that many workers who hold no dental degree and some who have neither medical nor dental degrees have made valuable contributions to research in dental problems, but the time has come when medicine and dentistry should muster jointly all their research possibilities in a common effort to discover the actual basic cause of dental caries and to seek its prevention.

Since writing the foregoing an important paper on the Etiology of Dental Caries by Alfred F. Hess and Harold Abramson has appeared in the Dental Cosmos from which it seems appropriate to quote as follows: "Dental caries is the most important nutritional disorder in this country today; it is a universal problem. It is futile to hope that it can be solved by the dental profession alone. Like rickets, it will probably require the combined investigation of biochemistry, animal experimentation and clinical medicine. In order not to fall into the same errors which have occurred from time to time in connection with investigation of vitamin deficiency, it should be constantly borne in mind that the final criterion is the clinic and not the laboratory and that, if experimental results do not coincide with dental experience, they must be judged erroneous."

We know and appreciate the value of oral hygiene, of reparative and restorative dental operations, but while a small percentage of those needing such treatment are receiving it, we are staggered by the incoming flood of dental defects in the mouths of the rising generation with which we know we cannot begin to cope.

One of the most encouraging signs pointing toward medical interest in dental problems is the work now going on at Yale University in which

medical and dental men are working together in joint research. If, from all the work now being done and still to be carried on, science, aided by

medicine and by dentistry, should find a way to prevent dental caries it will be one of the greatest benefactions that could come to the human race.

THE BACTERIOLOGY OF DENTAL INFECTIONS AND ITS RELATION TO SYSTEMIC DISEASE

By RUSSELL L. CECIL, M.D., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

DURING the last twenty years much has been written about dental infection and considerable research has been carried out in this field, yet comparatively little is known about the real pathogenesis of these infections. We need to ask only one or two pertinent questions to realize how ignorant we still are along these lines. What causes dental caries? Is it primarily an infection, or do bacteria simply invade the careous areas and lead a saprophytic life there? Why do people get pyorrhea? Again, are we dealing primarily with an infectious process, or is some fundamental disturbance in the metabolism responsible for the condition? Tonight I wish to sketch briefly our present knowledge of dental infection and give you a résumé of its bearing on systemic disease. Most of this information is familiar to you, but we go to medical meetings as we go to church or the opera, to hear what we already know.

Focal infection is now a well-established principle in medical practice. The careful physician examines the teeth as thoroughly as he does the lungs and heart, and one of the most difficult problems that confronts the medical man today is when he should, and when he should not, have a pulpless tooth removed. But before discussing this point, let us review briefly the common bacteriology of dental infections.

Technic of Taking Cultures—Haden's method of culturing an extracted tooth is the one the writer has usually followed. The field of operation is prepared by first rubbing with gauze the tooth to be extracted. The tooth and gums are then painted with iodine, the iodine removed with alcohol, and the area of operation walled off with sterile gauze. The tooth is then extracted with sterile forceps. After extraction the apex of the tooth is cut off with a sterile instrument and dropped directly into a tube of culture medium. Haden prefers to drop the apex of the tooth into sterile salt solution which contains a small amount of sand. The tube is then well shaken to macerate the tissue on the tip of the tooth, and cultures are made from this material. In taking cultures from pyorrhea pockets, the teeth and gums should be sterilized in the same manner. The field of operation is protected with

sterile gauze, a platinum loop is inserted well into the pus pocket and cultures made from the material removed. It is needless to say that all cultures taken from the abscesses of teeth or from pyorrhea pockets should be plated out on blood agar plates in order to separate the various species of bacteria present.

Bacteriology of Caries—Dental caries still remains one of the great mysteries of medicine. It has been attributed to calcium deficiency, vitamin deficiency, acid mouth, faulty mouth hygiene, bacterial infection, etc. Caries will probably be found to result from a combination of etiological factors. The infectious theory of dental caries was first advanced by W. D. Miller, who thought that caries resulted from the activity of certain bacteria in the oral cavity. These bacteria were supposed to produce acids which injured the enamel of the tooth, and thus gained access to the dentine which, by reason of its organic nature, they were able to attack directly. In 1922, James, Macintosh and Barlow isolated an organism which they called *bacillus acidophilus odontolyticus*. When sound teeth were placed in broth cultures of this organism, white opaque spots appeared on the surface of the teeth, indicative of decalcification of the enamel. In 1924, Clarke described a streptococcus which he found almost constantly present in careous dentine. When the careous material was spread on blood agar plates, small gray colonies resembling those of streptococci were found in considerable numbers. The organism was an aerobe and microscopically grew in typical streptococcal chains. Clarke called this organism *streptococcus mutans*. The exact relationship of these bacteria to dental caries still remains to be determined, but there is no reason to doubt that bacteria do play an important part in the etiology of caries.

Bacteriology of Pyorrhea Alveolaris—Pyorrhea alveolaris is really an infection of the dental periosteum and the alveolar process, characterized by purulent discharge from the alveolus and, if not checked, by loosening and eventual loss of the teeth. The bacterial flora of pyorrhea is nearly always mixed. The commonest pathogen is *streptococcus viridans*, though occasion-

ally streptococcus hemolyticus is encountered. The plates in most cases will also show a few colonies of staphylococcus albus. By the use of stained smears and anaerobic cultures, it can be shown that fusospirochetes are nearly always present and often in large numbers. It is the presence of these fusospirochetes which give the unpleasant odor to the pyorrheic mouth.

Bacteriology of Alveolar Abscesses—Acute alveolar abscess, or "gum boil," as it is called by the laity, usually but not always arises from a pulpless tooth. The bacteria invade the pulp, escape through the apex of the tooth to the periodontal membrane, and excite acute inflammation. Sometimes the alveolar abscess arises from extension of a pyorrhea pocket. Those due to apical infection usually yield a pure culture of streptococcus viridans or hemolyticus. Those that result from periodontal infections are often caused by staphylococcus aureus.

Bacteriology of Apical Abscesses—Chronic apical abscesses have received considerable bacteriological study. Perhaps the most recent and most careful studies are those of Russell Haden who, in 1926, reported on cultures from the periapical tissues of 1,500 teeth. Streptococci, either alone or mixed with other organisms, were present in 92.5 per cent of the positive cultures; gram positive bacilli alone were found 58 times; staphylococci alone 19 times. According to Haden, the nonhemolytic streptococcus was by far the most commonly found organism. Hemolytic streptococci were comparatively rare. These findings differed somewhat from those of Henry, Sniffen and Doyle who, in an extensive study of chronic apical abscesses also found streptococci to be by far the predominant organism, but who found hemolytic streptococci in a considerably higher percentage than that of Haden. All observers are agreed, however, that streptococcus viridans is by far the commonest bacterial agent in chronic apical abscesses. Some of the streptococcal strains isolated from apical abscesses are intermediary in character, that is, they have some capacity for producing hemolysis when first isolated, but after prolonged cultivation on culture medium, they lose their hemolytic quality and become typical viridans strains. Apical abscesses frequently contain fusospirochetes as shown by the frequency with which a putrid sinusitis develops when an apical abscess extends into one of the antra.

Bacteriology of Devitalized Teeth—Rosenow, Haden, Henry and Doyle, and many others, have recovered streptococci from a high percentage of pulpless teeth, irrespective of whether x-rays were positive or negative for periapical infection. For this reason Rosenow believes that all devitalized teeth should be extracted. Furthermore, he believes that devitalization of teeth and filling of root canals should be discon-

tinued, and that for the present at least it is wiser to remove teeth that have become infected than to retain them at the risk of their becoming an insidious infection later.

Bacteriology of Vincent's Angina—This is a gingivitis beginning in the free margins of the gums and characterized by acute necrotic inflammation which spreads rapidly. The gums are tender and painful, the breath is foul and there is some systemic intoxication as evidenced by fever and general malaise. Fusospirochetes are found in large numbers in the ulcerated margins of the gums and the condition is readily diagnosed by means of a smear from the ulcerating surfaces. These fusospirochetes are originally anaerobic and do not show on aerobic cultures. Most of them were first cultivated in pure form by Hideyo Noguchi.

Experimental Focal Infection—Focal infections about the teeth have been produced experimentally by Rosenow, Haden and others. Rosenow and Meisser devitalized and infected the teeth of dogs with the staphylococcus from a case of nephritis. One dog developed pyelitis and cystitis with marked calcareous deposits in the pelvis of the kidney. The same authors recovered streptococci from the infected teeth of patients with nephrolithiasis. The teeth of healthy dogs were then devitalized and the pulp chambers of these teeth infected with heavy suspensions of the streptococci. The infected teeth became discolored, but remained firmly in place in the alveolar sockets. These infections caused rarefaction and absorption of bone in the periapical region without swelling or tenderness. Renal calculi or lesions in the medulla of the kidney developed in a high percentage of the dogs whose teeth were infected in this manner. Later Meisser produced experimental ulcer of the stomach by the same procedure, that is by injecting into the root canals of dogs streptococci obtained from the infected teeth of patients with gastric ulcer. Strangely enough this experiment failed when an attempt was made to produce experimental arthritis by this method. Rosenow thought that this failure was due to the fact that streptococci from patients with chronic arthritis were less virulent than the other strains. I think it more probable, however, that his failure was due to the high natural immunity which dogs possess against infections of the joints. In most of the experimental work, the streptococci recovered from infected teeth have not been injected into the tooth sockets of animals, but directly into their veins. A large amount of experimental work has been done along this line. Henrici, Moody, Rosenow, Price, Meisser and Gardner, Haden and others have all made extensive studies of the lesions in rabbits which follow the injection of streptococci from infected teeth. This of course leads us to

Rosenow's well-known theory of elective localization following the intravenous injection of streptococci. His theory is that the streptococci which are present in infected tonsils, teeth and sinuses have a special affinity for certain organs. Some localize in the joints, some in the heart, some in the appendix, gall-bladder or kidney, some in the gastric mucosa, etc. Rosenow found that as a general rule streptococci which have been obtained from various foci of infection tend to localize and produce lesions in animals corresponding to those in the patients or in the animals from which the micro-organisms were originally isolated. In other words a streptococcus from the teeth or tonsil of an arthritic tends to produce arthritis when injected into a rabbit. The streptococcus from a focus in a patient with pyelitis tends to produce pyelitis in the experimental animal, etc. Rosenow's doctrine of elective localization has not received universal acceptance, though I believe there is more evidence in its favor than there is against it. The carefully conducted experiments of Henrici, Haden and others have corroborated in great part Rosenow's findings.

Dental Infection and Systemic Disease.—The theory of selective affinity of bacteria naturally leads us to a discussion of systemic disease in its relation to dental infection. The relation of infection to systemic disease began to receive recognition from medical men as early as 1900, when William Hunter of London wrote several articles on the subject. Shortly after this there appeared the studies of Billings, Camac, Kinnicut and others, all of whom reported cases of arthritis or some other systemic disease which were etiologically connected with foci of infection about the teeth. It was largely through the influence of Billings that Rosenow took up his bacteriological studies of focal infection and made his important contributions in this field.

The distant effects of dental infection are usually caused by the streptococcus, but before referring to streptococcal infections, a word should be said about the relation of fusospirochetes to pulmonary infections. It is a well-recognized fact that bronchiectasis and lung abscess are much commoner in hospital than in private patients. It is particularly common in the Bellevue type of patient, that is, in the type of patient whose mouth hygiene is proverbially bad. The studies of Smith indicate pretty clearly that bronchiectasis and putrid abscess of the lung are caused at least in part by the fusospirochetes. The fusospirochetes are present to some extent about all healthy teeth, but they are particularly numerous in patients with pyorrhea and gingivitis. It seems reasonable to suppose that the prevalence of lung abscess and bronchiectatic cavities in patients with pyorrhea is related to the presence of these micro-organisms, and the lesson to be learned is that proper mouth

hygiene will considerably diminish one's susceptibility to bronchiectasis and lung abscess.

When we come to a consideration of streptococcal infections about the teeth and their relation to systemic disease, we think first and foremost of infectious arthritis and justly so, for so many cases of arthritis in middle and later life are due to dental infection. In our studies on arthritis at Bellevue Hospital, we have frequently succeeded in isolating streptococci from both the blood and joint fluid in patients with infectious arthritis. In some of these patients a streptococcus has also been recovered from the apex of an infected tooth. It was very significant that in these cases cultural and agglutination tests established the biological identity of the three streptococci.

Associated with infectious arthritis there is often involvement of the muscles, tendons and bursae by the same organism. Likewise these tissues may be infected without involvement of the joint. Brachial neuritis, sciatica and facial neuralgia not infrequently are due to dental infection. I have found in private practice that most cases of neuritis are due to either trauma or focal infection. We must assume that an arthritis due to a focus of infection in the tonsils or teeth results from the direct localization of bacteria in the joints. Bacterial allergy probably plays an important part and influences the course of the disease, but the actual process in the joint is an infection analogous in every way to gonococcal infection in the joint which results from a gonococcal focus of infection in the prostate gland.

Next to arthritis one would naturally think of endocarditis of either the rheumatic or bacterial type. I have several cases of bacterial endocarditis in mind where the pre-existence of marked periodontal infection seemed to point to a close association between the two conditions.

Another interesting group of metastatic infections are those of the iris and uveal tract. De Schweinitz states that there is no better established etiological relationship than that between septic foci in dental areas and certain diseases of the eye, especially those of the uvea. Rosenow has reported cases of eye infection from dental pulpitis with reproduction of the lesion in animals. Haden has also reported a group of ocular disorders due to dental infection.

The most striking example of connection between focal infection and the kidney is that of glomerular nephritis which follows scarlet fever with the tonsils as a focus, but no doubt the root abscesses around teeth can also excite renal irritation, particularly in the pelvis.

The relation between focal infection about the teeth and gastric ulcer, appendicitis and infections of the gall-bladder is a little more difficult to establish, but Rosenow and others have brought forward considerable evidence in sup-

port of such a theory. Certainly streptococci can be recovered from most of these infections.

The relation of dental infection to mental disease has received extensive investigation, particularly at the hands of Cotton, who has made elaborate studies in this field and has written a monograph on the subject. Cotton believes that a great many of the so-called toxic psychoses are the result of focal infection, particularly in the teeth. In his work at the New Jersey State Hospital for the Insane, Cotton found that by removing infected tonsils and teeth he was able to bring about recovery in a great many psychotic patients who otherwise appeared incurable. Cotton believes that by far the most important focus of infection in the insane is the apical root abscess. He feels, however, that the infection often spreads from the teeth to the tonsils, stomach and intestinal tract, and that these secondary foci may persist after the teeth have been extracted and cause a continuation of symptoms. Cotton also believes in the therapeutic value of autogenous streptococcus vaccine. He has been criticized as being too optimistic in his ideas concerning the prevention and cure of mental disease by the removal of focal infections, but even granting that he is perhaps too sanguine, I doubt if anyone will question the statement that every mental case should have adequate attention given to his tonsils, teeth and sinuses. Henry, Sniffen and Doyle have recently reported their findings in the bacteriological study of root canal infection. They found streptococci with equal frequency in the extracted teeth of both psychotic and nonpsychotic patients, and in their investigations at the Bloomingdale Hospital, no specific relationship could be established between dental infection and any particular type of psychosis.

One of the most interesting phases of focal

infection is its relation to bacterial allergy. The studies of Swift and his co-workers at the Rockefeller Institute have shown that the experimental production of a streptococcal focus in a rabbit produces a state of bacterial allergy in the rabbit. In other words, the rabbit is more sensitive than normal to this germ. If the rabbit is then given intravenous injections of streptococcus vaccine, the allergic state can be transformed into an immune state in which the rabbit is entirely resistant to streptococcus infection. In other words, there appear to exist three different states of resistance to bacteria, both in animals and in man: First, the normal state of resistance in a healthy organism; second, the allergic or hypersensitive state; third, the immune state. Clawson has corroborated the work of Swift and has shown that in the animal artificially immunized, streptococcal agglutinins are present in the blood. From these studies we can begin to understand the method by which focal infections set up infections in other parts of the body, and we also have the basis for a rational vaccine therapy. In our arthritis clinic at Cornell, our first task in the treatment of rheumatoid arthritis is the discovery and removal of all foci of infection; second, the immunization of the patient against the germ, usually the streptococcus, with which he is infected. Most of our vaccine is now administered intravenously, as this seems the method of choice both in theory and practice. The treatment of systemic disease secondary to focal infection does not end, however, with the removal of the focus and the use of vaccine. The patient's general health must be built up in every way by rest, exercises, diet, vitamins, etc. With proper handling these patients respond quickly and usually make a complete recovery.

ORAL DIAGNOSIS AND DISEASE IN OTHER PARTS OF THE BODY. WHAT HAS ORAL DIAGNOSIS TO OFFER?

By EDWARD H. HATTON, M.D., CHICAGO, ILL.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

THE field of oral diagnosis is relatively, though not wholly new. Like every new enterprise, it has been received with lively enthusiasm by some, with a bored attitude of distrust and suspicion by a great number and with actual resentment by those settled in conservative methods of practice. There are others who are totally ignorant of it or, who, if dimly aware of its intrusion into the healing art, have no conception of its objects and the service that it proposes to render to patient, physician and dentist.

From the standpoint of the true oral diagnostician this situation is the challenge to his skill,

to his training and to his motives that governs his activities and supplies the guiding principles for the conduct of his practice. He must not be carried off his feet by undue enthusiasm which in no sense is a substitute for ability. He is obliged to overcome the handicap imposed by those who have entered this new field because it promises easy profit for a service but little understood or standardized and therefore easily exploited. This is important, for the activities of the latter have served in no small way to convert the attitude of watchful waiting into one of total distrust of the value of the services which can

be rendered by the oral diagnostician. He is under great pressure therefore, to produce results that justify his existence, to cooperate in every way with practitioners in the field of medicine in order to supply a service that saves the patient both in the prevention of pain and prolonged illness and in the reduction, if possible, of the cost of medical care. An excellent illustration of the extent to which this is possible has been supplied by Dorrance.¹

To no slight degree, success in this field is a factor of the degree of confidence and respect that both the patient and physician may have in the character, ability and judgment of the oral diagnostician. This is not a new situation and in this sense this statement is trite and commonplace. But it is so lamentably and, even frequently justly true that it deserves emphasis. Lamentably true in the instance that the majority of physicians prefer to select teeth for extraction rather than to rely on the judgment of the dental diagnostician, and justly true because many so-called oral diagnosticians do not deserve any degree of respect or confidence. Such a situation has arisen because dentistry as a profession traditionally does not have the high standing that is accorded to medicine and partly because but few of the medical schools have included such subjects in their courses as tooth and jaw anatomy, histology and pathology. Even the subject of focal infection has been handled for the most part superficially and in a way to hamper rather than facilitate its use as a diagnostic and therapeutic resource. A recent text on pathology states:—"The importance of the teeth as sites of focal infection has been overemphasized by many physicians. Latent dental infections (root granulomas) are seldom responsible for metastatic lesions. Hypertension is not due to focal infection, and the practice of extracting suspected teeth in this condition is to be condemned. Obscure anemias are usually not caused by focal infection."² I am not questioning the correctness of this statement, it is offered merely in justification of my belief that this subject is not adequately covered in the medical courses.

On the other hand this state exists because dentistry as a profession does not have the high standing that is accorded to medicine and because, to a certain degree, the dental schools have not been in a position or willing to teach their students the fundamental principles of disease and have substituted for that an entirely superficial and totally inadequate picture of the nature and genesis of sickness. The methods in vogue even in some of our most ambitious dental institutions in selecting students have placed *undue emphasis* on the *length of their preparation rather than on native ability*: Social and economic prejudices have operated to further reduce the number

of desirable applicants for dental training. The budgets of dental schools have not been large enough to provide faculties competent to function adequately both in technical training and instruction in the nature of disease so that the former has been emphasized at the expense of the latter. The physician is cognizant of this state of affairs in a general way and has but little respect for the dental practitioner in this sense. The dentist unconsciously becomes the victim of his "little knowledge," forgetting in his comparative ignorance that it is "a dangerous thing." And in a way he can hardly be blamed for his confidence in his little knowledge and the necessity for making the best possible use of it, at least after one experience with a physician who has stubbornly interpreted a mental foramen shadow as an alveolar abscess in reading a Roentgenogram, or with one who is totally ignorant of recent discoveries in the field of nutrition and unable to formulate a therapeutic diet. Fortunately there are outstanding exceptions to these general statements that are most promising for the future graduates in both medicine and dentistry. For the present we shall have to do the best we can to remedy this bad situation, a solution that has been found in a number of outstanding instances where profitable relationships between the two groups have been established over long periods of time. Certainly the situation is much better in large urban centers, such as the one from which the audience has been drawn, although I suspect that even in this group those who could profit the most from meetings such as this are conspicuous by their absence.

May I address some remarks to the physicians in the audience, to justify the belief of the oral diagnostician that it is highly important to preserve the natural structures of the mouth as far as is consistent with the health of the patient. Or to put this in different language, preservation of the mouth structures in active function is highly consistent with the maintenance of general health and, in many instances, actually is responsible for the prevention or cure of conditions that we are prone to believe due to diseased teeth. I shall comment on only one phase of this problem which has to do with work of a very competent physiologist of the younger group, A. C. Ivy. He has traced a series of digestive disturbances to incomplete and improper mastication such as, cardiospasm, chronic dilatation of the esophagus, delayed emptying of the stomach, stomach indigestion, hyperacidity, gastric ulcer, pylorospasm, etc. He has produced typical gastric ulcer in experimental animals, such as rabbits, by appropriate methods based on this hypothesis. This seems to me to be important as we are prone to think that gastric ulcer is to be considered as one of the results of focal infection of the teeth and that it is forerunner of gastric cancer. The *idiosyncrasy* of many indi-

¹ Dorrance, Oral Surgery Clinics, Dental Cosmos. 70:405 (1928).
² Bell Text book of Pathology, p. 112.

viduals to certain articles of food, such as cabbage, onions, cucumbers, etc., in his opinion is not a true idiosyncrasy, but in a large number of instances is due to incomplete mastication, resulting in long retention of large fragments of these foods in the stomach. I speak of this merely to justify this point of view of the oral diagnostician and not to discuss a subject which in itself might serve for a full evening's program. I wish to urge physicians who seek the service of dental consultants to encourage this type of cooperation and to act as energetically in conserving mouth structures where indicated as in eliminating teeth that are inimical to health. It is my thought that such service is much more constructive than that offered by the radical type of dental consultant who is prone to condemn every structure not entirely above suspicion.

It is my impression that the able dental consultant has great faith in the reliability of the Roentgenographic examination although he is keenly aware of its limitations and of the difficulties encountered in its interpretation. He knows that it is only one of a number of diagnostic resources and even under the best of conditions hesitates to press an opinion based solely on the information supplied by it. He is and must be a good judge of what constitutes adequate Roentgenographic examination and of the quality of the films that be submitted for study. It is to be regretted that the Roentgenogram has fallen into a measure of disrepute, because I am quite confident that this has happened largely because a very considerable proportion of the films made are of such a character as to practically nullify interpretation and because routine examinations in many cases are wholly inadequate and incomplete. This is especially true of the Roentgenographic examination of pulpless teeth. I know of a number of papers that deal with the deficiencies of this diagnostic procedure, particularly comparison between Roentgenographic and bacteriological studies of pulpless teeth in which the former makes a rather bad showing. However, on the other hand, equally competent investigation has demonstrated, I believe, that if the Roentgenographic examination is sufficiently thoroughly done, so as to expose the apex at a number of different angles and so as to produce well differentiated films, the discrepancies between the pathologic and Roentgenographic findings can be reduced to a figure lower than that for any other type of laboratory examination. But I do want to emphasize my belief that although Roentgenographic interpretation is relatively simple, it should be made by one who is thoroughly familiar with the anatomic structures of the parts examined, with the pathologic processes that induce changes in these structures and with the limitations and technique concerned with its use. I must repeat that I believe that Roent-

genographic evidence by itself is not a sufficient foundation for an oral diagnosis.

The process of infection which eventually involves the apical space and hence produces changes that can be recorded in the Roentgenogram is ordinarily sufficiently rapid to be seen in the films soon after its beginning. But there is a group of cases that is becoming more common and in which this is not true, because the apical changes are either late or do not appear at the time the case receives clinical consideration. It is in this group that Roentgenographic examination is deceptive. For the most part these are limited to pulp infections under such large restorations as amalgam fillings, inlays and crowns. For some cause, little understood, such infections are often limited to and encapsulated practically within the coronal pulp, particularly of bicuspid and molar teeth and in such forms must be considered as potential foci of infection. Because the Roentgenogram is negative and because of the absence of the vagaries of the clinical symptoms an accurate diagnosis is difficult. All of the signs and symptoms may be associated with neighboring pulpless teeth which are always under suspicion so that one may be led by this kind of reasoning into a serious diagnostic error. A single illustration may demonstrate these points, at least in part. A young woman complained of severe, neuralgia-like pain in the upper bicuspid region and parallel to the distribution of the second branch of the fifth cranial nerve. In this region she had a pulpless bicuspid which was at once suspected as the cause of her trouble, but all therapeutic measures employed to relieve it short of extraction were without effect. After two sleepless nights without any measure of relief despite the use of sedatives, some consideration was given to more remote teeth that might be diseased. A lower bicuspid carrying a large inlay was carefully examined and because of slight variations from normal reactions, it was thought wise to investigate it farther. Removal of the inlay and opening the pulp chamber disclosed pus under pressure, drainage of which promptly relieved all symptoms. It is in the solution of problems such as this that I think that the dental consultant can be of great value.

On the whole, in the interpretation of the information supplied by the laboratory, the average practitioner of internal medicine is a keener judge than the dental consultant. But there are certain phases of this interpretation that present distinct difficulties in the solution of which the former is decidedly handicapped. This seems to be particularly true when it has to do with the pathological examination of biopsy material. In two conditions the clinical findings and the laboratory reports deserve special consideration. Epithelial changes and proliferation in the specimens removed from the mouth are often of a note-

worthy and puzzling character, not only of the mucous membrane covering, but also of the epithelium found in the space between the tooth and the bone, in apical granulomas and in root cysts. They are of such a character that the pathologist without much experience in the examination of such material is prone to make a diagnosis of malignancy. I have come to distrust such opinions as the result of many experiences of this kind. In the same vein, I suspect, many of you are familiar with the opinion of at least one prominent surgeon that all epithelial structures found in apical granulomas are to be diagnosed as suspicious of adamantinoma, a slowly malignant form of epithelial tumor; an opinion that would warrant such excessive surgical interference in treating them that the end results would be ghastly. The prognosis of the giant cell tumor of the gums, sometimes called giant cell sarcoma, is entirely different from the giant cell sarcoma of the long bones. In such cases the interpretation of the oral diagnostician is usually much sounder than that of the general pathologist or general surgeon. In one other respect in the interpretation of laboratory reports the oral diagnostician may be of some service to both patient and physician, and that has to do with the correlation of mouth findings and laboratory reports where the latter are positive for *B. fusiformis* and the spirillum of Vincent. Not all of these are to be accepted as bona fide cases of a specific stomatitis. It must be a matter of great moment to all individuals concerned that early in such diseases as the leukemias, agranulocytosis, etc., the mouth smears are quite typical of an uncomplicated ulcerous stomatitis. I have purposely omitted the subject of syphilis from this paper, although it may well have had a place. But the part played by it is pretty well known by physicians. It may be dismissed with the observation that, as a rule, physicians are more helpful to dentists than vice versa, in solving the problems that arise in connection with its diagnosis and the treatment of the lesions found in the mouth. There is a very interesting association of mouth conditions with many of the skin eruptions treated by dermatologists and well known to the latter group, as some of the best descriptions of these mouth lesions are from the pens of such men as Fordyce, Pusey and Wise. One puzzling property of the mouth lesions is their tendency to persist long after the return of the skin to normal. A corresponding tendency is their appearance in the mouth before the skin is affected. I do not have the space to discuss adequately the possibilities of such an association between the dental consultant and the dermatologist, for any that may be interested, there is a good deal of material in the discussion of a paper of Dr. Gilmer's by Dr. Wm. Pusey, *Journal of the American Dental Association*, Vol. 14, page 774.

All this may seem to have little to do with the relationship of the diagnosis of oral infection to the occurrence and distribution of systemic disease which might be considered by many of you to be either the only or the principal topic to be covered in this paper. No one can realize more clearly than I do the form of the question that is either directly or impliedly asked of the oral diagnostician in connection with this problem each time a case is referred to him. Is this arthritis, this iritis, this nephritis, this stomach ulcer, etc., caused by mouth infection? And this is precisely the form of question that he cannot answer. I feel confident that this is true in spite of belief in certain quarters that with the assistance of highly specialized and rather complicated laboratory tests such information may be supplied with reasonable accuracy. Whether that information is determined by the inoculation of susceptible animals with infected material from mouth lesions, or by the delicate complement deviation test, or by attempting to grow suspected organisms on the patient's whole blood, or by other devices, it is, I believe, only reliable to a degree that merely hints at the possibility of cause and effect. In any case, therefore, the problem is resolved into a matter of opinion and judgment, attributes that are cultivated only by long clinical experience. With such a precarious foundation, one would be foolhardy to claim such omniscience in oral diagnosis as to answer positively and without any reservation the questions propounded at the beginning of this paragraph.

The best that oral diagnosis has to offer is, therefore, qualified. It may be stated in any of the following forms. Infection is present in this mouth. Infection may be present in this mouth. It is probably not present. There is every reason to believe that infection is not present. In any case the removal of all demonstrable infection will be advised, and in no case will the elimination of organs or structures be countenanced where there is every reason to believe infection is not present. The attitude of the dental consultant toward the middle groups should, I believe, be determined by the exigency of the situation, guided by the belief that because the situation is desperate, treatment, though not logical, must be correspondingly radical. I see no other escape from this condition at the present time, as unsatisfactory as it may seem. To promise more is to discredit the whole proposition in the end. The temptation to venture opinions that are not justified by this form of reasoning is great, and some dental consultants are more susceptible to such influences than others and, more or less hypnotized by their altruistic enthusiasm, they issue prognostic promissory notes that are never redeemed.

In the final analysis the urgency and exigency of any given situation has to be determined not by the dental consultant but by the physician;

the former merely supplies all available information as to the condition of the oral structures and the medical consultant determines the type of treatment to be followed. It is my thought in this connection that the ideal dental consultant should be becomingly modest in this relationship and that, if in a certain sense, he knows too much about medicine, he will not function successfully.

The items listed and discussed in the preceding pages constitute a service that is distinctly worth while without any attempt to glorify such a specialized practice. I am strongly convinced

that the men who have been most successful in this field have arrived at this distinction because they have had great ability, fine character and an undivided interest in their work, and not merely because of the character and length of their formal training in educational institutions. We need fewer oral specialists in the field of medicine and more dentists who can work with physicians in an advisory capacity concerning such matters as have been discussed in this paper and, if you please, more physicians who know more about disease processes and the practice of medicine and less about dentistry.

A MODERN HEALTH TRIANGLE—PHYSICIAN, DENTIST, PATIENT

By ALFRED WALKER, D.D.S., NEW YORK, N. Y.

Read at the Joint Meeting of Organized Medical and Dental Professions at Hotel Pennsylvania, New York, November 30, 1931.

THE fact that this program has been arranged to include both physicians and dentists, and also the fact that it is only one of an increasing number of joint meetings of the two professions, indicates an accepted conviction that the mouth and body are very closely related. Therefore, it is unnecessary to elaborate on the need for co-operation between the medical man and the dentist. On the other hand, it seems to be in order to study the respective limitations of the two fields, as well as to consider the opportunities presented to the practitioners of each, to help the other.

The opportunities for co-operation in the two fields, are, perhaps, more numerous than is usually thought. Because of the great interest which has developed in recent years, in the study of focal infection diseases, it has come to be almost taken for granted that the physician sees in dentistry chiefly a means for rounding out his diagnosis in such cases as are believed to have a focal infection background. It is true that such cases are very numerous, and that the incidence of infections of the jaw is so great in our population that the diagnosis of these oral infections is very frequently needed.

We have heard so much about focal infection, and so much investigation, both clinical and laboratory, has been carried on, that we are apt to think there is little still to be learned in this field. However, this is far from being the case. Not only is the pulpless tooth still debatable, but we have many other types of possible foci about which neither the dentist, physician or research worker are in entire accord. The method of trial and error must still be used in a large number of cases, and this situ-

ation makes it clear that much further research in this field is needed. In this connection, it is interesting to refer to a paper by Dr. James L. Zemsky, read at the recent meeting of the American Dental Association, in which he urges that a clinical research on focal infection cases be carried on by general practitioners, who have an opportunity to keep in touch with their patients over a considerable period of years. Such research might also well be carried on in conjunction with a similar study by the general medical practitioner. As a means to such an end, I would urge that all medical records carry the name of the patient's dentist, and that all dental records carry the name of the patient's physician. I have been following this procedure for some time, and have found it to be most valuable.

In this respect, my practice has brought to light a most interesting and unexpected situation, which is that a considerable number of patients, when asked for the name of their physician, have stated that they have no regular family physician. Even those who gave the name of a physician are very often found not to have had a physical examination except when actually ill. Such a situation suggests at once an opportunity for co-operation of dentist and medical man, which may be of inestimable value to the patient.

However, opportunities for co-operation do not center solely in focal infection cases. Dentistry today is concerning itself most actively in nutrition. This is both from the standpoint of prevention of dental disease, but also in its treatment after it has made its appearance. Because of this interest stimulated by the research work of such investigators as McCollum, Mrs. Mellanby, Howe, Hanke and

MODERN HEALTH TRIANGLE—WALKER

others, the dentist is tempted, and in fact, urged from many quarters, to advise and actually prescribe for his patients along the lines of diet.

The research worker studying the fascinating subject of vitamins, for instance, and finding that he can produce certain well defined effects by dietary means, suggests to the dentist that by describing certain diets, he can control dental caries and periodontal disease.

Since most of the suggested diets are made up of foods which have been in use for a great many years, he feels no hesitation in recommending very definite diets to his patients.

Because of the natural limitations of his education and opportunities for evaluating various physical conditions, he is not in a position to go into this field quite as freely as might at first glance seem to be permissible.

I should like to sound a note of warning in this matter. I believe that the variation in individuals, which is so much greater than that in animals, makes it important that the question of diet should be left largely in the hands of the medical men. One reason for this word of caution is, that it may frequently happen that the diet, which is apparently suitable for correcting some dental condition, may have an adverse influence on some condition elsewhere in the body, and might, therefore, produce untoward effects. Carrying this thought a step farther, we find the dentist being urged not only by the research worker, but also by the manufacturers, to prescribe therapeutic preparations. These range from cod liver oil, which has been used in medicine for a great many years, to irradiated ergosterol, iron and calcium bearing compounds, and finally, to light therapy.

All of these may be accepted as having a definite value for the treatment of certain abnormal and diseased conditions of the body. That they may have harmful effects, especially in individual cases, is not so commonly recognized. Their use should certainly be in the hands of the medical man, or they, at least, should be prescribed after consultation with him. Exceptions to this dictum are, for instance, the use of ultra-violet radiation and similar therapy, by the dentist locally and for purely local treatment.

As an instance of the importance of seeking the co-operation of the physician in the field of therapy, for influencing the general nutritional status, I should like to refer to a recent article concerning researches on the effect of cod liver oil and Vitamin D concentrates, carried on in Norway. It was found that these preparations produced a perceptible and possibly harmful influence on the heart, as revealed in the electro-cardiogram. How

serious this influence is, has still to be determined, but it is obvious that the effect on individuals having heart defects, might be serious.

Dentists are becoming increasingly concerned over the condition of the teeth in pre-school children. These children show an alarming incidence of deep, penetrating caries, especially in the deciduous molars. The result is that when they reach the age for entering school, their teeth have frequently become hopelessly involved and require multiple extractions to relieve the child's system of the burden of focal infection. These extractions almost inevitably induce serious irregularity of the permanent teeth, leading to still further dental complications.

Not only is it difficult for the dentist to reach and successfully deal with the pre-school child in a satisfactory way, but even the best efforts of this kind frequently avail but little in checking the extension of the carious process. When we add to this the fact that such workers as Hesse state that their researches convince them that nutritional programs to be effective, must start practically at birth if not before, we see a most important argument as to why the physician should be consulted early in the life history of the individual, for the purpose of guarding against dental disease.

It is unnecessary for me to call the attention of physicians to the researches in nutrition, conducted by those who are so largely interested in dental health. I think it is in order to urge the physician to give this subject earnest thought whenever he is called in to advise the expectant mother, or to supervise the care of the newly born infant. Attention to nutrition at these times, should materially decrease, if not prevent, dental disease at a later period in life.

It may be of interest to refer briefly to an editorial in a recent issue of the Journal of the American Medical Association, in which it was noted that the saliva of some individuals contains anti-bodies effective against diphtheria and other diseases. This opens up an interesting field in its possible relationships to the question of both caries and periodontal disease. A study of immune individuals along this line, might well bring out information of great value.

Another field in which the assistance of the physician is needed, is that of periodontal disease, or so called pyorrhea. This disease manifests itself chiefly in the adult, and while its etiology is very frequently associated with purely local factors, many cases have an undoubted systemic background. Therefore, the assistance of the physician is urgently needed. However, it is a fact that in many instances,

the conventional physical examination, and even very searching blood examinations, have failed to reveal the systemic factor or factors. It is possible that this phase of diagnosis is still a subject for laboratory study, or in other words, that it is beyond the realm of routine medical practice as yet. However, it seems possible that a careful examination of a series of patients having marked susceptibility to periodontal disease, might reveal some condition common to all, which has heretofore been overlooked, but which might constitute the key to this very distressing and commonly occurring condition.

Having briefly reviewed the various relationships in which the interests of physician and dentist have a common ground in regard to the welfare of the patient, it remains only to suggest the limitations of each in regard to the management of their patients. The dentist should remember that he is working in a highly circumscribed field in whose local domain he may well expend all of his ingenuity and knowledge. He should be aware of the inter-relationships of the mouth and body, but when he wishes to influence mouth health by other than local measures, which may have an effect on other parts of the body as well, he should consult with the physician and place that part of his projected treatment in the hands of the medical man.

On the other hand, the physician should realize that the teeth and jaws are made up of structural elements quite different from those

of other parts of the body, and that the treatment of diseases in these tissues, even when it has a partially systemic etiology, is highly local in its nature. For example, efforts to treat periodontal disease by general therapy, are foredoomed to failure, and even the surgery of the mouth has such distinctly local peculiarities and consequences that it should be left entirely to the dentally trained practitioner. As an instance of the need for the limitation of fields of practice, it may be interesting to note that in the medical specialties such as ophthalmology, when a patient is found to have some local disturbance, which appears to be the result of a systemic condition, the ophthalmologist, although medically trained, refers his patient to an internist for physical examination, diagnosis and treatment.

In conclusion, I will say that the consideration of both dental and medical fields indicates that practitioners in each field, can be most helpful to each other, and that the best interests of their patients will be served by even a fuller co-operation and consultation than is customary at the present time.

I am not of the belief that it is necessary or desirable to attempt to define in detail, the limitations of each field, but believe that the training and experience of each practitioner, will enable him to say how far he should go in the treatment of his patients, and also when it is for the interests of the patient that he should call upon his colleague for advice and assistance.

MEETING OF PHYSICIANS AND DENTISTS

The official organizations of the Dentists of Greater New York held a three-day session early in the winter of 1931, the opening day of the sessions of 1931 being held on Monday, November 30. The program was under the joint auspices of the two District Branches of the Dental Society of the State of New York and the five county medical societies located within the limits of Greater New York. The program of the two other days was devoted to dental subjects.

The papers read on the opening day of the meeting were on subjects of mutual interest to both physicians and dentists, and were eleven in number—seven by physicians, three by den-

tists, and one by a practitioner who was a doctor both of medicine and dentistry. These eleven papers compose the scientific department of this issue of the Journal.

The dentists will repeat the plan of last year's meeting, and will conduct a four-day session beginning on Monday, December fifth, 1932, in the Hotel Pennsylvania. The program of the first day will be conducted jointly by the dentists and the physicians, with a program of equal interest to both.

The tentative program of the annual meeting of the Medical Society of the State of New York next Spring includes a joint session with the State Dental Society.

INSTITUTIONS AND INDIVIDUALS IN THE PRACTICE OF MEDICINE

Every sick person is an individualist, and demands the individual attention of his doctor. He likes to feel that his physician is constantly thinking over his condition, and is applying every device known to medical science, including that of deep personal concern. Cut off almost entirely from his accustomed associations, his activities are constantly restricted to the four walls of his

room, and a visit of his doctor becomes an expectant event in his life. His individuality is intensified by his sickness, and he demands an individual service to himself along three lines:

1. Release from worry and apprehension.
2. Relief from pain and discomforts.
3. Restoration to health and strength.

Impersonal science affords poor relief from

worry and apprehension when it takes frequent samples of blood for examination, and subjects the patient to uncomfortable tests and delays the answers for hours and days

The patient is dissatisfied with impersonal service when the doctor refuses to apply anodynes for pain, on the ground that they "mask the symptoms" of the diseases

Impersonal science may accomplish the restoration of health, but the patient is likely to say "I have a mighty good doctor, but I have got to do exactly as he says", and in his next sickness he will call a doctor with less science and more sympathy

When a person is dangerously sick, he lays aside his personal preferences and calls the highly scientific doctor; but in ordinary sickness he discredits skill and turns to the doctor who gives him personal satisfaction and relief from worry and apprehension. The personal influence of the physician is a real element in the treatment of the sick

The system of private practice which is dominant in the United States tends to apply a maximum amount of the personal influence to the doctor, for patients choose those physicians whom they like and will obey. On the other hand, the system is sometimes criticized because under it the distribution of medical service is often unequal, owing to the inequalities in wealth, nearness to hospitals, availability of specialists, and also the variance in the ability of the physicians, and also to the prejudice of the people

Social service workers and statisticians propose public clinics and various other forms of state medicine as sure means for applying the highest

grade medical service to all people. There are those who believe that a mass distribution of medical service is possible. These idealists omit to estimate the very great value of the personal influence of the doctor upon the sick patient. Moreover the idealists are wrong in believing that a high grade medical service can be bought off-hand. Civil service examinations often fail to estimate the personal qualities of the doctor, for they do not indicate his friendliness, his common-sense, and his devotion to duty

The Medical Society of the State of New York, and that of other states, are a unit in seeking to maintain the method of private practice as the basic system of distributing medical service. While the scientists recognize the necessity of State care of certain groups of patients, such as the insane and the feeble minded, yet it is seeking to prepare doctors to enter these fields in their private practice

While public clinics are sometimes necessary, as in giving diphtheria immunizations because of the ignorance of the people, yet departments of health are encouraging the people to obtain their treatments from their family doctors

The indigent sick are receiving excellent treatment from their family doctors where the county medical societies have made working agreements with the county commissioners of welfare

The experience of New York State indicates that the personal method of private practice will continue to be dominant, and that institutional, or State, medicine will prevail only in those co-operative forms of service which individual family doctors cannot give

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Doctors as Office-Holders This Journal of November, 1907, contains an editorial urging doctors to seek to hold office, because of the peculiar value of the service which they can give to the public along public health lines. The Journal says

"The science of medicine has brought about as far as it can the solution of the tuberculosis problem and the typhoid fever problem and a host of other similar problems which are as vital to the people as are the lives of their children, and in fact they are the same. Medicine has shown how these diseases may be exterminated. Now these matters are up to the State. That means their future develop-

ment is in the hands of politics. And shall our profession, after having hunted down the monster of typhoid, and gotten it at bay in its lair, cowed and at our mercy, desist from giving the *coup de grace* because the stroke must be applied with the bloody lance of politics? We need more doctors in our legislative chambers and in our executive offices. Medicine has long ago grown past the function of administering to those who perchance have fallen sick. It has become the most salutary department in the commonwealth, and we are not raising up men fast enough to administer its new offices. We may justly be accused of slothfulness in our duty to the people."

MEDICAL PROGRESS

Psychogenous or Habitual Vomiting.—Within the last few years, says Wilhelm Klimke, cases of "psychogenous vomiting" have repeatedly been admitted to the psychiatric and nerve clinic of Münster University, and the patients subjected to needless operative procedures on stomach and intestines, on the assumption that there must be recognizable changes in the organs of digestion. The result was always negative, because the cause lay in the region of the psyche, and required to be treated by suggestive therapy. Four illustrative cases are detailed, in which no organic changes could be discovered, but which were characterized by a reactive depression of spirits of mild degree, and a more or less psychopathic personality. Here the psychogenic factor was the constitution, and all the four patients were cured by appropriate treatment directed toward influencing the psyche. A dysphoric state of mind was common to all: the psychic experience had an unhappy content, which after long continuation broke down the psychic resistance. We know from physiology that the motility of the stomach is increased by the vagus, and diminished by the sympathetic, and that the afferent fibers for the act of vomiting run through the vagus. Slight irritation of the vagus may, accordingly, increase peristalsis and lead to spasms and complete breakdown of the pylorus. We must believe with Kraepelin that our movements of expression were originally movements of defense, and that ready vomiting, as for example in the dog, is a useful condition, a purposeful reaction, and that accordingly hysterical phenomena have been of use in the evolution of the human race. There are individuals in whom the vomiting center is more easily excited than in others. Kraepelin regards this as a sign of inhibition, of infantile immaturity. And since it is in psychopathic personalities that conditioned reflexes are long maintained, vomiting may serve in these individuals as an inhibitory reflex. In all such cases operative procedures must be avoided as useless. The only measures promising success, as these cases show, are psychotherapeutic influences.—*Deutsche medizinische Wochenschrift*, August 19, 1932.

Lobeline in Urticaria.—E. Moser writes to the *Schweizerische medizinische Wochenschrift* of September 24, 1932, that he has found great relief in his own person from lobeline in urticaria. He says he has suffered since childhood from repeated outbreaks of urticaria, but does not state the cause, whether allergic or not. Early in July of last year he suffered from a severe eruption of wheals, and having recently

noticed a recommendation of lobeline for the treatment of such an attack, he tried the remedy in dose of 0.01 (15/100 grain) hypodermically. Within half an hour the eruption disappeared and with it went the furious itching, and strange to say he has had no attack since. He has treated six patients for urticaria since that date with lobeline (15/100 grain for adults and 7/100 grain for a 12 year old boy), and with one exception successfully. The exception was the case of a woman who was cured of her first attack but suffered from repeated relapses. In looking up the literature of the therapeutics of urticaria the writer found lobeline recommended by A. Frank in the 1932 edition of his "Moderne Therapie."

Congenital Heart Disease in Children.—Although congenital affections of the heart constitute only about 1/5 of the cardiac diseases in children and although the diagnosis of this condition is extremely difficult and there is no specific treatment of it in any case, nevertheless it is by an attempt to make a differential diagnosis that we can learn more of the problems of the transmission of the defect and can give an intelligent prognosis. This is the consideration that has moved Dr. Howard B. Sprague to undertake a study of this subject. He discusses eight types of congenital heart disease which can usually be diagnosed. 1. *Ectopia cordis*. This is easily diagnosed. The duration of life is from one to fifteen months. 2. *Hypertrophy*. The diagnosis of this condition is made by exclusion, namely, by finding a generally enlarged heart in a young child, with no evidence of pericardial effusion or valvular disease. The maximum reported duration of life is four years, and the mean sixteen months. 3. *Dextrocardia*. The diagnosis is obvious if one is on the lookout for this anomaly, especially if it is part of a true situs inversus. When uncomplicated this condition is well tolerated. 4. *Roger's disease*. The diagnostic signs consist of a rough systolic murmur and thrill in the midsternal region or at the third and fourth intercostal spaces near the sternum. The oldest reported case in Abbott's series of autopsical studies was 44 years of age and the average 13¾ years. The author has had a case of this affection under observation for over seven years, in a girl of seventeen who is symptom-free and able to engage in mild athletics. 5. *Patent ductus arteriosus*. Mild degrees of this defect are not uncommon. The diagnosis is indicated by a continuous murmur and thrill maximal at the second left interspace near the sternum. The mean duration of life is 33¾ years, the oldest case recorded was in a man of sixty-six. 6. *Subaortic and*

aortic stenosis The presence of a systolic murmur and thrill at the second right interspace in an infant is strongly suggestive. The oldest reported case was in a person 58 years old, the average age being $22\frac{2}{3}$ years. **Tetralogy of Fallot** This combination of lesions is by far the commonest cause of cyanosis in congenital heart subjects surviving beyond the first few months of life. The average duration of life is $11\frac{1}{2}$ years. The oldest case on record was in a man dying at the age of $59\frac{3}{4}$ years. **Coarctation of the aorta** There is sometimes a narrowing of the aorta at the point where the ductus arteriosus leaves it. This leads to hypertrophy of the heart because of its forced contraction to overcome this stricture. A compensatory circulation is effected by anastomoses of the internal mammary and epigastric arteries and through the dilated intercostal vessels. The latter may at times be seen as strongly pulsating vessels over the chest wall, particularly at the back, and there results a pressure atrophy of the lower margins of the ribs which produces a characteristic scalloping in the x-ray plate. The x-ray also shows a small aortic knob. There may be a long systolic murmur over the upper part of the back. The condition has been observed up to the age of 92 years, but the average duration of life is $33\frac{1}{2}$ years.—*The New England Journal of Medicine*, September 22, 1932

Dental Sepsis and Cardiac Pain.—Donald Hall, writing in the *British Medical Journal*, September 24, 1932, II, 3742, cites a case which affords a striking example of the danger of the pulpless and painless tooth. The patient, an obese, flabby man, aged 52, when first seen in October, 1930, was in very poor condition. Since December, 1929, he had become progressively dyspnoic and for a month had been subject to attacks of retrosternal pain on exertion. The electrocardiogram gave abundant evidence of coronary thrombosis brought about by the massed effect of repeated minute infarctions. The outlook was discouraging, but as all his remaining teeth were carious or dead their removal was decided upon. They were extracted under local anesthesia, one at a time, while he was kept in bed on a high protein diet, with three tablets of calcium diuretin daily. When seen again, in June, 1931, he had lost three stone in weight and was wearing temporary dentures. His pain had nearly disappeared though he still had reminders of it out of doors when he walked quickly. In the house he could move with perfect comfort and had no pain on walking upstairs. The apex of the heart had moved in half an inch and was now in the fourth space, four inches from the mid sternal line. The electrocardiogram showed a striking change, having become physiological the only abnormality being a small bizarre QRS in Lead III of no pathological significance. He had since contin-

ued to do well and had resumed his professional work.

Harmful Effects of Nitroglycerin—In the course of a study in which therapeutic doses of nitroglycerin were given to 110 patient under direct observation, Samuel H. Prodigar and David Aymn observed alarming reactions to the drug in four instances. The reactions in these patients were similar in many respects. There was a marked and rapid fall in blood pressure, and the pulse rate was greatly diminished. The constitutional symptoms consisted chiefly of cold perspiration, weakness, restlessness, anxiety and pallor. In two cases the blood pressure became indeterminate and the pulse could not be palpated. In one of these heart block developed, and in the other the course of a cardiac infarction appeared to be unfavorably influenced. A record was made of the electrocardiographic changes which occurred during the reaction in these two cases. In the first case there occurred, in succession, sinus bradycardia, atrio-ventricular nodal rhythm, and finally, complete heart block. With the return of the blood pressure to a normal level, the heart block disappeared and an electrocardiogram taken several months later showed no evidence of it. In the other two cases there were marked slowing of the pulse rate, great drop in blood pressure, and severe constitutional symptoms. The authors point out that the fact that patients do not complain of unusual symptoms following the taking of nitroglycerin is not an indication that they have not experienced a toxic or unusual reaction. As a result of their experience they believe it should be made a rule in both private and hospital practice never to give nitroglycerin for the first time to patients without personal supervision, and observation of the blood pressure and pulse. Usually a small initial dose (1/200 to 1/300 of a grain) is given. Epinephrine is kept readily available. As the harmful effects of nitroglycerin may be easily overlooked in coronary thrombosis, the drug should be discontinued at the earliest indication of this condition.—*American Journal of the Medical Sciences*, October, 1932 CLXXIV, 4

The Treatment of Hypertony—Recently C. L. G. Pratt and I. Harris (*The Lancet*, Sept. 19 1931, p. 629) showed that the administration of certain drugs in cases of hypertony caused an increase of blood urea and non protein nitrogen a depression in the water excretion function, and a decrease in the cardiac reserve. Writing in *The Lancet*, September 10 1932, CLXXXIII, 5689, Harris reports the results of an attempt to compare certain methods of treating hypertony in relation to their action on blood chemistry. The patients were kept in bed with no treatment during the first week. During the second week collosol sulphur was injected, 3 c.c. daily. During the third

week six pints of water were given daily. In other cases a salt-free and sugar-free diet was taken in the second week, mainly carbohydrates in the third, and a pure meat diet in the fourth week. With the sulphur treatment reduction of blood pressure was accompanied by an accumulation of deleterious substances in the blood. The same phenomenon was observed when the pressure fell as the result of heart failure. This suggests that in cases of hypertony high blood pressure is needed to maintain a normal blood chemistry. Under the water treatment the blood pressure was definitely reduced, while the blood chemistry remained normal. The large amount of water lessens the viscosity of the blood and thus diminishes cardiac strain. It also enables the kidneys to excrete urea and allied substances more easily. A salt- and sugar-free diet reduced and a protein diet increased the blood pressure. The blood urea was somewhat increased under the salt- and sugar-free diet and somewhat diminished under the meat diet. The low blood urea after meat may be due to the diuretic properties of this substance. The increase of blood urea after a salt-free diet was by no means so pronounced and constant as when pressure-reducing drugs were given. After venesection there was a pronounced temporary reduction of blood pressure, while the blood chemistry remained normal. Harris concludes that it is undesirable to employ drugs for the purpose of reducing blood pressure. On the other hand, the drinking of large quantities of water should be encouraged. The diet should be of low protein content, and excessive amounts of salt should be avoided.

Coronary Thrombosis.—John Parkinson emphasizes the essential unity of angina pectoris and coronary thrombosis. He defines angina pectoris as a serious disease of the heart which is manifested by pain across the chest or at the sternum, often extending into the arms, and which is due to deficient coronary circulation or imperfect blood supply. There are two main varieties, but their specific pain differs only in intensity, and their pathology has a common factor in myocardial ischemia. When the pain is brief and depends on exertion, it is known as angina of effort; it rises from the ischemia due to localized arterial spasm. When the attack of anginal pain is unrelated to exertion and sufficiently prolonged, and complicated by symptoms of infarction, it is known as coronary thrombosis, and arises from the resulting necrotic ischemia. Between these two varieties all grades of angina pectoris are encountered, in the main depending on the severity and extent of the coronary disease and the effect on the myocardium—whether the ischemia is transient (arterial spasm) or permanent (infarction). There is thus no justification for the faulty classifications and confusing terminology which has grown up around the term “angina pectoris.”

Angina of effort may be initiated, complicated or terminated by coronary thrombosis. It is fairly inclusive of all cases of angina pectoris excluding coronary thrombosis, patients with spontaneous attacks of pain at rest being almost invariably subject to angina on exertion. Too much stress has been laid on the gravity of angina pectoris. Although it is inseparable from a risk of sudden death, this may be deferred for years. Too little attention has been centered on the anginal life and its management. Patients with angina often find life worth living and that they will live longer than is commonly supposed.

Once the diagnosis of coronary thrombosis is made, there must be quick relief from pain. Morphine is indispensable. Digitalis is indicated directly the signs of congestive heart failure appear. Amyl nitrite and trinitrin have little or no effect in allaying pain, and taking into account the fall in blood pressure they are contraindicated. Ample rest in bed is essential to favor healing of the infarct. Six weeks should be the minimum period in a case of coronary thrombosis. Convalescence should be as long as the patient can afford, at least three months, better still if he can abstain from work for six months.—*British Medical Journal*, September 17, 1932, ii, 3741.

The Physiology of Old Age.—According to Max Flesch, an old age symptom to which little if any attention has been called consists in a failure of the ability to regulate balance. He observed this in himself at the age of 75, when he could no longer ride a bicycle because of inability to find his balance in mounting, 4 to 6 attempts being necessary before he could get into his seat and travel. Also in riding over uneven places on hilly roads he had lost his old assurance and was compelled to go more slowly. There was no question of muscular fatigue, for the author at 81 can walk over a hilly country for 5 hours without the least fatigue. The disturbance seems rather to lie in the field of coordination with reference to control of balance. He had no discomfort from climbing 100 steps to a high tower, but could not, as formerly, gaze down over the country without a sense of dizziness. The first 20 steps of the descent, in the form of a winding staircase, he had to take one at a time, step by step; the next 60, built on square lines, presented no difficulty for the ordinary mode of descent, but again the last 20, in winding form, required the childish mode of taking stairs, notwithstanding all attempts at self-control. Once again upon even ground, all uncertainty disappeared. This disturbance evidently is not due to a peripheral involvement of the sense of balance. It appears rather to be the result of a central change of old age, which is felt first in the field of the gradual decline of memory for events and impressions of recent years. But there is no doubt that this disturbance of the sense of balance is the forerun-

ner and cause of many other old age symptoms. The slow walk and the bowed head of aged persons who are otherwise still robust is attributed by the author, on the basis of his own experience to this balance disturbance, which in his own case at last was the first symptom to appear—*Munchener medizinische Wochenschrift*, September 9, 1932

Treatment of Furuncles and Paronychias with Oxygen—After employing carbon dioxide treatment for some 6 years, C Salzmann states that in December, 1931, he began to use oxygen injections in suitable cases of furuncles and paronychias, and that he now makes use of this method in all cases of this kind and in other inflammatory dermatoses, with most gratifying results. The oxygen under high tension is conveyed from a steel tank through a rubber tube, by means of an apparatus for reducing pressure and measuring dosage, and introduced into the center of the furuncle through a sterile glass cannula of varying form and caliber, or a fine injection needle, according as the furuncle is already open or remains closed. If by cannula into a crateriform opening, it is blown in with the cannula under pressure of $\frac{1}{4}$, $\frac{1}{2}$, or 1 atmosphere, which is controlled according to the effect it produces. In the course of a day 5 to 10 such injections may be given, as needed. The tissue of the furuncle softens up with astonishing rapidity, so that a furuncle is emptied spontaneously within 24 to 48 hours, and not heard from again. Although painful, injections into the center of a furuncle cannot be compared from this point of view with incision. Soon after the first application the pains abate, the fever recedes, and the patient can sleep once more. In the emptied furuncle oxygen is injected again for a few times and so helps to remove the remainder of the necrotic tissue. No kind of medicament is necessary after this treatment. The furuncle promptly diminishes in size, the granulating base becomes dry and the secretion scanty. Oxygen assures a rapid healing process and only slight scars, such as no other form of therapy has left in its wake. Furuncles of the nose and upper lip especially are cured with remarkable speed and without any disagreeable complication. These injections produce an energetic resistance in the inflamed tissue observed by the author in all his cases, which now number about 100. The biologic action of oxygen in the tissues is not fully understood, and as yet no histological investigations of its action have been undertaken, so far as the author knows. While it has a mechanical hydraulic effect it is clear that it also acts biochemically upon the inflamed tissue. The defense of the inflamed tissue is increased by the absorption of oxygen

as is revealed clinically by the rapid breaking down of the inflammatory focus and the prompt arrival of a healing process—*Schweizerische medizinische Wochenschrift* August 27, 1932

Attempts at Treatment of Diabetics with Diathermy of the Pancreas—The accidental observation that patients who for one or another reason were subjected to diathermy of the dorso-lumbar region experienced an increased sense of hunger led Zoltan Rausch to assume that in such cases the pancreas had lain within the field of the diathermy current and that the stimulation of the function of the gland had resulted in a condition analogous to a hypoglycemic reaction. To test the validity of this supposition he applied diathermy to the pancreas of healthy subjects, and found that the blood sugar curve was lower than in those not so treated. He then carried his tests to diabetic subjects applying diathermy for $\frac{1}{2}$ -1 hour upon the region of the pancreas after determining the fasting blood sugar content. He used a 60 sq cm electrode upon the pancreas region and one of 100 sq cm upon the abdomen, suiting the intensity of the current to the tolerance of the patient. In most cases the blood sugar picture fell 0.02-0.04 mg per cent, in a few it rose a little instead, and in a small number it remained unaffected. It was also found that in certain cases a full hour of treatment was necessary to produce a result, while others responded better to a shorter application. Apparently the quality and the quantity of the reaction depend mainly on the extent to which the number of the Langerhans' islands has been reduced. Since this is dependent on the gravity of the diabetic condition, Rausch's further experiments were directed toward determining the influence of diathermy of the pancreas upon the glycolytic property of the blood of diabetic patients. The effect proved to be most favorable in light cases. Here it was possible under systematic treatment to increase carbohydrate tolerance considerably, and even to maintain it for a time without the aid of diathermy. In moderately severe cases the practical value of the treatment was less, for tolerance could only with difficulty be increased any further, insulin doses up to about 40 units being the largest that could be replaced by diathermy. The mechanism of the action of this form of diathermy can hardly be regarded otherwise than as an increase of insulin production. Diathermy causes a hyperemia in the pancreas which improves the oxygen supply of the cells and results in stimulation of glandular activity. This in turn increases the insulin content of the blood and raises the glycolytic capacity of the organism—*Deutsche medizinische Wochenschrift*, August 5, 1932

LEGAL

MALPRACTICE—LIABILITY FOR EXPERIMENTAL DIAGNOSIS AND TREATMENT

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

The law imposes the duty upon a physician to keep abreast of the times and in his treatment of his patient to use the approved methods in general use among competent practitioners in the locality where he practices. While, however, the law places upon the physician the duty of keeping abreast of the times, it does not permit him to experiment upon his patient; and if he uses means and methods in his treatment which are not "approved" methods and injury results to the patient, the law holds him responsible for the consequences of such experimentation. A malpractice action which recently arose in one of the Pacific Coast States, brought against a duly licensed osteopath, illustrates this principle although the case is an extreme one, and presents a state of facts which should be of interest to the medical profession. In this editorial we shall detail the facts and circumstances so that the ruling of the court may be fully appreciated.

A child about nine years of age had complained of pain, and her mother called in a doctor who diagnosed her condition to be that of osteomyelitis. He advised that the child be taken to a hospital, x-rays taken and an operation performed. It seemed that the child had shown talent as a toe-dancer and the mother, wishing to avoid the possibility of a scar being left on the child's leg from an operation, sought to remedy the condition without operative procedure. A neighbor referred her to a certain Dr. T who was a duly licensed osteopath known to treat various ailments without surgery.

The neighbor communicated with the said Dr. T, asking him whether he could treat the case of a bone ailment of a nine-year old girl. Word was given back by the said osteopath to the effect that in order to determine whether he could treat the case, he required a specimen of the child's handwriting. This was given to Dr. T and with it he proceeded to make his diagnosis, using what he called a radio-diagnostic machine. The said machine was a mechanism contained in a bakelite covered box equipped with several dials, several of which were for measuring the intensity of the disease, and one of which was used for "turning on the different kingdoms, such as animal,

vegetable, mineral, electrical and ether waves." From a terminal on the machine an electrode was provided to be placed over the patient's solar plexus, from which an "emanation" from the patient was supposed to pass to a condenser in the machine, there to be amplified some thousands of times and sent on from the machine by another electrode applied to the solar plexus of a healthy individual. The idea seems to have been that the healthy individual would react in such a way that Dr. T, manipulating the dials and making certain tests with a circular rubber rod, could ascertain the severity of the disease. Each disease apparently was supposed to have a definite wave length and could be detected by a reading of the dials.

In using this machine Dr. T made a preliminary diagnosis by connecting up the machine with a metal plate, against which was placed the paper with the child's handwriting. Dr. T was assisted by his wife, Mrs. T, who, after the machine had been connected to the paper, bared her abdomen. Dr. T applied the electrode and stroked Mrs. T's abdomen with his rubber rod and worked the dials on the "radio." Mrs. T then exclaimed that she felt a pain in the left leg and hip. Dr. T thereupon declared that the child should be brought to him for immediate treatment which would not require an operation.

The child was brought to his office and a further "diagnosis" was made. Electrodes from the machine were placed against the child's neck, stomach and leg, and again Mrs. T bared her abdomen and Dr. T, operating the machine, rubbed the rubber rod over it. Mrs. T was then heard to state: "Yes, this is the pain in the leg. It is a very bad pain." Dr. T advised the child's mother that his diagnosis indicated to him that he could cure her condition in a very few days without operation. He declared that the ailment was meningitis, the germs of which instead of settling in the patient's back had lodged in the leg. The mother of the child turned her over for treatment to Dr. T.

The next step undertaken was to determine what kind of applications were to be used on the child's leg and again the radio device was used in a similar manner, as a result of which

Dr. T determined that hot vinegar should be applied to the affected parts of the child. The child remained in the care of Dr. T and his wife for three weeks. The chief treatment throughout was exposure to the "radio" machine for three or four hours daily. In addition to said treatment the child was placed in what was described as a "vit-o-net or magnetic blanket" for a considerable period during which the patient perspired freely. After several days of treating the child, Dr. T and his wife went on a vacation leaving the child under the care of a Dr. P, who continued the "radio" treatment with the aid of a nurse upon whose abdomen the rubber rod was applied as before. This same device was also used to determine what foods the child should be given and it was read to indicate plums, pears and grapes and to contraindicate oranges.

The child's condition failed to improve as a result of the extraordinary treatment which she received, but on the contrary the pain increased and the swelling spread throughout the left leg. Finally the mother became alarmed and took the child away from Dr. T and his "radio" treatment and consulted another doctor. Examination revealed that the osteomyelitis had become so far advanced that the leg required amputation in an attempt to save the child's life. An orthopedic specialist was called into the case and the leg was amputated near the knee. Drainage was provided and two subsequent operations were found necessary to clear up the infection. After a long period of hospitalization the child was brought out of danger, but she remained an invalid for months thereafter.

Suit was subsequently instituted on behalf of the infant against the osteopath, charging him with negligence and unskillfulness in the treatment of the child, and seeking to recover large damages by reason thereof. The case was tried and the jury found against the defendant in the sum of \$30,000. An appeal was taken which resulted in an affirmance of the judgment against the said Dr. T in the sum of \$20,000, the court stating that in its opinion the verdict rendered by the jury was somewhat excessive although there could be no reversal on the question of liability.

One of the points urged to the appellate court was that the record showed that the defendant had been employed to render treatment to the infant by his "radio" method, and that having done so to the best of his ability he should escape liability. The court, in determining against this contention, said in part:

"When one, with his own inventions, holds himself out as a healer of diseases and accepts employment as such, he must be held to the duty of reasonable skill in the practice of his profession, and when he seeks fields of experimentation he will be held accountable for any damages proximately caused by the unskillful treatment of his patients.

"This court passes no judgment on the theory of his profession, the source from whence it came, nor the appliances with which he works. With these we have no concern, but rather look to the results. The law holds him responsible if he does his work unskillfully although he does the best he can. He assumes the risk of the quality and accuracy of his genius or inventions. On the same principle one who holds himself out as a medical expert and accepts employment as a healer of diseases but who relies for diagnoses and remedies on some mechanical invention of his own, which invention is unknown to all schools of medical science, in like manner takes the risk of the quality and accuracy of such mechanical invention. If these move so imperfectly or inaccurately that he fails to treat the patients with reasonable skill he is liable for the consequence. The law takes cognizance of the question: Did the practitioner render the services he undertook in a reasonable manner? That question as applied to the appellant, the Jury, on sufficient proofs, we believe, have answered in the negative.

"* * * Simply because a person claims or pretends to have invented a machine for diagnostic and curative purposes which is not known or recognized by any school of medical science, which machine possesses certain powers of healing peculiarly within the knowledge of the inventor, is no reason why other persons who know nothing of the workings of such machine but who have knowledge acquired from education, experience and practice, are not competent to judge whether the treatment administered is negligently or carelessly done. Otherwise, as we have heretofore indicated, any non-professional person might undertake to treat certain disorders, and if appellant's position be correct in law, it matters not how carelessly or negligently his acts were performed because no one could be obtained of the same pretensions to testify with respect to such treatment and the injured person would be without remedy.

"This contention we think untenable and has been so held by other jurisdictions."

FEE SPLITTING

At the September, 1932, meeting of the Executive Committee of the Medical Society of the State of New York, the resolution which forms the subject-matter of the following letter was brought up for discussion. Several members of the Committee raised the question as to whether this resolution violated Section 32 of the Prin-

ciples of Professional Conduct of the Medical Society of the State of New York. The matter was referred by the Executive Committee to Legal Counsel for an opinion. The opinion was duly rendered to the Executive Committee, which then ordered the same to be published in the NEW YORK STATE JOURNAL OF MEDICINE.

June 28, 1932.

Dr. Daniel S. Dougherty, Secretary.
Medical Society of the State of New York,
2 East 103rd Street, New York City.

Dear Dr. Dougherty.

At the meeting of the Executive Committee held on June 16, 1932, the following excerpt from the report of the Reference Committee of the House of Delegates on the report of the Committee on Medical Economics was referred to me for opinion:

"In that vast majority of families where there is a limit of ability to compensate professional service if there has been a bona fide participating service and responsibility, then with the knowledge of the patient, the lump sum which is possible should be divided between the participants according to the respective bona fide service rendered by each." (Journal, June 15, 1932, page 751.)

In my opinion, the quoted excerpt violates the letter and the spirit of Section 32 of the Principles of Professional Conduct of the Medical Society of the State of New York adopted June 1, 1931. Section 32 provides as follows:

"Physicians shall not give nor offer nor shall they undertake or promise to give, either directly or indirectly, any gift, gratuity, commission or bonus in consideration of or in return for the referring, recommending or procuring of any patient for medical, surgical or other treatment or in consideration of or in return for the referring, recommending, or procuring of any per-

son, specimen or material for diagnostic or other study or work; nor shall any physician request, solicit, accept or receive any such gift, gratuity, commission or bonus."

The above quoted Section was framed and designed to prevent "fee-splitting," whether directly or indirectly. In my opinion, the recommendation under consideration would permit "fee-splitting" to flourish under the color of legal sanction from the Medical Society of the State of New York.

The vice of "fee-splitting" is not cured by disclosure to the patient that the fee is to be divided, nor does Section 32 of the Principles of Professional Conduct sanction the division of fees with the consent of the patient.

It is true that the excerpt in question provides that the total sum be divided according to the respective bona fide service rendered by each physician, but this only provides a loophole which would certainly be taken advantage of by those addicted to "fee-splitting." This certainly would permit "fee-splitting" under the claim that it was done with the consent of the patient and for bona fide service rendered.

I believe that approval of the excerpt in question would constitute an extremely dangerous precedent. In my opinion, it is repugnant to and in conflict with the aims and purposes of Section 32 of the Principles of Professional Conduct.

With kind regards, believe me,

Faithfully yours,

(Signed) LORENZ J. BROSNAN.

NEWS NOTES

FIRST DISTRICT BRANCH

The twenty-sixth annual meeting of the First District Branch of the Medical Society of the State of New York was held on Friday, October 14, 1932; in the Rockland Country Club House, Sparkhill, Rockland County, New York.

The First District is composed of three county societies of Greater New York—Bronx, New York and Richmond—and four county societies in the lower Hudson River valley—Rockland, Orange, Westchester and Dutchess-Putnam. (See map in Journal of Oct. 1, page 1137).

The President, Dr. Charles D. Kline, of Nyack, presided, and Dr. Isidore J. Landsman, of Bronx County, was secretary. About one hundred members were in attendance. The morning was given over to a golf tournament. Luncheon was served at noon in the Country Club, after which representatives of the State Society gave brief addresses.

Dr. Chas. Gordon Heyd, President, described the economic condition of the family doctor and the growing cost of government resulting from paternalistic services, including those along medical lines.

Dr. Orrin Sage Wightman, Editor-in-Chief of the Journal, emphasized the value of the New York State Journal of Medicine as a record of the activities of physicians and their organizations. If doctors read the Journal faithfully, they would find an answer to most of their perplexing problems.

Dr. James E. Sadlier, Chairman of the Com-

mittee on Public Relations, explained that the objective of the Committee is to demonstrate how doctors may assume leadership in all forms of medical service, both private and public. The members of the Committee are always available to advise county societies in the solution of their local problems.

A telegram was sent to Dr. D. S. Dougherty, Secretary of the State Society, wishing him a speedy recovery from his illness.

The following officers were elected for the next two years to take office at the close of the annual meeting in 1933.

President, C. Knight Deyo, M.D., Poughkeepsie.

First Vice-President, Samuel J. Kopetzky, M.D., New York.

Second Vice-President, Edward C. Podvin, M.D., Bronx.

Secretary, Isidore J. Landsman, M.D., Bronx.

Treasurer, John T. Howell, M.D., Newburgh.

The scientific program was carried out as follows:

"Neurogenic Basis for Abdominal Sign Symptoms," Edward M. Livingston, M.D., New York.

"The Adrenals in Health and Disease," Max A. Goldzieher, M.D., Brooklyn. (See N. Y. State Jour. of Med., Sept. 1, 1932, page 1001).

"Compulsory Health Insurance Abroad," Emil Koffler, M.D., Bronx. (See N. Y. State Jour. of Med., April 15, 1932, page 437.)

FOURTH DISTRICT BRANCH

The twenty-sixth annual meeting of the Fourth District Branch of the Medical Society of the State of New York, was held on Tuesday and Wednesday, October 11th and 12th, 1932, in Schenectady, N. Y.

The Fourth District consists of ten county societies, extending from the Mohawk River to the St. Lawrence and Lake Champlain. (See map in Journal of October 1, 1932, page 1137). This District has 512 members of whom 100 were present.

The President, Dr. Frank vander Bogert, presided, and Dr. Sylvester C. Clemens, of Gloversville, was secretary.

The program of the morning session consisted of a series of clinics and demonstrations at the Ellis Hospital. An instrument for

measuring the temperature of the skin was shown. An important use of the instrument is the determination of the site of a thrombus in the leg, by taking the temperature at various points. The thrombus is located at the level at which the temperature of the skin begins to show a decided drop.

There was a demonstration of the Emerson respirator, a new instrument for maintaining artificial respiration for days at a time, as in infantile paralysis.

A skin clinic was held by Dr. A. B. Van Vranken and Dr. C. F. Rourke, both of Schenectady.

Dr. F. J. Garlick showed a case of hemato-genous jaundice, and one of polycythemia, or an increase of the red blood cells.

QUALIFICATIONS FOR HEALTH OFFICERS

The Public Health Council of the State, at its meeting on May 20, 1932, enacted new qualifications for local health officers.

These qualifications classify all local health officers in two grades known as Grade I and Grade II, and apply to all appointments made after June 1, 1932.

To be appointed a county health commissioner or a health officer of a city over 50,000 population the candidate must have the qualifications specified for Grade I.

Candidates for appointment as health officer of a town, village, consolidated health district or a city with population less than 50,000 must have the qualifications specified for Grade Two.

The qualifications for Health Officer Grade I, require not less than four years of full-time experience in a responsible public health position; or not less than two years of such experience and a course in public health approved by the Public Health Council of at least one scholastic year in residence, or other combination of experience and training deemed by the Public Health Council to be the equivalent.

Physicians who have fulfilled any of the four following requirements may qualify for appointment as Health Officer Grade Two:

(a) If they have completed *before* June 1, 1932, a course in public health of less than a year in residence approved by the Public Health Council, and have had four years of experience as a part-time health officer.

(b) If they successfully complete a course in public health of less than a year in residence that has been approved by the Public Health Council as qualifying for this Grade *after* June 1, 1932. This and the preceding paragraph refer to correspondence courses and short post-graduate courses that have been approved.

(c) If they have completed an *undergraduate* course in public health that has been approved by the Public Health Council as qualifying for local health officer this grade.

(d) If they have had other experience, training, and education in public health work which in the opinion of the Public Health Council is the equivalent of any of the above, they may be considered as qualified.

The Public Health Council may waive the qualifications as to any proposed appointment under special circumstances specified in writing.

The Albany Medical College is cooperating with the New York State Department of Health in providing a course in Public Health specified by the Public Health Council as qualifying for Health Officer Grade Two. The course will consist of twenty reading and study assignments which physicians can pursue at their own offices. Once each month, or eight times during the course, a full day will be spent with the District State Health Officer, or the director of the course. At these conferences practical application will be made of the material contained in the reading assignments. The second week of June will be a residence week in which all candidates will meet for a full week of conferences, discussions, and demonstrations.

A special committee of the Public Health Council consisting of Dr. F. F. Russell, Dr. Thomas Parran, Jr., and Professor Henry N. Ogden met with the Deans and the Professors of Public Health of all the medical schools in New York State at the State Office Building in New York City on September 20, 1932. The purpose of the meeting was to endeavor to formulate plans for courses in Public Health for undergraduate medical students so that, when graduated, they would be eligible for appointment as Health Officer Grade Two.

A continuation committee was appointed to give the subject further study and formulate recommendations. These will be considered at an early meeting of the Public Health Council.

PAUL B. BROOKS,
Deputy Commissioner of Health.

COLUMBIA COUNTY

The annual meeting of the Columbia County Medical Society was held at Hudson, on October 5, 1932.

The following officers for the year 1933 were elected:

President, L. Van Hoesen, Hudson.
Vice-President, F. C. Maxon, Chatham.
Sec'y-Treasurer, H. C. Galster, Hudson.
Censors, W. D. Collins, Hudson; H. J. Noerling, Valatie; C. L. Nichols, Philmont; E. Niver, Hillsdale; S. V. Whitbeck, Hudson.
Delegate to State Society, S. J. Post, Philmont,

Alternate to State Society, L. J. Early, Hudson.
Dr. John Dardess of Chatham was elected to membership.

During the afternoon session two scientific papers were presented:

Dr. Arthur F. Holding of Albany gave a paper on the use of the bronchoscope in the treatment of pulmonary disease.

Dr. H. C. Galster described the Vienna Clinics, and related his experience while attending them.

L. VAN HOESEN, M.D., *Secretary.*

NEWS NOTES

FIRST DISTRICT BRANCH

The twenty-sixth annual meeting of the First District Branch of the Medical Society of the State of New York was held on Friday, October 14, 1932, in the Rockland Country Club House, Sparkhill, Rockland County, New York.

The First District is composed of three county societies of Greater New York—Bronx, New York and Richmond—and four county societies in the lower Hudson River valley—Rockland, Orange, Westchester and Dutchess-Putnam. (See map in Journal of Oct. 1, page 1137).

The President, Dr. Charles D. Kline, of Nyack, presided, and Dr. Isidore J. Landsman, of Bronx County, was secretary. About one hundred members were in attendance. The morning was given over to a golf tournament. Luncheon was served at noon in the Country Club, after which representatives of the State Society gave brief addresses.

Dr. Chas. Gordon Heyd, President, described the economic condition of the family doctor and the growing cost of government resulting from paternalistic services, including those along medical lines.

Dr. Orrin Sage Wightman, Editor-in-Chief of the Journal, emphasized the value of the New York State Journal of Medicine as a record of the activities of physicians and their organizations. If doctors read the Journal faithfully, they would find an answer to most of their perplexing problems.

Dr. James E. Sadlier, Chairman of the Com-

mittee on Public Relations, explained that the objective of the Committee is to demonstrate how doctors may assume leadership in all forms of medical service, both private and public. The members of the Committee are always available to advise county societies in the solution of their local problems.

A telegram was sent to Dr. D. S. Dougherty, Secretary of the State Society, wishing him a speedy recovery from his illness.

The following officers were elected for the next two years to take office at the close of the annual meeting in 1933.

President, C. Knight Deyo, M.D., Poughkeepsie.

First Vice-President, Samuel J. Kopetzky, M.D., New York.

Second Vice-President, Edward C. Podvin, M.D., Bronx.

Secretary, Isidore J. Landsman, M.D., Bronx.

Treasurer, John T. Howell, M.D., Newburgh.

The scientific program was carried out as follows:

"Neurogenic Basis for Abdominal Sign Symptoms," Edward M. Livingston, M.D., New York.

"The Adrenals in Health and Disease," Max A. Goldzieher, M.D., Brooklyn. (See N. Y. State Jour. of Med., Sept. 1, 1932, page 1001).

"Compulsory Health Insurance Abroad," Emil Koffler, M.D., Bronx. (See N. Y. State Jour. of Med., April 15, 1932, page 437.)

FOURTH DISTRICT BRANCH

The twenty-sixth annual meeting of the Fourth District Branch of the Medical Society of the State of New York, was held on Tuesday and Wednesday, October 11th and 12th, 1932, in Schenectady, N. Y.

The Fourth District consists of ten county societies, extending from the Mohawk River to the St. Lawrence and Lake Champlain. (See map in Journal of October 1, 1932, page 1137). This District has 512 members of whom 100 were present.

The President, Dr. Frank vander Bogert, Glenside, and Dr. Sylvester C. Clemens, of Gloversville, was secretary.

The program of the morning session consisted of a series of clinics and demonstrations at the Ellis Hospital. An instrument for

measuring the temperature of the skin was shown. An important use of the instrument is the determination of the site of a thrombus in the leg, by taking the temperature at various points. The thrombus is located at the level at which the temperature of the skin begins to show a decided drop.

There was a demonstration of the Emerson respirator, a new instrument for maintaining artificial respiration for days at a time, as in infantile paralysis.

A skin clinic was held by Dr. A. B. Van Vranken and Dr. C. F. Rourke, both of Schenectady.

Dr. F. J. Garlick showed a case of hemogenous jaundice, and one of polycythemia, or an increase of the red blood cells.

Luncheon was served at the Hospital at 1 p.m.

The program of the afternoon session, which was also held at the Hospital, was as follows:

1. "The Hospital Management of Diabetes," Howard I. Grice, M.D., Resident Physician, Ellis Hospital, Schenectady. Discussion by Dr. L. F. Schiff, Plattsburg.

Among the interesting exhibits shown by Dr. Grice was that of a comparison of lumps of sugar with other foods which equalled them in caloric value.

2. "Treatment of Obstructing Lesions of the Prostate," Joseph F. McCarthy, M.D., New York City.

3. "Acute Appendicitis," A Clinical Analysis of 320 Cases, Denver M. Vickers, M.D., Mary McClellan Hospital, Cambridge, N. Y.

4. "Head Injuries," Lorimer J. Austin, M.D., Kingston, Ontario.

A dinner was held in the evening in the Hotel Van Curler at seven o'clock, after which representatives of the State Society were introduced.

Dr. Chas. Gordon Heyd, President, spoke briefly on the mounting costs of social service, especially those in which public health is associated.

Dr. Orrin Sage Wightman, Editor-in-Chief, called attention to the efforts of the officers and committeemen of the State Society to make the Journal represent all forms of progressive thought of a medical nature.

The subject of "Iroquois Medicine" was presented in a vivid manner by Dr. Eric Stone of Providence, R. I. Dr. Stone showed lantern slides illustrating the means and methods used by Indians, including flint knives, herbs, counter irritation, diaphoretics, diuretics, cathartics, and emetics. These physical methods were used in ordinary cases, but when they failed, the medicine man resorted to dances and incantations.

Dr. Lorimer J. Austin gave an address on the subject of the 18th Century Physician. Dr. Austin illustrated his talk by lantern slides of pictures by William Hogarth, an English caricaturist, painter, and engraver, 1697-1764, whose pictures revealed the office equipment of the 18th Century doctor, as well as that of the quack—such as a crocodile suspended from the ceiling with a lantern issuing from his side.

The addresses by Dr. Stone and Dr. Austin were excellent examples of cultural work—that of a doctor's avocation along lines relating to medicine.

Wednesday morning was devoted to a demonstration of recent scientific developments in the electrical line, held in Rice Hall of the Research Laboratories of the General Electric Company. This exhibit was of a striking interest to physicians, especially that part which had a direct bearing on medicine.

The Schenectady meeting was highly successful, owing to the breadth and variety and practical value of its program.

FIFTH DISTRICT BRANCH

The twenty-sixth annual meeting of the Fifth District Branch of the Medical Society of the State of New York was held on Tuesday, October 4, 1932, in the Elks Club, Oneida, N. Y. This District is composed of the seven counties of Herkimer, Jefferson, Lewis, Madison, Oneida, Onondaga and Oswego, located in the north central part of the State. (See map on page 1137 of the October first Journal). The District contains 762 members of whom about 120 attended the meeting. The presiding officer was Dr. E. R. Evans of Utica, President, and Dr. F. C. Sabin, of Little Falls, was secretary. Luncheon was served in the Hotel Oneida, after which officers of the State Society were introduced. The guests were welcomed by Dr. D. H. Conterman, President of the Medical Society of the County of Madison, under whose auspices the meeting was held.

Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, called attention to the breadth of the work of the State Society, especially the evolution of scientific medicine, and the development of

methods of the practice of civic medicine by the medical profession as a group.

Dr. Frederick H. Flaherty, President-elect of the State Society, spoke of the growing consciousness of the individual members regarding their responsibility for the reputation of the medical profession as advisers of the municipality in distinction from the individual citizens.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education spoke of the value of the graduate lectures offered to the members through the county societies, and urged the local officers to indicate their preferences and wishes regarding both the subjects and the lecturers.

Dr. O. S. Wightman, Editor-in-Chief, called attention to the nine departments of the Journal, and the special value of each division to every member of the Society. He stressed the importance of reports of the District Branch meetings, and the recording of the activities of the constituent county societies.

Dr. T. Wood Clarke, of Utica, discussed the present-day status of allergic conditions, and

reviewed each phase of the subject in a concise form that could be easily understood by the family doctor. The paper was discussed by Dr. William A. Groat and Dr. Joseph R. Wiseman, both of Syracuse, and Dr. George M. Fisher, of Utica.

Dr. Harold E. B. Pardee, of New York City, correlated the symptoms and pathology of arteriosclerotic heart disease, and illustrated his points with lantern slides. He traced the development of the disease from the time of the involvement of the coronary artery to the stage of thrombosis and the resulting muscle degeneration, and closed with a discussion of the electrocardiogram. The paper was a general review of the modern concept of heart disease. Discussion was opened by Dr. C. D. Post of Syracuse.

Three papers were read at the afternoon session as follows:

"Surgical Measures for the Relief of Intractable Pain," Byron Stookey, M.D., Neurological Institute, New York City.

Dr. Stookey discussed an operation known as "cordotomy" performed for the purpose of interrupting the fibers of temperature and pain sensation in the spinal cord in cases where there existed no other possible method of relief of pain. He showed slides of sections of the spinal cord illustrating the group of fibers

under discussion and showing the changes in the cord after section of these fibers. Such an operation was shown to be useful in carcinoma and other neoplasms which have become inoperable and are causing pain. Also in *tabes dorsalis*, in eroding abdominal aneurisms and similar conditions. Further discussion of Dr. Stookey's paper was opened by Dr. F. S. Wetherell of Syracuse and continued by Dr. Eugene Boudreau of Syracuse and Dr. Hyser W. Jones of Utica.

"Some Indications for Plastic Surgery," Leon E. Sutton, M.D., Syracuse, N. Y.

Dr. Sutton's paper was an exceedingly interesting one with excellent slides showing the various steps and procedures in the relief of the deforming scars and other plastic work. The discussion of Dr. Sutton's paper was opened by Dr. E. H. Carpenter of Oneida.

"Study of Surgical Complications—Incidence and Treatment," Murray MacG. Gardner, M.D., and Howard N. Cooper, M.D., Watertown.

The third paper was read by Dr. Cooper and referred to a number of common and rare post-operative complications. It met with a very favorable reception by the audience and provoked considerable discussion. The discussion was opened by Dr. Thomas P. Farmer of Syracuse who was followed by a number of others including Dr. Wetherell of Syracuse.

EIGHTH DISTRICT BRANCH

The Eighth District Branch of the Medical Society of the State of New York held its twenty-seventh annual meeting on Thursday, October 6, 1932, in "The Barn," Le Roy, N. Y., with the first Vice-President, Dr. F. J. Schnell, North Tonawanda, in the chair, and 150 members present.

A noon-day luncheon was served, after which representatives of the State Society were introduced.

Dr. Frederick H. Flaherty, President-elect, called attention to the opportunities of the State Society to demonstrate the achievements and ideals of the medical profession in the sight of the people.

Dr. W. D. Johnson, past-President, called upon every member to practice the best possible brand of medicine and surgery, in order to forestall the assumption of leadership by lay organizations, who plan to substitute impersonal mass treatments in place of the friendly contact of the family doctor.

Dr. O. S. Wightman, Editor-in-Chief, urged the members to take a personal interest in the Journal, because it represents the aims and aspirations which dominate every scientific physician in the land.

Dr. Harry R. Trick, Trustee, spoke of the coordination of the activities of the State Society through the Trustees.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education, spoke of the graduate courses of instruction offered to doctors and the public health activities which the people expect the medical societies to foster.

A minute's silence, with the members standing, was observed in memory of Dr. John A. Card, who died on June 28th while Speaker of the House of Delegates.

The scientific program consisted of four papers, as follows:

"Carcinoma of Colon and Rectum," Frank H. Lahey, M.D., Boston, Mass.

"Lessons from Diabetic Children for Diabetic Adults," Elliott P. Joslin, M.D., Boston, Mass.

"Medical Economics," Charles H. Goodrich, M.D., Chairman, Committee on Medical Economics, Medical Society of the State of New York.

A moving picture, showing the "Mechanism of the Heart Beat and Electro-Cardiography," L. M. Hurxthal, M.D., Boston, Mass.

QUALIFICATIONS FOR HEALTH OFFICERS

The Public Health Council of the State, at its meeting on May 20, 1932, enacted new qualifications for local health officers.

These qualifications classify all local health officers in two grades known as Grade I and Grade II, and apply to all appointments made after June 1, 1932.

To be appointed a county health commissioner or a health officer of a city over 50,000 population the candidate must have the qualifications specified for Grade I.

Candidates for appointment as health officer of a town, village, consolidated health district or a city with population less than 50,000 must have the qualifications specified for Grade Two.

The qualifications for Health Officer Grade I, require not less than four years of full-time experience in a responsible public health position; or not less than two years of such experience and a course in public health approved by the Public Health Council of at least one scholastic year in residence, or other combination of experience and training deemed by the Public Health Council to be the equivalent.

Physicians who have fulfilled any of the four following requirements may qualify for appointment as Health Officer Grade Two:

(a) If they have completed *before* June 1, 1932, a course in public health of less than a year in residence approved by the Public Health Council, and have had four years of experience as a part-time health officer.

(b) If they successfully complete a course in public health of less than a year in residence that has been approved by the Public Health Council as qualifying for this Grade *after* June 1, 1932. This and the preceding paragraph refer to correspondence courses and short post-graduate courses that have been approved.

(c) If they have completed an *undergraduate* course in public health that has been approved by the Public Health Council as qualifying for local health officer this grade.

(d) If they have had other experience, training, and education in public health work which in the opinion of the Public Health Council is the equivalent of any of the above, they may be considered as qualified.

The Public Health Council may waive the qualifications as to any proposed appointment under special circumstances specified in writing.

The Albany Medical College is cooperating with the New York State Department of Health in providing a course in Public Health specified by the Public Health Council as qualifying for Health Officer Grade Two. The course will consist of twenty reading and study assignments which physicians can pursue at their own offices. Once each month, or eight times during the course, a full day will be spent with the District State Health Officer, or the director of the course. At these conferences practical application will be made of the material contained in the reading assignments. The second week of June will be a residence week in which all candidates will meet for a full week of conferences, discussions, and demonstrations.

A special committee of the Public Health Council consisting of Dr. F. F. Russell, Dr. Thomas Parran, Jr., and Professor Henry N. Ogden met with the Deans and the Professors of Public Health of all the medical schools in New York State at the State Office Building in New York City on September 20, 1932. The purpose of the meeting was to endeavor to formulate plans for courses in Public Health for undergraduate medical students so that, when graduated, they would be eligible for appointment as Health Officer Grade Two.

A continuation committee was appointed to give the subject further study and formulate recommendations. These will be considered at an early meeting of the Public Health Council.

PAUL B. BROOKS,
Deputy Commissioner of Health.

COLUMBIA COUNTY

The annual meeting of the Columbia County Medical Society was held at Hudson, on October 5, 1932.

The following officers for the year 1933 were elected:

President, L. Van Hoesen, Hudson.
Vice-President, F. C. Maxon, Chatham.
Sec'y-Treasurer, H. C. Galster, Hudson.
Censors, W. D. Collins, Hudson; H. J. Noerling, Valatie; C. L. Nichols, Philmont; E. Niver, Hillsdale; S. V. Whitbeck, Hudson.
Delegate to State Society, S. J. Post, Philmont,

Alternate to State Society, L. J. Early, Hudson.
Dr. John Dardess of Chatham was elected to membership.

During the afternoon session two scientific papers were presented:

Dr. Arthur F. Holding of Albany gave a paper on the use of the bronchoscope in the treatment of pulmonary disease.

Dr. H. C. Galster described the Vienna Clinics, and related his experience while attending them.

L. VAN HOESEN, M.D., *Secretary.*

RENSSELAER COUNTY

The Medical Society of the County of Rensselaer held its regular monthly meeting in the Troy Health Center on Tuesday evening, October 11, with Dr. J. B. Burke, the president, in the chair, and Dr. Handron, secretary.

Dr. F. Sulzman, chairman of the committee on resolutions submitted a report on the death of Dr. T. A. Hull a pioneer of Roentgenology. Dr. Hull died at the Albany Hospital of coronary thrombosis at fifty-two years of age.

Dr. A. J. Hambrook, delegate to the State meeting, reported on the routine business of the society and its meritorious scientific program. He also reported on the meeting of the Third District Branch held at the Loomis Sanitarium (see the Journal of October 1, 1932, page 1137).

Dr. E. J. Hannan, representing the Troy health department of the public schools, stated that the department only renders first aid and physical diagnosis to scholars and does not give other treatments of any kind.

Dr. C. A. Hemstreet reported for the Public Relations committee that the committee had

met with representatives of the State Department of Health in regard to a study of the maternal mortality. He also recommended that the physicians consider the erroneous impression which seems to exist in regard to the service rendered patients admitted to hospitals as charity patients. Some of such patients were erroneously of the impression that the doctors serving them at such hospitals were paid employees.

Drs. Hemstreet, Green, Kivlin, Rainey, and Hambrook were appointed by the chair as a nominating committee for the 1933 officers.

The scientific program began with a paper by Dr. Charles R. Lewis on the subject "A Consideration of the Late Toxemias of Pregnancy."

The second paper was presented by Dr. S. Curtis on "Tumors of the Breast."

Dr. C. J. Handron read a paper on "Mitral Stenosis and Tuberculosis."

The meeting was well attended and the discussion showed keen interest.

WM. B. D. VAN AUKEN, M.D., *Reporter*.

DUTCHESS-PUTNAM COUNTY

A regular meeting of the Dutchess-Putnam Medical Society was held Wednesday, October 12, 1932, at Vassar Hospital, Poughkeepsie, N. Y. The meeting was called to order by the President, Dr. W. A. Krieger, at 8:40 P.M. Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, then presided.

The following physicians were elected to membership:

Dr. F. M. Hedgecock, Poughkeepsie.

Dr. A. A. Rosenberg, Poughkeepsie.

Dr. M. William Lynn, Hyde Park.

Dr. Neil C. Stone of Poughkeepsie was received on transfer from Westchester County.

Dr. J. W. Poucher offered a memorial for Dr. Harris L. Cookingham, who died on June 28, 1932, in his eighty-second year. Dr. Cookingham was a native of Dutchess County. He was graduated from Albany Medical College in 1871, and practiced Medicine in Red Hook, in the northern part of his home county, for a full half century. He was a splendid example of the family physician—doctor, counselor, and friend to three successive generations of the families in that section. He was not only active all his life as a medical practitioner throughout a large circle, but was prominent as a citizen both in the civic affairs of his home town and as an influential layman in his chosen church. He was engaged in his work until a very few days before his death.

Dr. Cookingham was married May 18, 1870.

to Miss Mary G. Nicks, who died a short time before her husband. Four children survive them, one of whom is our fellow member, Dr. Barton M. Cookingham of Rhinebeck.

The members of this society wish to express their highest appreciation of his long, successful career in the medical profession, their sincere admiration for his character, and their deepest regret for the friend and fellow member they have lost.

Dr. James E. Sadlier presented a memorial of Dr. John A. Card, a leading member of the Society, who died on June 28, 1932, aged 55 years. (See this Journal, July 15, 1932, pages 874, 880, and 882.)

Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, gave an address on the work of Dr. Card.

Dr. Frederic E. Sondern gave a paper on "Clinical Pathology and Diagnosis."

A letter from Commissioner Parran was read and referred to the Comitá Minorá.

Present: Drs. Heyd, Sondern, Krieger, Rogers, Marks, Peckham, Falliser, Storrs, Chapin, Appel, Breed, Harrington, Cronk, Herndon, Poucher, Deyo, Voorhees, Cavanaugh, Borst, Malvin, Rosenberg, von Tilling, Carpenter, Moffit, Rivnerberg, Green, Corbon, Lynn, White, Stoller, Warren, Sobel, Powell, Leonidoff, Toomey, McGrath, C. E. Lane, George Lane, C. A. Crispell, Thomson, Lewis, Gosse.

H. P. CARPENTER, M.D., *Secretary*.

THE DAILY PRESS

SPECIALISTS AS SEEN BY LAYMEN

Lay opinion of specialists is shown in the following editorial from the *New York Sun* of September 8, 1932:

"One exhaustive survey does not establish a fact, any more than one swallow makes a summer, but it is nevertheless encouraging to learn from the Committee on the Cost of Medical Care that data gathered by Dr. H. G. Weiskotten, dean of the Syracuse University College of Medicine, indicate that the tendency of medical school graduates to seek to become specialists has reached its zenith. As a matter of fact, Dr. Weiskotten's figures show merely that no greater proportion of the graduates of sixty-nine medical schools in 1925 limited their practice to a specialty than did the graduates of the same colleges in 1920. But because the tendency up to

1920 was altogether in the direction of an increasing concentration on specialization, Dr. Weiskotten believes that in the future fewer medical school graduates will deliberately plan to become specialists.

"This is encouraging to laymen, not because they distrust the specialist but because they trust the general practitioner. Physicians themselves would be the first to admit that division of labor in the field of medicine has been carried too far in the United States. The family doctor of old often had incomplete knowledge, but his wisdom was unsurpassed; the family doctor of today is not so common and familiar a figure, not so picturesque or eccentric, perhaps, but his knowledge is greater and his experience as enriching. It is good that the breed is not dying out."

CURED OF CANCER

The daily newspapers are giving considerable space to the American College of Surgeons, which is now meeting in St. Louis. The *New York Sun* of October 20 records the following encouraging evidence of the curability of cancer:

"More than 4,000 authenticated cases of cancer cure by surgery, radium treatment or both were reported by specialists to a session of the clinical congress of the American College of Surgeons here today.

"Added to the 1,263 cases already registered with the college and more than 3,000 others revealed by an incomplete survey of medical literature, these made a total of approximately 8,500 known cures in the United States and Canada.

"In each instance the patient treated was alive and well after five years, the period during which it is assumed the disease would reappear if not eradicated."

PARROT FEVER

The *New York Sun* of October 20th contains the following account of a new laboratory to study parrot fever:

"A parrot fever laboratory in southern California where science may explore mysteries of this disease is planned by the Public Health Service. Surgeon-General Hugh S. Cumming of the service, in announcing this today, said Secretary Mills had allotted \$10,000 to further research in psittacosis out of a treasury fund for preventing the spread of epidemic diseases.

"A very interesting evidence of the close intercommunication of continents, so that one part of the world is threatened by the disease in any other part," Dr. Cumming said in describing psittacosis from his personal acquaintance. His acquaintance began, he said, about three years ago, with a Sunday supplement story, which told of an opera troupe in the Argentine attacked by a strange disease, after a performance in which

birds were used as 'props,' Dr. Cumming said. 'I read it, with no particular sense of significance, and an Annapolis doctor read it the same way.

"But the very next day he noticed a sick parrot in the home of two patients whose ailment he had been unable to analyze exactly. He asked information of the health officer, and the Governor's office called me about it. I sent Dr. Armstrong over, and from that day on we've been finding out about—and fighting—psittacosis."

"The parrots brought into the Public Health Service laboratories here caused an epidemic in which eleven laboratory workers were stricken, one fatally. From its course, the scientists discovered that virus, not bacilli, as had been thought, was the cause of the disease; that parakeets as well as parrots were responsible; and that its best treatment was 'convalescent serum,' the injection into the blood vessels of the patient of serum from one recovered from the disease."

CHARITY, PRIVATE AND PUBLIC

Walter Lippman former editor of the *New York World*, writing in the *New York Herald Tribune* of October 20, discusses the field of public charity as distinguished from private giving Mr Lippman says

"In some cities sharp controversies have been brought on by those who insist that the starving have first call on the money available and that other kinds of social work must give way. In Denver, for example, there is an agitation demanding that the Y M C A, the Y. W C A, the Boy Scouts and Girl Scouts, and other organizations generally known by the depressing name of 'character-building' agencies, be excluded from participation in the funds of the Community Chest. The argument against them is in essence that the people have to be fed and that their characters can, for the time being, be left unattended.

"Those who have had long experience in the task of raising money for Community Chests say that, leaving aside all consideration of the value and necessity of normal social work, the fact is that the so called 'character-building' agencies are generally the pet philanthropies of well to do people. They believe in these agencies, and if they cannot support them through the general fund, they will support them outside the fund and give much less to it. The net result will be chaotic giving, in which some philanthropies will receive more than they absolutely need, and others for lack of powerful friends, will be grossly neglected. The expert in these matters concludes, therefore, that while the character builders ought properly be compelled to reduce their demands to the minimum of necessity, it would be a great mistake, from the point of view of raising the largest amount of money possible, to ignore them.

"However, it is not on this narrow basis that the problem ought to be considered. The social work of modern times is an attempt to deal with the physical, mental, and moral maladjustments of the young, the helpless, and the unknowing who are unprotected by their families and friends. The uprooting of human beings from the land, the concentration in cities, the breakdown of the authority of the family, of tradition and of moral conventions, the complexity and the novelty of modern life, and finally the economic insecurity of our industrial system have called into being the modern social work.

That in dealing with the consequences of modern life the social agencies are often be wildered, fussy, or pedantic in spirit and bureaucratic in method no one would deny. But their

usefulness is beyond all question, and will be denied by no one who takes the trouble to look into the matter. Life in the cities would be even more cruel and more destructive of human values than it is but for the social workers and their infinite gallantry and patience. They perform a function in modern society which is not a luxury but an absolute necessity.

"In times like these they are more necessary than ever. That applies most particularly to the 'character building' agencies. For the supreme evil of unemployment is that it is demoralizing. To provide food to keep men alive is an easy task in a country suffering from overabundance. The food exists, it can be had, it can be distributed, and if that were all there was to the problem of relief it would be a simple problem.

"But to keep men and women, young boys and girls from despair, from the hideous boredom of having nothing to do, from the crushing sense of not being wanted, of having no place in society and no work to do, of being a problem and not a human being—that is the real task of philanthropy in these long dreary days.

"The safeguarding of these human interests is the office of private philanthropy. Emergency relief of destitution caused by a general breakdown of industry is a public duty, and should not be allowed to destroy or seriously impair the work of private philanthropy. In so far as voluntary giving is not sufficient to take care of normal social work and of emergency relief as well, the burden of emergency relief must be shifted to the taxpayers."

Physicians will agree with Mr Lippman as he suggests that the burden of philanthropic service shall not be borne by private persons, as it would be by doctors treating the poor for nothing, but that it shall be borne by the community. Mr Lippman closes his article.

"The policy of depending upon private charity in the emergency has no foundation in principle. In so far as private gifts are adequate it is expedient not to raise the political question involved in a resort to public funds. But as the depression has continued and deepened, as the need has grown and private resources have diminished, the burden of emergency relief has in fact been shifted more and more from private donors to the taxpayers. It will undoubtedly have to be shifted much more this winter, and wherever the continuance of normal social work is threatened by the need for emergency relief, there the point has been reached where public money is unmistakably necessary."

OUR NEIGHBORS

GRADUATE COURSES IN NEW JERSEY

The supplement to the September issue of the *Journal of the Medical Society of New Jersey* contains the annual report of the Special Committee on Post-Graduate Medical Education which outlined the plan and courses given as follows:

"Professor R. H. Light, of the University Extension Division of Rutgers University, was designated by that Division to be in charge of Post-Graduate Medical Courses, and Dr. Harry H. Satchwell, a member of your State Society Committee, was appointed by the University as 'technical adviser' in Post-Graduate medical matters.

"By reason of the interest in and realization of the importance of this work, by the State Board of Regents last year, there was made available to the University Extension Division of Rutgers, for the prosecution of this year's work, sufficient funds to permit the University to reduce materially the fees for our courses. As a result of this, and of interest aroused by the study courses provided in previous years, your Committee has the gratification of reporting, for the instruction year just closed, the most successful year's work in its history in point of enrollment, number and variety of courses provided, and generally favorable reaction as expressed in the answers to questionnaires submitted by students. As a result of this policy of fee reduction, there has been, however, a small operating deficit, which has been generously absorbed by the University.

"Eight hundred and twenty students enrolled, for 25 classes, conducted in 13 centers, by 77 different teachers, 33 of whom came from New York, 1 from Newark, 1 from Boston and 42 from Philadelphia. Detailed lists of these courses, and of the faculty, and a financial statement are appended hereto."

The financial report of the courses in 1931-1932 is as follows:

"Expenses:

200 lectures @ \$50.00 each\$10,000.00
Travel Expenses of Lecturers...	1,071.47
Lantern and Rental Expenses...	301.00
Printing and Mimeographing....	490.41
Postage and Stationery.....	325.00
Telephone	295.00
Travel Expenses of University Extension Staff, Chargeable to Project	1,138.81
Salaries and Stenographic Services of University Extension Division Directly Chargeable to This Project	7,060.00
Proportionate Share of Office Overhead, etc., Not Including Administration, Which Is Carried on General Budget.....	795.00
	<hr/> \$21,476.69

"Income:

Twenty-five classes—	
675 Initial Enrollments	
@ \$15.00....	\$10,125.00
105 Duplicate Enrollments,	
@ 10.00....	1,050.00
40 Intern Enrollments	
@ 5.00....	200.00
	<hr/> \$11,375.00
820 Total Enrollments	10,101.69

"State Appropriation Allocated to Post-Graduate Medical Program 10,000.00

DEFICIT\$ 101.69"

STATE MEDICAL JOURNALS IN MAINE LIBRARY

The *Maine Medical Journal* of August pays its editorial compliments to the Journals of the Medical Societies of other States, in the following editorial:

"It seems to us a good idea to inform our readers that in the office of the *Maine Medical Journal* and in the library adjoining, a large number of medical journals from as many as thirty states in the Union are available at all times to medical men to read and think about. These magazines can be borrowed or read on the spot. More use, we insist upon it, should

be made of these exchanges. They keep us up-to-date as to American and foreign ideas and methods and thoughts on modern medical and surgical progress. We commend, for instance, regular reading of the *British Medical Journal*, and the journals of New York, Illinois, Indiana and other states are of great value. Thus in the June 18th number of *British Medical* we read a most promising paper on the abatement of the smoke nuisance existing all over the civilized world and a historical note on the obesity of

(Continued on page 1270 *adv. xvi*)

AN IMPROVED TREATMENT OF ARTHRITIS — A COMPARATIVE TEST

In a carefully controlled clinical investigation* of the comparative merits of Mono-Iodo-Cinchophen (Farastan), Cinchophen and Sodium Salicylate, the following results were obtained:

	FARASTAN Group I	Cinchophen Group II	Sodium Salicylate Group III
Pain:	Complete relief 90% Moderate relief 10%	No relief 90% Slight relief 10%	Complete relief 10% Marked relief 20% Moderate to slight relief 50% No relief 20%
Swelling:	Complete relief 75% Marked reduction 25%	No reduction 75% Slight reduction 25%	Complete reduction 10% Marked reduction 20% Moderate to slight reduction 45% No change 25%
Motion:	Complete restoration 80% Marked to moderate improvement 20%	Slight improvement 20% No improvement 80%	Complete restoration 10% Marked improvement 20% Moderate to slight 40% No improvement 30%

The author concludes that the marked relief of pain, reduction of swelling and restoration of motion is apparently due to the combined effect of cinchophen and iodine, made possible in the formula of Farastan.

good old Henry VIII. The annual address of the President of the Illinois State Medical Society, in their June number, is really noteworthy, with its frank statement of the causes of depression of the day and valuable remedies suggested. Then the *New York Journal* has every fortnight a number of small items of great value, for instance, in cases of malpractice, whilst an item on big fees in California, on page 768, demands attention from all practitioners. Last of all, at this time we notice a brief account in the *New England Medical Journal* of a small epidemic of tonsillitis arising from a single cow in Topsfield, Mass.

"Again we say, fellow members, widen your outlook by making closer acquaintance than of old with the files of the foreign and State medical journals on file in the office of our Medical Journal and the medical library adjoining.

"This office will gladly assist you in locating special articles and magazines."

The department of "Our Neighbors" of the *NEW YORK STATE JOURNAL OF MEDICINE* has quoted from the *Maine Journal* seven times during the past year, mostly records of the activities of the Maine Medical Association.

MAINE PUBLIC HEALTH ASSOCIATION

Lay public health activities in Maine are supervised and directed by a voluntary organization called the Maine Public Health Association, which was described in this *Journal* of June 1, 1930, page 676. This Association works in co-operation with the Maine Medical Association, as is shown by the publication of its annual report in the September issue of the *Maine Medical Journal*.

School health education has been conducted along the following lines:

Health habits promotions.

Six Point children (for conditions of grading see this *Journal* of November 1, 1930, page 1332).

Better teeth campaigns.

Contests in habits and health essays.

Public health nursing work was described as follows:

"Our staff nurses were carrying 32,774 individuals in our State for health supervision. These patients were distributed in 15 of our supervised services. Calls and demands for the nurses show a marked increase this year, many of them being for material relief or social welfare."

Tuberculosis work is described as follows:

"The only full-time worker is a registered nurse with Public Health Nursing Training. She

(Continued on page 1272—adv. xviii)

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

has also had special instruction in the use of the x-ray machine, in the technique of taking x-ray pictures, and the giving and reading of the Von Pirquet test. The clinic program is sponsored and directed by a committee of physicians who are specialists in diagnosing tuberculosis. These physicians approve of all policies governing the set-up of the program and also make a substantial contribution in other ways.

"During the period July, 1931, to July, 1932, the following is a summary of the work of the Clinic Nurse:

Von Pirquet skin tests given.....	3,472
Positive reactors to above tests.....	636
Patients x-rayed	715
Chest examinations	191
Active cases of pulmonary tuberculosis...	

"It is difficult to evaluate our accomplishments through the Health Educational Service. During the past year we have been sending Tuberculosis Abstracts to 18 physicians and 32 nurses monthly. We have circularized these physicians to see if they wished the abstracts to be continued. In order to increase our list for this coming year, we have written the various County Medical Societies, and our list now includes 70 physicians and 30 nurses.

"Each month the *Journal of the Outdoor Life* is sent to a selected group of tuberculosis patients."

Social Hygiene work was conducted as follows:

"The nurses of the Maine Public Health Association coöperated with the Social Hygiene Section by taking patients to the hospital for treatment, securing needed tests for diagnostic purposes, providing opportunities for programs on Social Hygiene for High Schools and Parent-Teacher Associations. This group of nurses and Miss Buck of the School Health Education Service arranged for some of the talks given by Dr. William Holt and Miss Herrick of the State Department of Health.

"Talks were given to high school groups in 16 cities and towns."

Dental clinics are described as follows:

"The Dental Clinics in both the urban and rural communities have nearly doubled during the past two years. These clinics meet the need of children whose parents have more than they can do to supply food, shelter and clothing. Dental Clinics reported by the Maine Public Health Association Nursing Services number 97, with an attendance of 706 school children, 2,120 examinations, 11,892 dental defects and 4,208 corrections."

Extensive work was also conducted by the sections on eye, ear, nose and throat, mental hygiene, orthopedics, cancer and heart.

More Effective . . . Safe! In Colds and Rheumatism

Because they combine the important factor of **safety** with powerful analgesic antifebrile effects, the salicylates continue to offer the classical treatment for rheumatic and arthritic conditions, as well as the physician's best weapon for fighting colds and influenza.

However, it is important to note that modern medical opinion stresses the need for combining alkalis with salicylates as assurance of optimum results and better tolerance.

Hence the introduction of

ALYCIN

• Let us send you a trial size package with our compliments for a clinical test.

Alycin combines the therapeutic advantages of Merrell's Natural Salicylates—increased tolerance even in massive dosage—with the correct proportion of a carefully balanced alkaline base to secure safe and effective alkalization.

Combined with the properties of easy tolerance, effectiveness and safety, Alycin offers the further important advantage of economy to the patient—two prescriptions in one product.

Maltcao Helps Retain Summer-Time VIGOR

During the winter months, when diets are heavier and vegetables less plentiful, Maltcao is a valuable adjunct to the daily diet. With a delicious chocolate taste, this scientific food drink supplies an abundance of calcium, iron, and phosphates in organic combination, just as nature produces them in grains and vegetables.

Maltcao is the only chocolate food drink, so far as is known, that contains these added organic salts.

3 oz. sample can to physicians on request.

THE MINISTER AND THE DOCTOR IN TEXAS

The Texas State Journal of Medicine for August contains the following editorial on the doctor as seen by the minister of the Gospel:

"We are pleased to present herewith a very excellent discussion of the physician from the standpoint of the ministry. We deem the item worth the space it occupies in the editorial section of the Journal, because of the importance of the cooperation of the doctor and the preacher in dealing with the sick, particularly the seriously sick.

"The author, the Reverend W. R. Hornburg, pastor of the Coggin Avenue Baptist Church at Brownwood, has prepared this little sermon for the good it might do, and with no thought of its publication in a medical journal. It follows:

"*'DO YOU WISH TO GET WELL?'* Certainly that is your wish. Every one wishes to enjoy good health. It is true that every one is liable to become ill. Disease germs are everywhere. We breathe them, eat them, drink them, "catch them" at every turn of life's way.

"Is it God's will that I should be sick? No. He has provided a remedy for every disease. Where may I find a remedy for my trouble? It is provided in Nature. Many men have made it their life business to find such remedies and apply them. They spend years and years in painstaking study seeking to know what others have learned, and exploring new realms of Nature, seeking out the cases of diseases and their remedies.

"We do not yet know all the causes for disease, nor have we yet discovered a remedy for every known disease. But be assured of the fact that there are men toiling day and night, leaving no stone unturned, that they might discover Nature's secrets of healing. These men are soldiers in the war on disease. Heroes, many of them, ready to lay down their lives that others might be saved. Money is being spent by the millions. Libraries are collected, laboratories are equipped, colleges and universities are built and endowed. Men of much learning and experience, specialists in their field, are brought together that they might teach others what they themselves have learned. Men and women of high intelligence must spend years in school and college equipping themselves that they might join in the war on disease.

"Your physician is a man of this type. He has spent years in patient preparation for his life's work. He has had competent teachers. All the best knowledge that has been accumulating through the centuries has been at his disposal. He has proved himself a master in his field and his services are now at your disposal. He knows

(Continued from page 1274—adv. xx)

your trouble better than you can possibly know yourself. Your case is not peculiar. He has seen many other cases just like it. If there is a remedy, he knows it. If there is none, he will tell you so. Of course, some people do not get well, but most people would get well and live to a ripe old age, if they would follow the advice of their physician. Your physician is your big reason for getting well. Believe in him. Trust him. Be frank with him and tell him all the facts. Follow his instruction, and, then, "Commit thy way unto the Lord. Trust in Him, and He will direct thy paths."

"It is true that the doctors cannot cure you. They do not claim to cure. Only Nature can heal. But your physician knows how to produce conditions that will enable Nature to do her work. Nature brought us into the world, and Nature must keep us fit while we are here. And it will be into the arms of Mother Nature that we will fall when we reach the end of life's way.

"Remember that the Laws of Nature are the Laws of God. Nature is God at work in plain sight. How beautiful to know that when Nature

speaks her healing, soothing word, it is the voice of God we hear.

"That in every breath of fresh air, in every life-giving ray of sunlight, it is God expressing His desire that we might be well and strong.

"There are four factors in your healing: God, who is the Author of your life, and who must sustain your life. Nature, who if God be our Father, is mother of us all. It is from her that we draw the healing streams for all our ills. Your physician, who knows Nature's laws and how they operate. He has discovered her secrets of healing and will use them for your benefit. Last of all, and most of all, yourself. Do you wish to get well? Then resolve to get well. Believe that you will get well. Every tender ministry that kindly hearts can devise have been provided for you. Lay your head trustingly upon Mother Nature's breast and feel the gentle inflow of her healing power. It is a long, hard climb to the City of Good Health, but we must resolve to make the climb. Remember that the very stars in their courses fight for you when you resolve to reach the heights. Your battle is half won when you say "I will."

"Now may we breathe this little prayer together?"

"Dear God and Father: I want to get well. My friends and loved ones want me to get well. My physicians and nurses want me to get well. I believe that Thou dost want me to get well. Thou dost control the forces of life. The laws of life are Thy laws. Wherein I have broken those laws, either wittingly or unwittingly, I ask Thy forgiveness.

"I commit my life to Thee. All of my dearest treasures I have received from Thee. I have sought, and others have sought for the remedy for my trouble. God bless those who minister to me, and guide me back to health and happiness. In Thy great love I trust.—Amen."

QUACK HEALTH LECTURES IN TEXAS

New York State is not a promising field for the quack health lecturer although now and then reputable organizations invite them unaware of their quackery. The July issue of the *Texas State Journal of Medicine* exposes such a quack in the following item quoted from the *Dallas News*:

"Use of the city hall auditorium will not be granted to Paul C. Bragg for a series of lectures scheduled for June 10, 11, 12, 13 and 14. Permit to use the auditorium was denied by City Manager John Edy and City Secretary Earl Goforth June 9, when William Collier, manager of the Better Business Bureau of Dallas, and Wilmer A. Rowan, special agent for the Texas State Board of Medical Examiners, brought to the attention of the city officials that a fraud order was issued by the United States Postoffice Department against Paul C. Bragg, the National Diet and Health Association of America, Bragg's Health Center, Bragg Laboratories and their agents and officers as such. This order, forbidding postmasters to pay any postal money orders drawn to the order of any of the individuals or concerns listed, and directed that postmasters return all letters and other mail matter addressed to these individuals or concerns to the senders with the word 'fraudulent' stamped thereon, was issued on December 30, 1930.

"Special Agent Rowan also presented evidence showing that this lecturer has recently concluded a series of lectures in Houston under the name of Paul Chappius, and that he had lectured in other cities, in some as Paul C. Bragg, and in others as Paul Chappius. It developed June 9, that advertisements announcing the proposed series of lectures to be given in the city hall auditorium had been accepted and published by Dallas newspapers before they became aware of the issuance of the postal fraud order against Bragg and his companies."

4 New Concentrated Vitamin Products

Vitamin A alone

Name Smaco Cantol Product No 305

Description: Cantol is a 3% solution of carotene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use

Taste: Entire absence of all fishy taste makes it acceptable to your patients.

Color: Deep red, due to carotene

Potency: Ten drops contain one thousand International Units of vitamin A

Dosage: Three to five drops daily for infants and young children. Five to ten drops daily for adults

Package: 15 c.c. dropper top, protectively-colored bottles, in special cartons to shield it from the light

Cost: Because of its high potency and the small doses required, it is an inexpensive source of vitamin A, in spite of the fact that it is the only product containing vitamin A alone

Indications: For conditions caused by vitamin A deficiency and cured or prevented by adequate vitamin A or carotene dosage

Vitamin D alone

Name. Smaco Concentrated Vitamin D Product No 515

Description. This product is Natural Vitamin D, being a highly potent extract of the antirachitic principle of cod liver oil

Taste: Palatable and free from objectionable taste

Color: Nearly colorless.

Potency: Ten drops are equal in vitamin D potency to three teaspoons of standard potent cod liver oil

Dosage. Average prophylactic dose, ten drops daily. Average curative dose, fifteen to thirty drops daily, depending on severity of case.

Package. 5 c.c. and 50 c.c. protectively colored bottles

Cost: Approximately the same as that current for equivalent vitamin D dosages of plain cod liver oil

Indications: For the prevention or cure of rickets and spasmophilia, and where ever vitamin D therapy is required, such as tetany and osteomalacia

Vitamins A and D together

Name Smaco Vitamins A and D Product No 525

Description Smaco Cantol and Smaco Concentrated Vitamin D are combined in this product, providing both vitamins A and D in concentrated form for therapeutic use

Taste Palatable and free from objectionable taste

Color Red, due to carotene

Potency Ten drops are equivalent to one thousand International Units of vitamin A plus the vitamin D potency of three teaspoons of standard potent cod liver oil

Dosage Ten drops or more daily, depending upon individual requirements

Package. 5 c.c. and 50 c.c. protectively colored bottles

Cost Approximately the same as current prices for equal dosages of other vitamin concentrates

Indications. Wherever vitamins A and D are required together in palatable form and small dosage

Smaco Cod Liver Oil fortified

Name *Smaco Cod Liver Oil (with Carotene and Concentrated Vitamin D) Product No 510

Description. A high grade cod liver oil fortified with vitamin A of vegetable origin (carotene) and natural vitamin D described in the second column

Taste. Although carotene is not a flavoring agent, nevertheless the addition of carotene noticeably improves the flavor

Color. Deep red, due to carotene it contains

Potency. One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod liver oil plus 1,000 International Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil

Dosage: One teaspoon daily for average individual needing vitamins A and D

Package. Four ounce protectively-colored bottles packaged in special cartons to shield from light

Cost. Approximately one-half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil

Indications Wherever a more palatable, concentrated cod liver oil is indicated. (Only one third as much is required as plain cod liver oil)

*Zucker natural vitamin D

New Vitamin Therapy Possible

Up to this time it has not been possible to prescribe vitamin A alone, as in cases where vitamin D is not required or is already supplied by sunshine, ultra violet light, viosterol etc. Smaco Cantol makes possible the administration of Primary Vitamin A in drop doses thus permitting the physician to regulate the dosage to meet individual requirements

Smaco Vitamin D is natural vitamin D. It is not an irradiated oil and not a cod liver oil concentrate, but rather a highly potent extract of the antirachitic principle of cod liver oil. It is produced for therapeutic use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University

It now becomes possible with these new Smaco concentrated vitamin products to prescribe vitamin A alone, vitamin D alone or vitamins A and D together in drop dosages and palatable form, thus permitting the physician to prescribe any desired potency of these vitamins and any desired combination

Smaco C
A and D
physicians

This Smaco Cantol has the same vitamin content of plain cod liver oil and only one third the dosage is required

Information and prices on crystalline Carotene (up to FIVE THOUSAND TIMES the vitamin A potency of cod liver oil) for research purposes furnished upon request

ence. The medical profession is a lifelong career which requires continuous study. You cannot be just to your clients and to yourself unless you make a real effort to keep yourself proficient in the profession. Next to proficiency is the spirit to serve well. There is nothing more convincing or more appealing to a patient than your willingness to respond to his call for your assistance at any time. Treat the rich and the poor, the ignorant and the educated equally. Endeavor always to make your visit at the same regular or appointed time, when your patient expects you. You will save him a great deal of fretting and perhaps prevent him from sending for your rival, who may be a quack, when the patient has grown tired of waiting for you. Punctuality is very important in our practice. Nothing can excuse the want of it, for the busiest people, as you all know, are the most punctual.

"As soon as you have established yourself, do not fail to seek membership in a medical society. We can serve our country better and promote medical practice and the medical profession more effectively if we are united in the form of an association. We can understand better, can help each other in a brotherly way, and can settle our petty differences in a friendly way if we are so united."

FEDERAL CHILDREN'S BUREAU LECTURES IN KENTUCKY

The October issue of the *Kentucky Medical Journal* contains the following editorial on a se-

ries of lectures on obstetrics, sponsored by the Children's Bureau, which is being criticized in the *Journal* of many State Medical Societies:

"We are happy to announce that during the spring and summer of 1933, the Federal Children's Bureau will again offer, through the Bureau of Maternal and Child Health, Dr. McCord's services. Postgraduate lecture courses, covering a period of four or five weeks, will be given. These courses will be sponsored by the Kentucky State Medical Association, the State Board of Health of Kentucky, and the local County Medical Societies. The Federal Children's Bureau will finance the courses; there will be no charge to any local Medical Society.

"At present there are several counties under consideration as suitable locations for the lectures. Announcement will be made later regarding dates and locations.

"Each course consists of five lectures, and usually a lecture is given every afternoon, from 2 to 5 o'clock, as follows:

"Monday: A general talk on the mechanism and management of normal labor, both being carried along together.

"Tuesday: The afternoon is opened with a talk on prenatal care, particularly as it concerns the prevention of the toxæmias of pregnancy.

"Wednesday: The prophylaxis and pathology of puerperal sepsis are discussed at length.

"Thursday: Forceps, version, occiput posterior positions and breech presentations.

"Friday: Abortions, accidental separation of the placenta and placenta previa are studied."

COLUMBIA UNIVERSITY NEW YORK POST-GRADUATE MEDICAL SCHOOL

offers an eight months' course in
OTO-LARYNGOLOGY

beginning February 1, 1933

Included in the course are: anatomy and physiology of the nose, throat and ear; embryology, histology, pathology and bacteriology of the nose, throat and ear (given by laboratory staff); dissection of the head and neck; nose, throat and ear operations (cadaver); daily clinics in a large out-patient department; bronchoscopy; etc. During the last few months the matriculate performs under supervision a number of the more common nose and throat operations in the out-patient department. Laryngology under the direction of Dr. Duncan Macpherson. Otology under the direction of Dr. Warren C. McFarland. For further information, address

THE DIRECTOR,

302 EAST 20th STREET, NEW YORK CITY

4 New Concentrated Vitamin Products

Vitamin A alone

Name Smaco Caritol Product No 305

Description Caritol is a 0.3% solution of carotene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use

Taste Entire absence of all fishy taste makes it acceptable to your patients

Color Deep red, due to carotene

Potency Ten drops contain one thousand International Units of vitamin A

Dosage Three to five drops daily for infants and young children. Five to ten drops daily for adults

Package 15 c.c. dropper top, protectively colored bottles in special cartons to shield it from the light

Cost Because of its high potency and the small doses required, it is an inexpensive source of vitamin A, in spite of the fact that it is the only product containing vitamin A alone

Indications For conditions caused by vitamin A deficiency and cured or prevented by adequate vitamin A or carotene dosage

Vitamin D alone

Name Smaco Concentrated Vitamin D Product No 315

Description This product is Natural Vitamin D, being a highly potent extract of the antirachitic principle of cod liver oil

Taste Palatable and free from objectionable taste

Color Nearly colorless

Potency Ten drops are equal in vitamin D potency to three teaspoons of standard potent cod liver oil

Dosage Average prophylactic dose, ten drops daily. Average curative dose, fifteen to thirty drops daily, depending on severity of case

Package 5 c.c. and 50 c.c. protectively colored bottles

Cost Approximately the same as that current for equivalent vitamin D dosages of plain cod liver oil

Indications For the prevention or cure of rickets and spasmophilia, and where ever vitamin D therapy is required, such as tetany and osteomalacia

Vitamins A and D together

Name Smaco Vitamins A and D Product No 325

Description Smaco Caritol and Smaco Concentrated Vitamin D are combined in this product, providing both vitamins A and D in concentrated form for therapeutic use

Taste Palatable and free from objectionable taste

Color Red, due to carotene

Potency Ten drops are equivalent to one thousand International Units of vitamin A plus the vitamin D potency of three teaspoons of standard potent cod liver oil

Dosage Ten drops or more daily, depending upon individual requirements

Package 5 c.c. and 50 c.c. protectively colored bottles

Cost Approximately the same as current prices for equal dosages of other vitamin concentrates

Indications Wherever vitamins A and D are required together in palatable form and small dosage

Smaco Cod Liver Oil fortified

Name *Smaco Cod Liver Oil (with Carotene and Concentrated Vitamin D) Product No 510

Description A high grade cod liver oil fortified with vitamin A of vegetable origin (carotene) and natural vitamin D described in the second column

Taste Although carotene is not a flavoring agent, nevertheless the addition of carotene noticeably improves the flavor

Color Deep red, due to carotene it contains

Potency One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod liver oil plus 1,000 International Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil

Dosage One teaspoon daily for average individual needing vitamins A and D

Package Four ounce protectively-colored bottles packaged in special cartons to shield from light

Cost Approximately one half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil

Indications Wherever a more palatable, concentrated cod liver oil is indicated (Only one third as much is required as plain cod liver oil)

New Vitamin Therapy Possible

Up to this time it has not been possible to prescribe vitamin A alone as in cases where vitamin D is not required or is already supplied by sunshine, ultra violet light, viosterol, etc. Smaco Caritol makes possible the administration of Primary Vitamin A in drop dosages thus permitting the physician to regulate the dosage to meet individual requirements

Smaco Vitamin D is natural vitamin D. It is not an irradiated oil and not a cod liver oil concentrate but rather a highly potent extract of the antirachitic principle of cod liver oil. It is produced for therapeutic use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University

It now becomes possible with these new Smaco concentrated vitamin products to prescribe vitamin A alone, vitamin D alone or vitamins A and D together in drop dosages and palatable form, thus permitting the physician to prescribe any desired potency of these vitamins and any desired combination

Smaco Caritol is a new product. This Smaco product is approximately one half as much as the same vitamin content of plain cod liver oil and only one third the dosage is required

Smaco Products like S M A are ethically advertised and carefully distributed through prescription pharmacies. No dosages are given in the list. Each package carries its statement. Use as prescribed by your physician

Information and prices on crystalline Smaco (up to FIFTY THOUSAND TIMES the vitamin A potency of cod liver oil) for research purposes furnished upon request

CANCER COMMITTEE IN MISSOURI

The Journal of the Missouri State Medical Association for July contains the following report of the Cancer Committee, that was appointed at the 1931 State Meeting:

"In order to comply with the first duty as outlined in the By-Laws, namely, to investigate the facilities provided for the cancer sufferer in the State of Missouri, a letter and questionnaire were sent to the eighty-eight county medical society secretaries. This questionnaire stated the number of patients who died of cancer within the jurisdiction of the county society during the year 1930 (these figures obtained through the Secre-

tary of the State Board of Health); and then proceeded to ask the following questions: (1) the opinion of the secretary of the facilities for the handling of cancer patients in his county; (2) in what proportion of cancer cases was the diagnosis made within one year after onset and (3) whether or not the following facilities are available in his county: tumor tissue diagnosis, radium treatment, radical cancer surgery, x-ray diagnosis, x-ray therapy and hospitalization of cancer cases.

"These questionnaires were sent out in April. To date sixty-six replies have been received. These replies have been analyzed and tabulated and a map prepared. Roughly stated it made be said that sixteen out of the one hundred and fifteen counties of the State have good facilities for the care of cancer patients; five have partial facilities, and forty-five have poor or in most cases no facilities. No reply was obtained from the questionnaires sent to the remaining twenty-two county medical society secretaries.

"General discussion of the question of cancer control in the State of Missouri at the meeting of the Cancer Committee in Columbia led to the following program to be recommended to the State Medical Association:

"1. The most crying need in the opinion of your Committee is to provide for all doctors in the State of Missouri competent facilities for the free diagnosis of tumor tissue with the establishment of a central laboratory to care for this work. The Committee feels that the State University School of Medicine situated at Columbia is the logical place for this laboratory, provided funds can be obtained for this special work either from the State Medical Association, private sources, or preferably and most logically a special appropriation by legislature for this specific work.

"2. A general educational program should be undertaken in cooperation with the American Society for the Control of Cancer. This program can be carried out by enlisting a number of capable men, members of the State Medical Association, to appear at County Medical Meetings and District Councilor meetings to give Cancer Clinics and to address lay meetings.

"3. Through the cooperation of the editor of the *Missouri State Medical Journal*, monthly articles of the unsigned editorial type devoted to some phase of the cancer problem are to be published in the *Missouri State Medical Journal*. These articles are in the course of preparation.

"4. Further educational work could be instituted by staging an exhibit at the Missouri State Fair under the auspices of the State Medical Association and in cooperation with the Secretary of the State Board of Health. Such an exhibit can be of a popular nature to educate the laity to the importance of the recognition of possible early symptoms and signs which may mean cancer."

MEDICAL STANDARDS IN THE PHILIPPINE ISLANDS

The August issue of the Journal of the Philippine Islands Medical Association contains an address by Dr E D Aguilar, President of the Association, on July 9, 1932, to the Board of Medical Examiners and newly admitted members of the medical profession. The following advice applies equally well to newly licensed doctors in New York State.

"In entering upon a field of endeavor like ours, the first question that naturally arises is: How shall the young physician start his practice? My counsel is this: If you can afford it and opportunity offers, try to obtain practical experience by associating with an elder brother in the profession who has already acquired a reputation and unquestionable experience either in hospitals or clinics. By so doing you can minimize the possibility of failure and increase your chance for success. If, owing to unfavorable circumstances, you cannot follow this course then there is no other way but to start private practice by yourself. However, before starting you should formulate a plan. I should advise you to establish yourself in a community in which you can practice most advantageously, not only from the standpoint of the profession, but also in accordance with the needs of the country. The tendency to start in a community in which there is already an oversupply of physicians is very detrimental to the profession as well as to our country. At present there is a markedly uneven distribution of physicians in the country. The result is that in some places people cannot help but resort to quackeries, and in others physicians must resort to unethical practices and procedures in order to earn a living. This is one of the main problems confronting our profession and our country as a whole.

One effective way, although a rather difficult one, of reducing to the minimum the practice of quackery is for us to compete with the quacks. The only way to do this is to demonstrate by actual deeds our superiority over them and our sincerity in serving the people. The present problem of unethical practice is one that can be solved gradually by not crowding in one place. You should all make the effort to establish yourselves in places in which there is very little or practically no competition among medical practitioners.

Recourse to unethical practices to take advantage of a colleague or of the ignorance of the people has no legitimate place in our profession. Competition in medical practice should exist only in the form of superiority, by deeds and not by words and signs.

This brings me to another piece of advice that I wish to offer you. For a physician to succeed in his vocation, he should continue his studies and he should not, after graduation, fail to keep pace with the progress of the medical sci-

ADVERTISEMENTS IN GEORGIA JOURNAL

The September Journal of the Medical Association of Georgia contains a report of the Publication Committee given at the annual meeting of the State Association on May 18, 1932, as follows:

"The Chairman stated that the purpose of the meeting was to consider complaints from some oculists who objected to the advertising by opticians in the Journal.

"The objection that is being made to the optometrists is due to the fact that they are advertising in a manner that is misleading to the public, and to the physician, and that is unfair competition to the oculists. It is particularly misleading to the public when they see an advertisement in a medical journal, apparently with the approval of the State Association.

"We have no strictly dispensing opticians. All of them compete with the oculist, and the physicians out in the smaller towns in many instances do not know the difference between a doctor of optometry and an oculist. We have discussed the question of appointing a committee and feel that it would be dangerous to try to distinguish between them for fear of laying ourselves liable in this way. All the advertisements are more or less objectionable. All of them in Atlanta are doing refracting or other work in competition with the oculists. The consensus of the Club is that it is best not to accept such advertisements for the Journal of the Medical Association of Georgia.

"The out-of-town doctors do not distinguish between an optometrist, an optician and a medical oculist. It is very confusing for the average layman or physician when these men are listed as doctors.

"If we refuse to accept these advertisements it will take away part of the income from the Journal. Do you think the wholesale optical houses would advertise with the Journal if these ads were cut out? The advertisements from the oculists have been in existence since 1911 and take care of

all the mailing expense for the Journal. I am sure they could have no legal course against you if you selected which should be used and which should not. If we had a low-class drug store I do not think we should allow its advertisements in the Journal. If you appoint a committee and it will give us the names of two or three that are not objectionable we will be glad to run their advertisements."

The Committee named seven optical firms whose advertisements would be acceptable. The September Journal carries four optical advertisers, all of which are on the accepted list.

GROUP INSURANCE IN NEBRASKA

The October issue of the *Nebraska State Medical Journal* has the following record regarding group insurance:

"A letter from Secretary Adams of the Nebraska State Medical Association states that 'we have just been notified by the United States Fidelity and Guaranty Company that on October 1st, 1932, they will cancel the group policy under which they have insured our members against malpractice suits. They have been threatening this for the last two years and your Insurance Committee with Dr. Selby as chairman has done everything possible in its power to prevent it. However, due to the fact that the Company has lost money ever since it issued this policy they have decided to discontinue it. This will mean that every doctor will have to look to his liability insurance as an individual and deal with the Company from that point of view.

"Any member of the Association who is insured under our group policy and his policy extends beyond October 31st, 1932, will have the remainder of his premiums returned to him."

"There have always been some doubts of the wisdom of the plan and the members of the profession as individuals did not in sufficient numbers take to it; hence its failure."

blood cells numbered 6,150,000, hemoglobin 130%. White blood cells were 13,400, with 76% polymorphonuclears, 22% small mononuclears and 2% large mononuclears. Blood pressure was 120/70. The urine had a faint trace of sugar by Benedict's. The blood Wassermann was negative and all the blood chemistry readings were normal.

Opinion: (1) Chronic pulmonary tuberculosis with thickened pleura; (2) chronically diseased tonsils.

He remained in the hospital only two days and tonsillectomy was advised against because it was believed he had an active pulmonary tuberculosis. During his stay in the hospital his temperature was 98.6° in the morning and 99.2° and 99.4° on to occasions in the afternoon. He was discharged two days after admission with the final opinion of chronic pulmonary tuberculosis.

After his discharge from the hospital the patient returned to work for a few days, during which time he had no particular complaints. X-rays were taken by an outside physician who told him that he had some pulmonary pathology but did not reveal to him the exact nature of it.

A little less than a month after his discharge he was readmitted complaining of cough with expectoration. The physical signs were the same as those on his previous admission, namely, dullness over the right upper lobe with suppressed breath sounds and numerous medium sized rales. At this time slight curvature of the nails was noted. Eighteen sputa were examined and no tubercle organisms were found. Careful examination for fungi of the sputum was then advised. One month later the bacteriology department reported the growth of actinomyces grown anaerobically, after two weeks incubation. During his stay in the hospital the patient ran a temperature of 98° to 102.4°, which was invariably highest in the afternoon. The pulse was moderately increased, from 80 to 110, showing a definite relation to the temperature curve. The patient continued to complain of cough with whitish expectoration and on one occasion his sputum was blood tinged. At the time of discharge a definite diagnosis of pulmonary actinomycosis was made. Unfortunately neither the original x-ray plates nor the reports of them are obtainable, so we are not able to include them in our case summary.

CASE 2—M. F., male, age 30, married, Hindu. Admitted to the hospital January 2, 1930.

Chief Complaint: Cough with expectoration, pain in the left side of the chest, fever, weakness, insomnia.

Family History: Negative.

Past History: Denies all kinds of infectious diseases.

Present Illness: Began about three months

prior to admission, at which time he began to cough and expectorate whitish sputum. Shortly after this he noticed that the sputum was bloody. Two weeks previous to admission he was taken suddenly ill with sharp pain in his left chest, aggravated by deep breathing. Within a few hours he had a severe chill. He went to bed and thought he had some fever. Since the onset weakness has been progressive and he has been unable to sleep. Because the patient was a Hindu and spoke practically no English further details of his history are not obtained.

Physical Examination: Temperature, 101°; pulse, 80; respiration, 40. Except for slightly irregular pupils the physical findings of importance were localized in the chest and the following is quoted verbatim from his examination at the time of his entrance. "Thorax small and symmetrical, the entire left side lags as compared to the right. A dull note is percussed over the left clavicle extending to the fourth interspace, below which it is resonant. The left axilla is resonant throughout. The entire right front and axilla seem a little hyper-resonant. Fremitus is slightly increased over both uppers, but more over the left. Broncho-vesicular breath sounds are heard over the right upper, suppressed broncho-vesicular breath sounds over the left upper with showers of fine crepitant and sub-crepitant rales. Posteriorly the left lung is dull from apex to base. Fremitus is slightly increased over the entire side. The right side is resonant throughout. Harsh broncho-vesicular breath sounds are heard over both apices, tubular breath sounds over the left lower with a few crepitant rales. Vesicular breath sounds over the right lower and no rales are heard. Bronchophony is heard over the entire left side." The heart, abdomen, and extremities are all negative.

Opinion: Resolving pneumonia, left side; tuberculosis, apical, bilateral.

Course of Illness: During the first month in the hospital the patient's symptoms and physical findings remained about the same. He continued to cough and expectorate bloody sputum with gradually increasing weakness. Pain in the left chest was the one thing of which the patient complained most bitterly; he also had marked night sweats and an occasional chill. The temperature was intermittent with daily variations from 99° to 103°; the afternoon temperature being always higher than the morning the pulse ranged from 72 to 130, averaging about 90. Respirations were from 20 to 30 per minute. Blood pressure was constantly low with an average systolic of 70 mm. and a diastolic of 30 mm. One month after admission a mass the size of a walnut appeared over the left third intercostal space in the mid-clavicular line. It was hard and tender but showed no redness or fluctuation. It was thought to be an empyema necessitatis. The mass

was aspirated on three occasions but at no time was material of any nature withdrawn. It was then suspected that he might have actinomycosis and the sputum was examined for fungi. These were not found on three occasions. Thirty-nine days after admission he developed a frank hemoptysis, following which he went into shock and died the next day.

Summary of the Laboratory Findings and Special Study: Repeated x-ray plates were made and the findings were suggestive of a massive collapse of the left upper lobe, thought to be due to a plugged bronchus and showing complete non-aeration from the apex to the fourth rib. These findings were constant in four studies of fluoroscopic plates taken over a period of forty days. The red blood cells at the time of admission were 4,500,000; hemoglobin, 80%. A secondary anemia developed and the red cells dropped to 3,000,000 and the hemoglobin to 45%. The white cells showed a fairly constant leucocytosis of about 14,000, the highest count being 16,800. The polymorphonuclear leucocytes were increased from 78% to 86%. The urine was negative, on several examinations, for any abnormal findings. The stool was negative for parasites and blood. Twenty-eight specimens of sputa were examined and no tubercle organisms found. Culture of the sputum showed a growth of staphylococcus aureus, hemolytic streptococcus, and pneumococcus of undetermined type. Several blood cultures were sterile. Wassermann reaction was negative. The patient died the 11th of February, 1930, forty days after admission and came to autopsy, the results of which are as follows:

Autopsy, February 12, 1930.

The body is that of a male East Indian, about 40 years old. Muscularly well developed but poorly nourished. The only external abnormality of note is a swelling in the region of the left breast. On reflection of the soft tissues of the thoracic wall this swelling is found to be due to a deep abscess formed by extension of a suppurative process through the intercostal muscles and fascia. About 10 c.c. of a thick purulent exudate are found under the breast and pectoral muscles and in the underlying intercostal muscles.

On removal of the sternum the mediastinal structures are found displaced somewhat to the left. The right lung is markedly emphysematous throughout but otherwise grossly normal. The left lung is firmly adherent over all its surfaces to a dense thick layer of scar tissue which obliterates the pleural cavity entirely. This layer varies from .5 cm. to 2.5 cm. in thickness. The thickest portion is over the anterior margin of the upper lobe and in this region the tissue is riddled with small yellowish areas of necrosis from which a purulent material can be expressed. These abscesses are continuous with those de-

scribed above in the intercostal and submammary tissues. The adjacent pericardium is also densely adherent in this region and several of these abscesses are present on the inner surfaces of the parietal layer of the pericardium. The left lung is markedly reduced in size, very firm in consistency, and its lobes fused. Multiple section reveals an advanced indurative pneumonia involving almost the entire lung (except for a small area at the lower medial aspect and the apex of the lower lobe). The two lobes are separated by a band of the same dense connective tissue encountered over the outer surfaces. The parenchyma of the lung in the consolidated areas is mottled by alternate areas of anthracosis and dense strands of gray-white connective tissue. The walls of the larger bronchi are thickened and many of them contain necrotic exudate. The smaller bronchi show marked bronchiectasis. Occasional bronchiectatic cavities are found completely filled with necrotic exudate and lined by a ragged layer of necrotic tissue. Yellowish abscesses noted in the pleura extend deeply into the lung tissue of the anterior margin of the upper lobe.

The pericardium, in addition to the involvement noted above, contains a smaller amount of fluid and both layers are partly covered by a very recent thin fibrinous deposit.

The heart is of normal size and shape. The myocardium is soft, particularly near the apex of the left ventricle where the deep reddish-brown color of the muscle wall is clearly seen through the epicardium. On incision the left ventricle is found somewhat dilated. The right ventricle shows a marked eccentric hypertrophy. Between the columnæ carneæ at the apex of the left ventricle are found globular grayish-white masses of thrombi. In this region the left ventricular musculature shows an intense hemorrhagic mottling. Occasional thrombosed vessels are also noted. The remaining myocardium is paler than normal. Small compact thrombi are found in both auricular appendages. All of the valves are normal. The aorta, except for early atherosclerosis at the base, is normal.

The spleen is normal in size and shape, slightly firmer than normal and congested.

The liver is of normal size and shape. On surface inspection and cut section are seen the markings of chronic passive congestion.

The kidneys are of normal size and shape. The capsule strips with ease. The surfaces are smooth but congested. On section, except for a moderate degree of cloudy swelling and chronic passive congestion, the renal tissue appears normal.

The adrenals, pancreas, stomach, and remaining abdominal organs are grossly normal.

Smears made from purulent material in the thickened pleural layer show occasional gram-

positive filamentous organs suggesting actinomycosis. Cultures confirm these findings.

Anatomical Diagnosis.

1. Actinomycosis, lung.
2. Pneumonia, interstitial, chronic actinomycosis, left lung.
3. Pleurisy, adhesive, chronic actinomycosis.
4. Empyema necessitatis.
5. Pericarditis, acute fibrinous.
6. Myocarditis, acute suppurative.
7. Thrombosis, intracardiac, septic.
8. Emphysema, pulmonary, alveolar, compensatory—right lung.

Although it is not our intention in a paper of this type to deal too scientifically with the bacteriology and cultural characteristics of the actinomycosis organism, perhaps a brief summary of some of its gross points may be of value. There has been considerable discussion and confusion in the classification and nomenclature in the trichomycetes of which the actinomyces is a subdivision. But it is generally believed that it belongs to the group of true moulds and not bacteria. Inasmuch as the ray fungus is a slow growing anaerobe and the pus from actinomycotic abscesses is often contaminated with other organisms, it is at times difficult to separate this mould from secondary invaders. And it is because of this that it is not easy to culture the fungus from the sputum. Wright* suggests, if the material to be examined is heavily contaminated with secondary invaders, that it be placed on the side of a test tube and after a period of two or three weeks most of the contaminating bacteria will have died, but the actinomycotic granules will remain viable. Great resistance to drying is shown by actinomyces and viability has been reported after a year of drying. Not all the individuals who harbor the actinomyces develop the disease and there is an individual susceptibility which plays a large part. Wright experimentally inoculated 80 animals, of which only 30 developed the lesions. Tonsils and carious teeth are considered as starting points of actinomycotic lesions in man. It is believed that direct transmission from animals to man is not common. Many cases occur in individuals who have never been engaged in handling grains or been in contact with pre-existing cases. The grain on which actinomyces is most commonly found is barley. Many observers believe that the ray fungus is a frequent inhabitant of the mouth and only invades the tissues when trauma makes it possible.

Pathologically, the organism causes a necrosis of tissue with marked leucocytic reaction with liquefaction and pus formation; and surrounding this is a dense fibrous tissue.

Infection of the lungs takes place by aspira-

tion and is probably disseminated along the lymphatics and by embolization to other organs. The disease is more common in males than females the ration being 4:1. It may occur at any age but most cases reported are in individuals from 20 to 30.

The train of symptoms most commonly present consists of cough with expectoration of a mucoid and bloody sputum; loss of weight; night sweats; weakness; emaciation, and chest pain. This severe, persistent, boring type of pain is often the patient's dominating symptom and is emphasized by all writers as being most significant. There is usually a slight secondary anemia, moderate leucocytosis of from 10,000 to 15,000 with an increase in polymorphonuclear leucocytes to about 80%. The temperature is septic with an associated rise in pulse rate.

The physical findings depend upon the underlying pathology. Christison* and Warwick have described four types of lesions in the lungs, namely, (1) bronchitic, in which the infection is confined to the bronchi; (2) pneumonic, in which the infection spreads from the bronchi and alveoli and gradually coalesces to form large abscesses; (3) pleuro-pneumonic, in which the abscess has grown large and burrows to the pleural cavity; (4) metastatic nodules, which they believe are carried to the blood streams. These authors believe the first three of these types are different stages of the same process. It is therefore to be seen that the physical findings may vary greatly from a simple bronchitis to an area of consolidation, or may be those of cavity formation.

Although the x-ray findings are of unquestionable value the benefits derived from them will often depend upon the type of pathology. The roentgenologist perhaps cannot say definitely that the case is one of actinomycosis but an experienced x-ray man will be able to say that the case is not one of tuberculosis, which disease is undoubtedly the one that will cause most confusion in attempting to establish a differential diagnosis, not only from an x-ray standpoint but also clinically. The x-ray findings in tuberculosis are reasonably constant and present to the roentgenologist a fairly definite picture and any slight deviation from these findings is usually enough to put him on his guard and make him suspect that there is some uncommon condition present. Christison and Warwick have drawn up the following table as an aid in differentiating these two conditions.

<i>Actinomycosis</i>	<i>Tuberculosis</i>
1—Lower lobes usually involved.	1—Upper lobes usually involved.
2—Lymph nodes never involved.	2—Lymph nodes involved.
3—Pain common and severe.	3—Pain rare.

* Wright, J.: Public Health Report, 1911, xxvi, 319.

* Christison, J., and Warwick, M.: Actinomycosis of lungs and suprarenals, *J. A. M. A.*, 89:1043, Sept. 24, 1927.

Actinomycosis

- 4—Cavity formation less common
- 5—Spreads by continuity.
- 6—Frequent sinus in chest wall
- 7—Abscess formation frequent
- 8—Often spreads through diaphragm
- 9—Fungus in sputum

Tuberculosis

- 4—Cavity formation frequent
- 5—Metastasis by blood
- 6—No sinuses
- 7—Abscess formation less frequent
- 8—Rarely spreads through diaphragm
- 9—Tubercle bacilli in sputum

Unfortunately the diagnosis of pulmonary actinomycosis is not usually made until the disease is well advanced. The outlook, therefore, from a therapeutic standpoint, is not particularly hopeful. Iodide, in the form of potassium iodide solution, or tincture of iodine, has been considered specific for years. Epstein* and Schoenholz believes that its value is questionable and they have found that 2% of potassium iodide in culture media will not inhibit the growth of this fungus. They believe that the benefit derived from iodine administration is obtained by absorption of inflammatory tissue. Specific vaccine therapy has been highly recommended. Non-specific protein therapy has been suggested, but is probably of little value. X-ray and radium offer little, if any, hope. Surgery of the thorax seems to be the most beneficial procedure, and incision, or curetting with cauterization, have been curative. Ordinary mouth care for apical abscesses and pyorrhea are important prophylactic measures.

* Epstein, N. & Schoenholz, P. Actinomycosis: report of cases. Calif. & Western Med. 30:395, June, 1929.

Summary Pulmonary actinomycosis is a rare disease, but occurs often enough in any large, active, medical service to force clinicians to be at least on the alert for its occurrence. Given a case with the clinical syndrome presented above, namely, cough with expectoration, frequently bloody, night sweats, loss of weight and strength, and chest pain, associated with indefinite physical findings of a bronchitis or partial consolidation or cavity formation, and further associated with an intermittent fever, a moderate increase in leucocytes, and the persistent repeated absences of tubercle bacilli in the sputum, then the possibility of pulmonary actinomycosis should be borne in mind. Add to this x-ray findings which are not definitely those of tuberculosis and the possibility of pulmonary actinomycosis is even more strongly suspected.

It must also be remembered that it is often necessary to make repeated examinations for ray fungus in the sputum before the organism is obtained. We believe that if the clinician bears all these facts in mind a diagnosis of this condition will be made more often.

Conclusions (1) Pulmonary actinomycosis may be diagnosed. (2) Persistent severe pain in the chest, associated with a train of symptoms and physical signs described above, makes a clinical picture which is reasonably definite. (3) A constant moderate leucocytosis associated with an increase in polymorphonuclear leucocytes is among the important means of differentiating this condition from pulmonary tuberculosis with which it is most apt to be confused.

RECENT ADVANCES IN KNOWLEDGE OF THE FUNCTION OF THE OVARY*

By RAPHAEL KURZROK, Ph D, M D, NEW YORK, N. Y.

From the Departments of Obstetrics and Gynecology and Biological Chemistry, and Sloane Hospital College of Physicians and Surgeons, Columbia University. This Research was aided by a fund from The Chemical Foundation. Read before the New York Academy of Medicine, Section of Medicine, May 17, 1932.

THERE are three hormones derived from the ovary, one from the follicular apparatus and two from the corpus luteum. Unfortunately the former is known by many different names, such as, the female sex hormone, theelin, folliculin, estrin, progynon, feminin, sistomensin and many others. This has led to much unnecessary confusion. The name theelin is beginning to be accepted as the name for this hormone. The hormones from the corpus luteum are known as lutein or progesterin, and relaxin.

The names intimately bound up with these hormones are, Schickel, L. Adler, Iscovesco, Fellner, Herrmann, Robert Frank, Stockard, Papanicolaou, Allen, Doisy, Butenandt, Loewy, Parkes, Corner, Hisaw and many others. To them must be added that group of scientists whose work on the anterior pituitary has furthered our knowledge of the ovary, as Philip

Smith, Engel, Zondek, Aschheim, Evans, Long and Allen.

The progress in the development of ovarian hormone was slow because there was no definite test for the qualitative determination of ovarian hormone. Such methods of detecting the hormone, as its effect on blood vessels, hemostasis, and its ability to contract uterine musculature, gave erroneous results, for we now know that the crystalline hormone has no such effects. Furthermore, the methods used in the extraction of the hormone were those used for the extraction of the active principles of other ductless glands. That again is wrong, for every gland has a distinct chemistry, and every active principle a different method of isolation. Clinical studies alone are not sufficient to isolate and identify a hormone, but on the other hand, I wholly disagree with many of our theorists who discredit clinical

observations. Only by the cooperation of the pure scientist and the clinician are the best results to be obtained in this field.

An important step forward was made by L. Adler¹ in 1912, who studied the effect of ovarian extracts upon the genital organs of animals. He made watery extracts of the ovary and corpus luteum and injected them into infantile guinea pigs and produced effects upon the uterus which resembled estrus. Aschner² obtained somewhat similar effects with the use of placental extracts.

Iscovesco³ in 1912, and Fellner⁴ in 1913, independently of one another, realized that the growth of the uterus could serve as a test for the presence of theelin. Fellner obtained lipoidal extracts from the ovary and placenta, which produced uterine growth as well as changes in the endometrium that greatly resembled pregnancy, and also growth of the mammary glands (but never secretion of milk). These studies were an important step forward, in that the infantile uterus as well as the uterus after castration served as a test for theelin, and secondly, that the hormone could be extracted by lipoidal solvents.

Herrmann⁵ in 1913 reported that a lipoidal extract of the corpus luteum and of the placenta when injected into an infantile rabbit produced hyperemia of the genital tract, swelling and secretion of the endometrium, and secretion from the breasts.

Unfortunately, the growth of the uterus alone is not a good index for the presence of ovarian hormone, because there occur distinct seasonal variations in its size, and secondly, injections of proteins and biogenous amines, that is non-specific substances which are carried along by the extracting process, also produce uterine growth.

The specific effect of the ovary can be obtained by an extract of the ovary and also by homoio-plastic ovarian transplants. When an ovary is transplanted it is hoped that the implant will remain alive and continue to secrete its specific hormone. Unfortunately, it is only a rare implant that does this, while the others either become fibrotic or are soon absorbed. It is during this period of absorption that the hormone from the implant is absorbed by the host. Repeated implants would thus be of value, but are not feasible clinically.

The next method for the testing for presence of theelin was the result of the studies of a group of American workers, Stockard and Papanicolaou (1917),⁶ and Evans and Long,⁷ and Allen in 1922. These investigators found that, synchronously with the cyclical changes that take place in the ovaries, there occurs a cyclical change in the uterus and vagina, and, what is most characteristic, the vaginal secretions partake of this change. By studying the vaginal secretions of the rodents it was possible to determine the different phases of the estrus or ovarian cycle. It is

not necessary to operate on the animal or to sacrifice it, but a vaginal smear enables one to tell immediately in what phase of the cycle the animal is. Castrated animals have no cycle. The estrus cycle in an animal is represented by four phases:

1. Dioestrus (interval) = mucous, leucocytes, epithelial cells.
 2. Proestrus = epithelial cells.
 3. Oestrus = cornified cells.
 4. Metoestrus = leucocytes, epithelial cells, cornified cells.
- Castrate = mucous, leucocytes, epithelial cells.

Castrated animals never show cornified cells. If one administers to a castrated animal ovarian extract or female sex hormone then this exogenous hormone produces in that animal an estrus cycle, as manifested by the appearance of cornified cells in the vaginal smear. The least amount of hormone that will produce an estrus cycle in an adult castrated female rat is known as the rat unit. Similarly the mouse unit. One rat unit equals eight to twelve mouse units. The appearance of cornified cells is specific for theelin. Body fluids (except urine), biogenous amines, non-specific proteins or glands of internal secretion, other than the ovary and placenta, never produce cornified epithelium.

By means of ovarian transplants, using the different structures of the ovary, theelin may be localized as follows: It is present in the follicular apparatus (follicle wall and follicular fluid) as well as in the corpus luteum, although the corpus luteum after menstruation contains little or no hormone. There is thus a constant production of theelin in the woman, first, in the follicle, then in the corpus luteum and this can be readily determined by an examination of the urine or the blood. The normal woman is constantly under the sway of this hormone—hence the name suggested by Frank—female sex hormone—is very appropriate.

Theelin is dissolved in the lipoids of the ovary, although the demonstration of lipoids histochemically does not necessarily imply the presence of female sex hormone. For example: The corpus luteum of pregnancy contains very little lipoids, but a considerable quantity of theelin. The corpus luteum after menstruation contains a great deal of lipoids but very little hormone.

With the new test for theelin it is now possible to study the effect of x-ray not only upon the anatomical but also upon the functional changes in the ovary. We are especially indebted to Parkes of London for the study on the mouse. If the mouse is given 300 to 400 R the entire follicular apparatus is destroyed, but in spite of that there is a constant rhythmic recurrence of the estrus cycle for several weeks or months, thus showing a constant rhythmical production of

ovarian hormone. There is therefore in this animal a notable difference between operative and α -ray castration, for in the former there is an immediate loss of estrus and theelin.

The effect of α -ray stimulation is as follows: The administration of 1/10 of a castration dose in immature animals produce slight anatomical stimulation of the follicles. Larger doses stimulate the follicles up to the stage of rupture, but there is never any theelin in them. There is premature follicle growth but not premature hormone production. The effect of the α -ray upon human ovary as far as it pertains to theelin has as yet not been completely studied.

THE ISOLATION OF THEELIN

The chief sources for theelin are follicular fluid, corpora lutea, placenta (500 r.u. in a full term placenta), the urine of pregnancy (500-1000 r.u. per liter, horse 10,000 r.u. per liter). Beginning with the second month of pregnancy there is a constant increase of theelin in the urine, and then it completely disappears by the tenth day post-partum. The cause for this large production is not known. Its source is the placenta, for the production of theelin continues when the ovaries are removed. Normally in the non-gravid state a woman excretes in the urine 10-20 r.u. per liter, per day.

The usual method of isolation of theelin is to extract acidified urine with a lipoidal solvent, in our case ethyl-acetate, and then remove it from the solvent with dilute NaOH. Further purification depends upon solution in benzine, ether and ethyl acetate. In 1929 Professor Clarke and I isolated 40 milligrams of crystalline theelin, containing about a quarter of a million rat units from three tons of pregnant urine.

For clinical purposes Professor Clarke and I have devised the following method of extraction: The urine after acidifying is saturated with NaCl and extracted with ethyl acetate. The ethyl acetate is then distilled off in vacuo and the residue transferred to a given amount of olive oil. Various amounts of this oil are then injected into castrated rats.

PHYSICAL PROPERTIES OF THEELIN

Theelin is a crystalline substance with a melting point of 254. Its formula is $C_{18}H_{22}O_2$. It is a ketomonoatomic alcohol, containing one OH group and a carbonyl group. It contains one double bond. Theelin is stable towards heat and cold. Treatment with acids and alkalis do not injure it. It is water soluble, dialyzable and readily absorbable. It is interesting to note that crystalline testicular hormone has a formula of $C_{16}H_{26}O_2$ and the conversion of this substance into theelin or vice versa by the body is a distinct possibility. (Possibly by the adrenal cor-

tex in cases of virilism—theelin may be converted into testicular hormone and thus the secondary sex characteristics of these women modified.)

THE BIOLOGICAL ACTIONS OF THEELIN

1. Upon the castrate—produce estrus.
2. Upon the immature animal—produces a single estrus cycle. There is no effect upon the ovaries, the action being limited to the uterus and vagina.
3. When injected into a normal adult in large doses the normal rhythm is broken and the animal remains in constant estrus.
4. Upon the human endometrium—theelin is responsible for the post-menstrual or proliferative phase of the endometrial cycle. It never produces the pregravid phase but sensitizes the endometrium for the subsequent action of corpus luteum hormone (progesterone).
5. Upon the senile animal—when theelin is given to an immature animal one estrus cycle occurs and then the animal returns to its previous resting stage. Sexual maturity is never hurried and the animal reaches sexual maturity at the same time as the untreated litter mate. In the senile animal the single estrus cycle thus produced is followed by a rhythm of cycles lasting over a period of weeks (rejuvenation?).
6. Upon the breast—stimulates the growth of the breast. This is further augmented by the corpus luteum.
7. The anti-masculine effect—large doses produce inhibition of testicular growth in young males. (Very large doses of theelin produce degenerative changes in immature ovaries.)
8. Metabolic rate—very moderately increased.
9. Upon the uterus—in the guinea pig theelin sensitizes the uterus to the action of pituitrin. It has been proposed as the etiological factor for the onset of labor, in view of its increasing concentration as labor approaches. I have been unable to demonstrate this sensitization in the human.

THE CORPUS LUTEUM HORMONES

Our knowledge concerning the corpus luteum hormones is more fragmentary than that of theelin. They have not been isolated in pure form, and we know them only through their physiological activities. Two hormones besides theelin have been isolated from the corpus luteum.

1. Progesterone or lutein—a hormone that causes the pregravid changes in the endometrium and probably inhibits ovulation.
2. Relaxin—a hormone causing marked relaxation of the pelvic ligaments in the guinea pig. It may be responsible for the relaxation of the pelvic girdle during pregnancy.

Recently Knaus demonstrated that in the rabbit uterine contractions during the first half of

pregnancy are inhibited by progestin, thus favoring secure nidation of the ovum. Early removal of the corpus luteum of pregnancy is followed by abortion.

Menstruation and estrous have certain features in common, but they are not the same phenomena. The uterine hemorrhage in menstruation is merely an external sign of a process which involves the whole organism. A number of hormones (five, possibly six) are directly responsible for the cyclic ovarian and uterine changes.

Figure 1 gives a tentative idea of the hormones that are involved in the normal menstrual cycle, their probable number, origin, function, cyclical activity and interrelationship. It can be seen that theelin is responsible for only one phase in this cycle, that is, the proliferative or postmenstrual phase. Female sex hormone is produced throughout the cycle, although its action during the premenstrual phase is not clear. In a functional disorder of the genital tract one or more hormones may be involved. It is therefore wrong to give theelin for every functional disorder, and the hormone is only indicated when it is deficient in amount or absent. Furthermore, because of the antagonism between some of these hormones, advantage may be taken of this therapeutically, for, where one hormone is showing hyperactivity, the inhibiting hormone may be used to depress it.

In a previous publication⁸ we have shown a method of approach to the study of some of the functional disorders that is now in use at the Sloane Hospital for Women. The basis for the classification of these disorders is the following group of facts.

1. Every normal woman excretes throughout her menstrual cycle ten to twenty rat units of theelin per liter of urine.

2. This excretion is fairly constant throughout the cycle, with some variation during the cycle, but remains within the above limits.

3. The quantitative demonstration of theelin in the urine as at the present time one of the best methods of determining ovarian (follicular) activity.

4. The follicle stimulating hormone (Prolan A) from the anterior pituitary gland is normally not found in the urine (by the method described), but can be demonstrated when the ovary ceases to function completely (castration, etc.).

The theelin in the urine is determined by the method of Kurzrok and Ratner,⁹ based on a method of obtaining crystalline female sex hormone (Clarke and Kurzrok¹⁰). Prolan A is determined by the method of Zondek.¹¹

If we determine the presence and absence of both theelin and the follicle stimulating hormone in the urine four types of excretion are possible, and based on these different types, distinct forms of therapy are indicated.

TYPE I

1. Theelin—present. Follicle Stimulating Hormone—absent.
 - A. Theelin—10 to 20 rat units per liter. Normal function—usually. Occasionally amenorrhea (isohormonal type).
 - B. Theelin—less than 10 rat units per liter. Hypofunction with hypomenorrhea, oligomenorrhea or amenorrhea (hypohormonal type).
 - C. Theelin—greater than 20 rat units per liter. Amenorrhea (polyhormonal type of Zondek). Poly and hypermenorrhea. Cystic and glandular hyperplasia of the endometrium.

Therapy:

In the isohormonal and hyperhormonal type of amenorrhea theelin is not indicated, for it is produced in normal, or greater than normal, quantities. We have recently given the luteinizing hormone of the anterior pituitary with good effect. The hypomenorrheas give excellent results with theelin and with the gonadal stimulating hormones (Prolan or Follutin). The excessive bleeding in cystic and glandular hyperplasia of the endometrium is due to an excess of theelin, and therefore its use therapeutically is contraindicated. Advantage may be taken of the antagonistic hormones, Prolan B or lutein. The latter is not as yet on the market, but Prolan B is found either in Prolan or Follutin (combined with Prolan A) or in a purer form combined with the body growth hormone. Novak has reported excellent results with this form of therapy and our own results are equally encouraging.

TYPE II

1. Theelin—absent. Follicle stimulating hormone—absent. Hypofunction, amenorrhea, hypomenorrhea or oligomenorrhea. Some severe menstrual headaches.

Therapy:

This type is an extension of the hypofunction already described in Type I, B. In cases of ovarian hypofunction one must remember that the defect may primarily be in the anterior pituitary gland. This gland is the motor of the genital system. Prolan A stimulates the ovary to form follicles, and these in turn produce female sex hormone and the latter acts upon the endometrium. Shall we therefore give ovarian hormone as substitution therapy or give prolان A which will stimulate the follicular apparatus, or both? We usually give both. But it must be remembered that very large doses of theelin may depress the production of the follicle stimulat-

FIG 1 Hormones involved in normal menstruation, and the cycle of ovarian and uterine activities

ing hormone, and may also produce generative changes in hypoplastic ovaries.

TYPE III

1. Theelin—absent. Follicle stimulating hormone—present.
Cessation of ovarian function—castration, radiation, menopause precox, spontaneous menopause.
Very severe headaches.
(Ahormonal amenorrhea.)

Therapy:

Theelin is indicated in all of the above symptom complexes. Prolan A is contra-indicated, for it is already produced in excessive amounts, and is not utilized because of the absence of active ovarian tissue. We have found that there are two types of spontaneous menopause, depending upon the presence or absence of ovarian hormone in the urine. Theelin is only of benefit where no female sex hormone is produced, and one gets the impression that when it is given to those cases that produce it spontaneously the patient's symptoms are often made worse. Our experience has been that a small amount of theelin dissolved in oil is more efficacious in the treatment of menopause than larger doses dissolved in water.

TYPE IV

1. Theelin—present. Follicle stimulating hormone—present.
Pregnancy.
Genital carcinoma in women of child-bearing age.
Occasionally in some glandular syndromes—thyroid, pituitary.

Therapy:

Only the last group is in need of glandular therapy and our experience here is far too limited to express an opinion.

Theelin has been used in almost all functional disorders. This is physiologically wrong. For example, in the amenorrheas in which theelin is involved, it is indicated only in the ahormonal and hypohormonal types, and contra-indicated in the isohormonal and hyperhormonal types. In judging the clinical results of hormonal therapy one must remember that the production of spotting for a few hours does not necessarily mean that a menstrual period has been obtained. Intelligent women can readily differentiate between spotting and menstruation. Several menstrual periods occurring at fairly regular intervals must occur before a therapeutic result can be claimed.

Our knowledge of these hormones is still very fragmentary and often confusing. But enough has already been done to convince us that we are on the right track scientifically and clinically.

A NEW METHOD OF OUTLINING THE URINARY TRACT BY MEANS OF UROSELECTAN INJECTED INTRAVENOUSLY*

By OSWALD SWINNEY LOWSLEY, M.D., NEW YORK, N. Y.

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital.

UROSELECTAN

THE most recent striking advance in our armamentarium for examination and diagnosis of urological cases is the discovery and utilization of Uroselectan. This is a drug which may be injected intravenously under proper precautions and thus far, in the experience of a great many skilled hands, has failed to show any toxicity. Uroselectan is excreted by the urinary organs in sufficient quantity to show fairly well in radiograms taken at certain intervals and gives promise of being a particularly useful method in selected cases.

This drug, oxyiodopyridin acetic acid, was

synthesized by Prof. Bintz and Dr. R  th of the Landwirtschaftliche Hochschule of Berlin (Chemical Institute) in 1927. It contains 42 per cent of organically combined iodine. Its use in outlining the kidney pelvis was developed in the department of Urology at St. Hedwig's Hospital in Berlin.

It is particularly interesting that Professor A. Von Lichtenberg has been influential in this latest development in the diagnosis of renal lesions as he was in the first pyelography taken. In 1905 Von Lichtenberg conceived the idea that it would be helpful to outline the kidney pelvis by injecting a shadow casting solution in the kidney through an ureteral catheter and take an x-ray picture. He discussed the matter with Prof.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

Voelker and they decided to cystoscope and pyelograph each other.

Prof. Voelker then proceeded to cystoscope, catheterize, and inject collargol into Von Lichtenberg's kidney. An x-ray revealed a beautiful outline of the kidney pelvis and an epoch-making discovery had been made. Von Lichtenberg prepared to repeat the experiment on Voelker and the latter promptly decided that the experiment was thoroughly successful and they could now practice the method without further experimentation on himself.

This same Prof. Von Lichtenberg is now influential in the latest epoch-making discovery, in the diagnosis of renal lesions, a quarter of a century after his first work.

Others to be mentioned in connection with this study are Binz and R  th who synthesized the drug; and Swick of New York, who working in Von Lichtenberg's clinic, actually made the first successful intravenous pyelogram with Uroselectan.

In this connection it is well to call your attention to the fact that this is not an accidental discovery, but a successful culmination of years of effort by a large number of workers.

In 1923 Osborne, Sutherland, Scholl, and Rowntree were the first to attempt the visualization of the urinary tract by means of intravenous injection of a 10 per cent solution of sodium iodide. In 1924 Rosenstein and Von Lichtenberg repeated the work with iodide in conjunction with the perirenal pneumo-radiographic method of Rosenstein. Volkmann, in 1924, Lenardouzzi and Pecco in 1927, have also given an account of their findings. Hryntschak, at a congress in 1928

and in the Zeitschrift fur Urologie, 1929, reported his work. Finally, Roseno by means of the intravenous use of a substance containing sodium iodide bound to urea, was the first to achieve practical results but apparently associated with some reactions

FIGURE 2.

A. Shows the outline of the two kidneys markedly accentuated by Uroselectan. The pyelogram and the left ureterogram are beautifully shown.

B. A retrograde pyelogram shows the pelvis of the right kidney better than the Uroselectan pictures, but does not outline the kidney shadows at all.

Selectan neutral also synthesized by Binz and Rath in 1927 was used in combating coccus infections on the medical service of Prof. Lichtwitz at the St  disches Krankenhaus, Hamburg, Altona. The study of its excretion and its iodine content (54%) made it seem possible that it might be visualized by means of the x-ray. Animal experimentation made it seem applicable to man, but when attempted, its intravenous administration was accompanied by headache, nausea, vomiting and in two cases diplopia. Oral and rectal administration yielded the same results both as regards the pictures obtained and the toxic manifestations. So it was given up. A modification of Uroselectan called neo-iopex has just been brought out which gives even better pictures than the original drug.

THE TECHNIC OF ADMINISTRATION OF UROSELECTAN

The contents of one bottle of Uroselectan (40 grams) are dissolved in 110 c.c. of double distilled water and the solution is filtered twice through ordinary filter paper. The solution is then sterilized in an autoclave under 15 pounds pressure for 30 minutes. The sterilized solution is then given intravenously by the multiple syringe method using 4—30 c.c. syringes. The total time for the administration of the entire amount should be not less than five minutes. Pictures are then taken at intervals of 10 minutes, 30 minutes, one hour, and two hours, following administration.

FIGURE 1

A. Shows a bilateral retrograde pyelogram. The left kidney is ectopic, hydronephrotic and contained twenty-one stones. It was removed transperitoneally.

B. Is the same case one and a half hours after the intravenous injection of iopax (Uroselectan). It shows accurately the shadow of the right kidney pelvis but only a little of the solution is collected in the enlarged left ectopic organ. This is due to the great diminution in its function and demonstrates one of the limitations of the method.

These intervals may be varied however, depending upon the kidney function. In case of very poor kidney function it may be advisable to take pictures several hours following administration of Uroselectan.

The preparation of the patient consists of giving a dose of castor oil about 24 hours preceding administration and one glass of water about half an hour preceding administration.

FIGURE 3.

A. This was a particularly helpful Uroselectan picture. The tumor of the right kidney is very poorly shown, but the fact that there was a hydronephrosis of the left kidney was unknown until this picture was taken. Dilation of the left ureter and proper drainage of the left kidney made it possible to remove the cancer on the right side with impunity.

B. Shows the tumor of the right kidney beautifully by retrograde pyelography.

The solution may also be sterilized by boiling for ten minutes; but in this case there is a loss of about 10 per cent of the Uroselectan.

Uroselectan is absolutely non-toxic, neutral in reaction, readily soluble in water, and its tolerance is exceedingly great.

Under normal conditions, 95 per cent should be excreted within 6 to 8 hours. About three-fifths of the substance is excreted during the first 2 hours, one-quarter during the next hour, and the remainder in another 4 hours. In the case of diseased or damaged kidneys, the rate of excretion is proportionately decreased, and the substance has been found in the urine as late as 6 to 8 days after injection when stasis has been present. The specific gravity of the urine in normal kidneys is greatly increased, often reaching as high as 1040 or 1045 within a few hours after injection, whereas such is not the case in the presence of diseased organs. A child of 7 years of age receives one-half the adult dose which is 40 grams; and a patient of 2 years, one-quarter of the dose. The youngest patient ever injected was an infant of five months. Compression by means of an inflated rubber bag over the bladder region 10 minutes prior to and during the time

of roentgenographic exposures, markedly intensifies the pyelograms.

The cases examined in this study consisted of men, women and children of all ages. There were 167 altogether of these, six were youths and children. About 60% of the cases were males and 40% females.

There was a great divergence in the ages of the patients, the youngest a child of 5 months and the oldest was a much talked of personage, the famous old man of Turkey, Zaro Agha, 156 years of age. The average age of all patients examined was 36 years.

This method was of great aid in making a correct diagnosis in 117 cases, and apparently of no assistance in 50 instances.

It seemed to be of great importance to determine the best time for making the radiographic exposures. We therefore took pictures at 5-minute intervals after injection, until the end of an hour. Again at 2 hours, 3 hours, 4 hours, and 5 hours. It was found that only on the rarest occasions did one secure any worthwhile picture in 5 minutes. Frequently a 15-minute exposure would be excellent, but in most instances where there was no obstruction the best radiogram was obtained between the 20 and 30-minute period. In cases of hydronephrosis or other obstructive lesions, the shadow may be observable for very long periods of time, frequently as long as 5 hours after injection.

FIGURE 4.

A. Shows the dilated ureter pelvis, and calyces above a calculus in the left ureter opposite the transverse process of the third lumbar vertebra by the intravenous method which it was impossible to delineate by the retrograde method as shown in B.

Untoward Results. There have been no serious accidents of any sort connected with the injection of Uroselectan and the untoward results have been very slight. Two cases had no unusual sensations whatever. 165 mention a sensation of warmth pervading the body. Nine patients ex-

perienced nausea, but only two of these vomited. Thirteen experienced a choking sensation. One patient had an excess of mucus in the throat, another noticed a frequency of urination and 41 in the entire series experienced pain in the arm during the injection of the solution.

The results of our experience with this drug indicate that intravenous pyelography will in no way displace cystoscopy as a diagnostic procedure, nor will it in the ordinary investigation relieve us from doing a pyelogram by means of injecting solutions through the ureteral catheter when indicated.

FIGURE 5.

A. Shows the Uroselectan picture of a child. The left kidney is destroyed. The right kidney and ureter are well within normal limits.

B. Shows a retrograde pyelogram of the diseased kidney. The insert shows the pyelogram of the kidney pelvis after removal. This is particularly helpful in showing the normal right kidney and is an illustration of the saving of an extra cystoscopy.

There are certain cases, however, in which cystoscopy would be considered a major procedure and distinctly contra-indicated except under the gravest necessity. Such cases might be subjected to intravenous pyelography without harm and with the possibility of decidedly beneficial information being obtained. In children suffering from upper urinary tract lesions, cystoscopy, even with the splendid Butterfield's child's cystoscope, requires a general anesthetic, thus making it a major surgical procedure. In certain aged or very ill patients cystoscopy is contra-indicated also.

In patients who have had the ureters transplanted into the bowel, catheterization of the ureters is impossible, and intravenous Uroselectan becomes the only method of visualizing the urinary tract.

Pyelograms made with Uroselectan and sterile water in equal parts by injecting the solution through a ureteral catheter give fair pictures and do not cause as much irritation as sodium iodide

Also in the presence of hematuria Uroselectan is particularly helpful.

Contra-indications for its use. In case of grave renal dysfunction, it is not advisable. Two deaths of children have been reported after its use, but the deaths cannot be specifically ascribed to its administration.

By the use of Uroselectan delay in visualization and excavation of the kidney cortex may be noted, as well as granular encroachment on the lumen of the kidney pelvis and ureter. In this manner a very good idea of the presence and extent of tuberculosis lesions may be estimated.

Most cases of urinary tuberculosis come to the surgeon because of vesical irritation as symptoms occur early, persist throughout the disease, and are not amenable to any form of treatment except in rare instances. The vesical irritation which accompanies these symptoms makes cystoscopy painful, and in some instances dangerous, as several cases of vesical rupture have been reported.

Various types of anesthesia are used, all of which are accompanied by a certain element of danger. Also there is edema of the vesical mucosa, particularly in the region of the ureteral orifices, which makes catheterization of the ureters difficult and in some instances impossible. In such cases Uroselectan is of inestimable value.

In cases of bilateral tuberculosis of the kidneys, it is frequently deemed advisable to remove the worst kidney; and the patients often profit from such a procedure. The use of Uroselectan to visualize the condition of the remaining kidney is a very great addition to our armamentarium.

Certain tuberculous patients are in such serious general condition that any investigation as rigorous as a cystoscopy is precluded. The information obtained by intravenous pyelography is frequently so useful that further investigation is unnecessary. The case shown in Fig. IV is one of this sort and is an excellent example of the marvelous efficiency of the method. Uroselectan is particularly helpful in the differential diagnosis between stone in a kidney calyx, a calcified renal cortical abscess, and an extra-urinary shadow. Indeed, in such a case this method is superior to any other, because a pyelogram does not accentuate the renal cortical structure as Uroselectan does, thus making a tubercular abscess in the cortex stand out in a most interesting manner.

It is unquestionably true that intravenous pyelography does not give as clear cut pictures as those obtained by injecting sodium iodide from below; but the circumstances which allow the use of the intravenous method are so numerous when the old fashioned method is dangerous or impossible that this drug opens up a new field of diagnosis which is epoch-making, and is one of the most important contributions ever made in urological diagnosis.

THE VALUE OF AN EQUILIBRATED SALT DIET IN THE TREATMENT OF VARIOUS DERMATOSES

A Modification of the Herrmannsdorfer-Sauerbruch-Gerson Diets.

By JOSEPH JORDAN ELLER, M.D., AND CHARLES ROBERT REIN, M.D., NEW YORK, N. Y.

WITHIN recent years renewed attention has been directed to the restriction of sodium chloride in the treatment of various diseases. The impetus was given several years ago by Max Gerson, who proposed salt-poor nutrition in the treatment of tuberculosis. His results attracted the attention of Sauerbruch and Herrmannsdorfer, who subjected Gerson's dietary proposals to wide experimental and clinical research and subsequently modified them in certain respects. To Sauerbruch belongs the credit for having perceived the true import of Gerson's proposals and for their introduction into medical practice.

It may be well to summarize briefly the characteristics of the Gerson^{1, 2} and Herrmannsdorfer-Sauerbruch^{3, 4} diets, whose chief differences are shown in the accompanying table. It is necessary to bear in mind that Gerson has also modified his original diet so that when we now speak of the Gerson diet we mean the modified and not the original form of the same.

Both diets are salt-poor. No table salt is added to the foods either in cooking or on the table and no manufactured foods containing table salt are employed. The diets therefore contain only the relatively small amounts of sodium chloride naturally present in the raw foods. The sodium chloride content of both diets is probably about 3-4 grams daily and will vary with the raw materials and the total food intake.

Both diets prepare the foods by methods which assure a high vitamin and mineral content. Both are fat-rich but carbohydrate-poor. They differ greatly as regards protein, which is low in the Gerson diet and moderately high in the Herrmannsdorfer-Sauerbruch diet. There are certain minor differences in respect to permitted and prohibited foods and the preparation of certain foods. The fluid requirement is covered mainly by milk in the Herrmannsdorfer-Sauerbruch diet and almost entirely by juices extracted from raw vegetables and raw fruit in the Gerson diet. The Gerson diet makes use of occasional raw food days on which only uncooked foods are permitted. The Gerson diet is alkaline-ash, while the Herrmannsdorfer-Sauerbruch diet claims to be acid-ash and to be capable of shifting the tissue reaction feebly to the acid side of the equilibrium. Both diets employ similar medication, consisting of the oral administration of a mineral mixture proposed by Gerson, and a phosphorized codliver oil containing vitamins A and D. Besides these medicaments Gerson also employs at times certain hormones and an irradiated codliver oil.

A distinctive feature of the Herrmannsdorfer-Sauerbruch diet is that the relative proportions of protein, fat and carbohydrate are fixed. The proportion now employed in this diet is as 1.5:2.7:4 per kilogram of bodyweight, exclusive of codliver oil.

Both diets seek to dehydrate the tissues and to modify the body's mineral balance. Sauerbruch and Herrmannsdorfer have confined the use of their diet almost entirely to the treatment of tuberculosis while Gerson employs his diet not only in tuberculosis but also in other diseases including various dermatoses.

Gerson,⁵ Sauerbruch and Herrmannsdorfer,⁶ Schueller⁷ and others reported favorable results in bone, joint and pulmonary tuberculosis. Volk,^{8, 9} Jaffe and Steffens,¹⁰ Blumenthal,¹¹ Wichmann,¹² Jesionek,^{13, 14} Doerffel¹⁵ and Bommer^{16, 17, 18} have reported favorable results in skin tuberculosis.

There is considerable controversy in Germany over the value of the salt-restricted diets in pulmonary tuberculosis. In this country Emerson¹⁹ and Banyai²⁰ used modified Gerson-Herrmannsdorfer-Sauerbruch diets in the treatment of pulmonary tuberculosis with fair results. Mayer²¹ employed the original Gerson diet on a selected group of patients with pulmonary tuberculosis with apparently good results. He has reviewed the question of salt-restricted dietary in tuberculosis and concludes that although it offers a distinct therapeutic advance in the treatment of lupus and is capable of raising the resistance of pulmonary patients, considerably more investigative work must be done before definite conclusions regarding its value could be reached. The Herrmannsdorfer-Sauerbruch diet is now being tried out in several institutions on pulmonary patients.

Jesionek and Bommer^{10, 17, 18} have reported striking curative results with the Herrmannsdorfer-Sauerbruch diet in the treatment of a large series of lupus vulgaris cases and other types of skin tuberculosis at the Giessen Lupus Clinic.

More recently Doerffel²² has carried out the Herrmannsdorfer-Sauerbruch diet in 51 patients with skin tuberculosis. Careful microscopic, macroscopic, chemical and cultural studies were made. In the great majority of these cases the results were reported excellent. In the favorable cases the lesions healed with remarkably good cosmetic results. Characteristic healing changes, decreased virulence or complete disappearance of tubercle bacilli and a favorable effect on the entire organism were noted. The skin

showed dehydration and alteration of the ionic balance associated with an increased potassium content. Doerffel concludes that the change produced by the diet on the mineral ratio was an important factor in healing.

The difficulties attending the use of a diet in which all sodium chloride must be excluded are well known. The desire for salt is deeply rooted in nearly all races in every quarter of the globe, and its withdrawal causes great and undeniable hardships. Rendering unsalted foods acceptable to patients for prolonged periods demands skillful culinary procedures with pleasing and varied presentation of the foods. In such a diet the kitchen assumes decisive importance. But besides this there must be constant vigilant supervision by the physician as well as strictest co-operation of the patient to attain successful results. If these pre-requisites be difficult to fulfill in institutions, that difficulty becomes vastly accentuated in ambulatory patients.

Attempts to render unsalted food adequately palatable by means of table salt substitutes have proved unsatisfactory. These preparations contain no sodium chloride but other substances with a more or less salty taste. Some of them possess but feeble seasoning power or leave an unpleasant after-taste; others with better seasoning power cannot be used except in very small quantities.

The necessity for assuring palatability and the failure to find adequate table salt substitutes led to increasing use of various other seasoning and flavoring agents and special culinary procedures to make up for the lack of table salt. Strauss first suggested many seasoning and flavoring agents and procedures. Gerson has given many directions for securing palatability, and M. Herrmannsdorfer⁴ has worked out additional skillful methods which largely mask the withdrawal of table salt.

In regard to the loss of palatability from table salt withdrawal, a recent new development is of considerable interest to dermatologists and may possibly prove of great value.

Keining and Hopf^{23, 24} recently investigated the role of table salt in nutrition in relation to the so-called sympathetic dermatoses. They found that various dermatoses show marked hypersensitivity toward sodium chloride. When eczema and urticaria patients were flooded with sodium chloride by mouth, following several days' salt-free feeding, they nearly always showed a marked exacerbation of symptoms. This procedure often gave the patients severe shock and the salt-flooding had to be promptly discontinued. The itching usually became unbearable. In addition it was shown that intracutaneous injection of isotonic salt solution produced wheals at the site of injection, while no wheals were produced with osmotically equi-

brated glucose solution in the same patients. Experiments to determine whether the sodium or the chlorine was responsible, demonstrated that the cation and not the anion was the irritating factor. Consequently the authors attempted to remove the irritative action from table salt. Proceeding from the known antagonism between certain cations they developed what they term a physiologically equilibrated salt-mixture. This is based on the fact that sodium is the harmful component and that it can be rendered perfectly harmless to the organism by bringing it into definite proportional relationship with sodium-detoxifying cations, viz., potassium, calcium and magnesium cations. The cation relation of this mixture was found to correspond very closely to the cation relation of the blood serum.

When Keining and Hopf injected this equilibrated salt it produced no wheals or only very feeble reactions in the same patients in whom wheals had previously been obtained with injection of isotonic salt solution. Despite the high sodium content of this mixture it failed to exacerbate symptoms when it was given in large amounts by mouth, in those patients who had previously shown great exacerbation following sodium chloride flooding by mouth. Apparently, therefore, this mixture overcame the previous hypersensitivity toward sodium chloride. It has the following formula:

Sodium	32.51%	Chloride	52.63%
Calcium	1.42%	Lactate	3.79%
Magnesium ...	0.86%	Citrate	0.50%
Potassium	2.7 %		

Keining and Hopf²⁵ claim favorable results with the vitamin-rich and mineral-rich diet salted exclusively with this equilibrated salt mixture in a variety of dermatoses such as urticaria, eczema, acne vulgaris, acne rosacea, erythema induratum, Duhring's disease, certain tuberculids and lupus vulgaris. In 18 cases of lupus vulgaris the results were as satisfactory as those obtained by Jesionek and Bommer with the Herrmannsdorfer-Sauerbruch salt-poor diet. Bommer²⁶ treated 33 lupus vulgaris patients with a salt-restricted diet which was prepared precisely as directed by Herrmannsdorfer excepting that the foods were salted with this equilibrated salt. He claims for this treatment the same curative results in lupus as for the Herrmannsdorfer-Sauerbruch salt-poor diet. Langer²⁷ has reported favorable results with the equilibrated salt diet in urticaria, eczema, pruritis, and particularly in dermatoses involving internal hypersensitivity.

The salient theoretical foundations of Keining and Hopf's modification of the Herrmannsdorfer-Sauerbruch-Gerson diets are the following:

Keining and Hopf believe that the chemical composition of ordinary table salt is faulty. In

nature, whether in human or animal blood, in sea-water, or in the sources from which table salt is derived, sodium chloride always occurs associated with potassium, calcium and magnesium combinations. But the refining processes to which natural salt is subjected deprive it almost entirely of these constituents and yield a highly refined artificial product consisting of practically pure sodium chloride. Long continued daily intake of this refined product may derange the normal cation relation in some individuals, with the result that in them sodium is enriched, while potassium, calcium and magnesium become impoverished. Abnormal cation relations affect the colloidal structure of cells, altering the response of these cells to stimuli, disturbing stimuli conduction and leading to sympathetic disturbances. Table salt restriction, which reduces the sodium intake, tends to restore normal cation relations. Similarly, the equilibrated salt mixture likewise tends to re-establish normal cation relations because its sodium content is detoxicated. While the action of a salt-restricted diet and that of a diet salted with this equilibrated salt appears to be analogous, the palatability and assimilability of their constituent foods will differ widely. If it were possible to season foods with a mixture containing 80% of sodium chloride, without however exposing the patient to sodium injury, the use of a diet from which all table salt has to be excluded would be greatly facilitated. This has recently been emphasized by Von Noorden²⁸ from the standpoint of dietetics. Inasmuch as table salt must not be ingested it is necessary to prohibit not only the intake of table salt as a condiment but also foods that have been manufactured with table salt, such as ordinary bread, salted butter, boiled ham, corned beef, etc. If, however, these foods can be prepared with equilibrated salt instead of with table salt their use could be permitted.

The fact that serious health injuries rarely result from the daily consumption of considerable amounts of table salt is believed to show that the body possesses sodium-detoxicating mechanisms. These mechanisms are assumed to depend on the body's capacity for bringing sodium into relation with antagonistic cations.

In a personal communication Keining and Hopf state that they have investigated the action of the equilibrated salt on the water metabolism. They found it does not cause water retention in normal people. Consequently they suggest its employment in sub-acute and chronic nephritic and also in cardiac and circulatory conditions in which table salt is contraindicated. If confirmed, this would do away with the necessity for putting such patients on unpalatable salt-poor nutrition.

Though we have ourselves employed the Herrmannsdorfer-Sauerbruch unsalted diet in skin cases, we felt that the greater palatability obtain-

able by the use of the equilibrated salt mixture would facilitate the application of table salt restriction in such patients. Accordingly we treated various dermatoses with this diet as directed by Keining and Hopf.²⁹ The detailed procedure is as follows:

The patient is put on a salt-free diet for about eight days. On the fourth day of this regimen he is given a sodium chloride "thrust" in the form of 5 grams sodium chloride three or four times daily, by mouth, in little water, masked by menthol. The salt thrust is continued for from 1-3 days, as needed, to observe the reaction. The patient is then put back on salt-free feeding another 3 days. He is then given a physiologically equilibrated potassium, calcium and magnesium cation mixture by mouth for several days, also under salt-free nutrition, whereby the exacerbation which usually occurs due to "salt thrust" fades. Following the cation thrust days, the patient is placed on a diet from which all table salt is rigidly excluded and which is salted exclusively with the equilibrated salt mixture. This dietary treatment is supported by oral or parenteral administration of the aforementioned cation mixture until the acute symptoms have faded. The cation mixture is specifically intended to accelerate a preponderance of potassium, calcium, and magnesium as against sodium. It is important to use a diet which is rich in vitamins and minerals. In this connection Bommer's³⁰ views on the effects of the Herrmannsdorfer-Sauerbruch diet in lupus are of interest. He states that neither salt withdrawal alone nor vitamin-rich foods alone can account for the curative effects but that those two factors must operate concurrently. Blumenthal¹¹ gave lupus patients a vitamin-rich diet salted with table salt and also an irradiated ergosterol preparation without achieving successful results. Bommer on the other hand fed lupus patients a vitamin-poor diet without table salt and had no results that could be compared with those obtained under the vitamin-rich and salt-restricted Herrmannsdorfer-Sauerbruch diet.

While dehydration and mineral balance are the cardinal objectives of the salt-restricted dietaries, the precise mechanism of the latter has so far escaped elucidation. Various theories have been propounded. Bommer believes that simultaneous table salt restriction and vitamin-richness restores the functions of the capillary wall cells, and that all other curative processes may be regarded as following from this action. Only when the ionic environment of the vascular wall cells has returned to normal physiologic relations can the vitamins unfold their full effects. Apparently vitamin intake and salt regulation mutually support and favor each other's action.

Grote³⁰ regards the dehydrating action of salt withdrawal as the leading factor in the favorable

effects of the salt-restricted dietaries. This view is also shared by Strauss²¹ and others. Von Noorden²² assigns great significance to the preponderance of the calcium-ion in the tissues, resulting from the decrease of sodium chloride, and to the antiphlogistic action of the calcium.

In connection with the role of calcium, a personal communication from Keining and Hopf, referring to researches by Dittman and Von Baeyer,²³ is of interest. They showed that the skin's inflammatory capacity is increased when calcium-precipitating agents are brushed into the skin. Keining and Hopf have extended these researches by testing a large number of patients with local applications of definite salt solutions, which were brushed into the skin. When more sodium was thus introduced, or when calcium-precipitating and magnesium-precipitating agents were brushed in, erythema (from regulated ultra-violet radiation) was increased. On the other hand the erythema reaction was not influenced by chlorides, acids or alkalies. That the cation environment directly influences the cell was shown also when novocain solution was brushed into the skin, which paralyzes the sympathetic nerve-endings but does not influence the erythema capacity.

RESULTS

Our personal experience with the equilibrated salt mixture diet was limited to 12 cases including 2 cases with lupus vulgaris, 2 with lichen planus, 4 with chronic eczemas of unknown etiology, 2 with urticaria, and 2 with acne vulgaris.

The patients with lichen planus, urticaria and eczema showed definite improvement under salt-free nutrition but marked exacerbation of the symptoms when the sodium chloride thrust was employed. These patients again improved when they were put on a diet from which all table salt was excluded but which was salted exclusively with the equilibrated salt.

The 2 cases of lichen planus continued to improve for some time. The intense pruritis in both cases had almost entirely subsided. No new lesions appeared but the old lesions remained stationary.

Both patients with urticaria became free of symptoms and have remained free during this study. This favorable response may be due to an influence of the equilibrated salt mixture diet on the calcium metabolism.

The 2 eczema cases had become entirely free of the skin lesions and have remained free during the study. The other 2 cases were unaffected by this diet.

The patients with lupus vulgaris and acne vulgaris showed no change during the salt thrust and were unaffected by the diet. In most of these cases we were unable to obtain the patients' strict and long-continued cooperation.

In attempting to appraise the results we realize the difficulty of making fair comparison of

our results in few cases with those reported by Keining and Hopf on large series. And whereas the German authors were able to hospitalize many cases our own patients were all ambulatory ones. Full allowance must be made for this. Keining and Hopf distinctly stated that their ambulatory patients frequently failed to follow the dietary directions conscientiously and that the percentage of favorable results was considerably higher in the hospitalized cases. Further, it was not possible for us to satisfy all of Keining and Hopf's requirements. For instance, they stress the great importance of a thorough clinical examination of the sympathetic disturbance in order to arrive at a clear conception of its nature before the dietary treatment is instituted. We were unable to carry this out on the ambulatory patients though the salt thrusts and cation thrusts were given whenever possible.

While the equilibrated salt diet offers palatability of all the foods and therefore removes the chief hardships pertaining to table salt restriction, it nevertheless necessitates constant conscientious cooperation on the part of patients. The necessity for excluding all foods containing table salt renders the application of the diet in skin patients who take meals away from home a matter of greatest difficulty, just as in the case of the unsalted Hermannsdorfer-Sauerbruch-Gerson diets. The difficulty may be partly overcome by the regular intake of the cation mixture in tablet form before meals, which to some extent compensates for undesired table salt ingestion. In such patients this dietary treatment will however probably prove unsatisfactory and the results inconclusive. To arrive at a just estimate of its capabilities it will be necessary and desirable to apply it in well-controlled institutionalized patients, though, given proper cooperation, it can be carried through satisfactorily in patients' homes.

From our preliminary study of the Keining and Hopf equilibrated salt diet on ambulatory patients we have nevertheless gained the impression that when properly applied it should constitute a useful and valuable additional form of therapy in selected dermatoses.

We wish to acknowledge the assistance which was rendered to us by Mr. Robert Wollheim in the course of this preliminary investigation of the equilibrated salt diet of Keining and Hopf. Mr. Wollheim has long identified himself with the dietetic aspects of salt-restriction, particularly in relation to the Hermannsdorfer-Sauerbruch-Gerson salt-poor tuberculosis diets. In our work with these and with the Keining and Hopf equilibrated salt diet he worked out suitable regimens and special directions for the different cases and was also instrumental in obtaining for us the requisite quantities of the equilibrated salt mixture (Titro Dietetic Salt) and of the equilibrated cation mixture.

Table* Showing Differences Between the Gerson and Hermannsdorfer-Sauerbruch Diets

	Gerson Diet	Hermannsdorfer-Sauerbruch Diet
Meat	At most 100 grams once a week.	500 grams weekly.
Viscera	Prohibited.	Spleen, liver, sweetbread, brain, kidney are recommended.
Fish	Only about 70 grams per week.	Permitted.
Milk	½ pint per day.	2½ pints per day.

* From "Kochbuch fuer Tuberkulose," by M. and A. Hermannsdorfer, Joh. A. Barth, Leipzig, 1931.

Protein	Daily average protein about 40 grams.	Daily average protein about 90 grams.
Fat	Moderate amounts.	160-200 grams per day.
Cream	Prohibited.	About ½ pint per day.
Carbohydrate.	Generous amounts.	200-240 grams per day.
Potatoes	Generous amounts.	At most 125 grams per day.
Eggs	Only yolk of egg.	Whole egg.
Raw food ...	Predominant constituent 3-4½ pints raw vegetables and raw fruit juices per day.	100 grams raw vegetables and ¼ lb. raw fruit per day.

UTILIZATION OF TONSIL CLINICS FOR DEVELOPING
BRONCHOSCOPIC ORIENTATION*

By ARTHUR F. HOLDING, M.D., ALBANY, N. Y.

ONE of the difficulties of bronchoscopy is that it is a rare and occasional procedure. It is hard to get enough experience so as to be able to do fast and skillful work in the emergencies when bronchoscopy is indicated. Bronchoscopy is usually conceded to be an emergency, and often a life-saving procedure. Therefore, there is a need of getting more experience in doing bronchoscopy so that the operator's muscle sense is trained, his orientation is natural, and he works without strain.

In the largest cities there are well-trained bronchoscopic teams who keep in constant practice on patients, dogs, rubber phantoms, and other devices, and for them the suggestions in this paper may be valueless. But for that great body of busy otolaryngologists in cities of the

second class and smaller communities who may find themselves called upon to do bronchoscopy perhaps once a month, it is necessary to invent ways to keep themselves bronchoscopically conscious, and in constant state of preparedness against the emergency of bronchoscopy whenever it may arise.

If one were in a medical center where post-tonsillectomy lung abscesses or decanulations after diphtheria or membranous croup were common, one might get some bronchoscopic training from these sources, but in practice we do not find lung abscesses as frequently as scientific medical literature would lead one to expect. Personally in a bronchoscopic experience of ten years we have only seen three cases of lung abscesses and one of these refused to be hospitalized for treatment. We also find that the tendency of the time is for the intubation and

* Read before the Eastern New York Eye, Ear, Nose, and Throat Association, January 9, 1932.

decantulation in cases of diphtheria to be done by the pediatricians, so this experience is lost to the otolaryngologist.

At our Hospital, as we did not have any member of our team available at all times to act as "head-holder," we early came to rely upon laryngeal suspension for delicate operation on the larynx, trachea and bronchi, and accustomed ourselves to sitting at the patient's head and doing tonsillectomies in this position. (Fig. I and II.) We use the Sluder method as modified by Beck,¹ or the dissection method in the manner

described by Crowe² for taking out the tonsils. (Fig. III.)

Regardless of what method we use for the removal of the tonsils, we use the Crowe position for the removal of the adenoids, removal of small pieces of tonsil tissue, control of bleeding, application of ligatures, inspection of field, etc. The Crowe position has all the advantages of the Rose³ position (Fig. IV.), trapping all blood, secretions and bits of tissue in the pouch formed by the naso-pharynx.

Later, we adopted the Haslinger⁴ head-rest (Fig. V.), with the suspension mouth gag as used by Crowe, the ether being pumped through a cannula in the tongue depressor. If the operation is a short one, we hold the gag by hand; if the operation is to be prolonged, we use the vertical and horizontal supports of the Lynch sus-

FIGURE III

Field of operation with the operator in the bronchoscopic position, depicted after the manner of Crowe.

pension apparatus to support the suspension mouth gag.

This technique was first suggested to the late Dr. W. T. Garretson, head of the Division of Eye, Ear, Nose and Throat, Henry Ford Hospital, Detroit, and since then has become the routine method of tonsillectomy at that Hospital. Whitney⁵ recently published a report entitled "Suspension Method of Tonsillectomy in 8,000 Cases."

The technique of intratracheal anaesthesia as devised by Flagg,⁶ was later adopted in the Ton-

sil Clinic at the Memorial Hospital (Albany, N. Y.) for all cases of surgery of the head and neck, and the general surgeons in our hospital are beginning to use the same method in head, neck and chest cases.

The experience of exposing the vocal cords by direct laryngoscopy in a large variety of cases, and slipping a canula through the larynx into the trachea in the Flagg anaesthesia method is valuable to the bronchoscopist.

In using the Flagg method in cases of tonsillectomy, the breathing canula obstructs the operative field to some extent, but it can be manipulated out of the field by being slipped under the tongue depressor of the mouth gag, or clamped to the side of the tongue depressor on the gag. This broadens the spatula of the mouth gag so that the annoyance of the tongue bellying over the edge of the tongue depressor is avoided.

FIGURE IV

Sagittal view, showing safety insured by dependent position of post-nasal space in this position.

The advantages of the Flagg inhalation anaesthesia as stated by him cannot be improved upon—they are:

- a. Elimination of complicated motor-driving apparatus, manometers, and devices for warming and heating ether vapor.
- b. An operating field free from escaping insufflated vapor.
- c. An operative field free from the anaesthetist.
- d. Normal respiratory rhythm and amplitude.
- e. Conservation of carbon-dioxide.

- f. Exclusion from the trachea and lungs of foreign matter, such as blood and vomitus.
- g. Ability to maintain the lightest anaesthesia.
- h. Complete control of artificial respiration by the simplest methods.
- i. A technique which makes available the maintenance of anaesthesia for operations on the nose and throat by ether, gas and oxygen, ethylene, or any combination of these agents.

From the moment of intubation, the patient falls under complete anaesthetic control—a control that is not effected by the subsequent operative procedure or position.

The adoption of the intratracheal inhalation as prescribed is calculated to change the complexion of operations on the upper air passages (as well as all head operations—author) by reducing the customary tension and haste of these operations by insuring full, continuous, unobstructed respiration, which results in a lowered blood pressure, and the reduction of bleeding at the operative site by preventing cyanosis and the accidental aspiration of blood, vomitus, mucous, sponges, tissue, teeth, etc., during operation and thereby protecting the patient from postoperative pulmonary abscesses."

The above quotation describes just the conditions which a bronchoscopist wants and heretofore has found problematical of attainment in each case, so that there was an element of uncertainty—yes, even of fear before each case, because the patient's behavior was an unknown factor and as variable as human nature.

If all the preceding statements have failed to impress the experienced throat surgeon of the value of this position, I feel certain that the following statement will: when doing tonsillectomies on old chronic cases of quinsy, the kind that invariably bleed profusely, the operation is done with ease; the blood drains down into the naso-pharynx, away from operating field; this pool is removed by suction; the bleeding points can be readily seen and clamped; there is no repeated sponging and looking, and sponging and looking; the operating field is in full view of the operator all the time instead of being intermittently in view between the sponging; the operator sits at the head of the table looking down into the throat, much in the same way that the operating gynecologist does a plastic vaginal operation with the field exposed by speculum; the bleeding points are readily sutured and tied.

In over 10,000 cases of tonsillectomies operated by this method to date, there have been no post-operative hemorrhages nor post-tonsillectomy lung abscesses.

Preliminary rectal anaesthesia further simplifies the procedures necessary in bronchoscopy. By the adoption of oil-ether or Avertin as a pre-

liminary anaesthetic, we have diminished shock, eliminated all terrors of anaesthesia from patients, parents and ourselves. For instance, when the patient is a child (as he commonly is) the parent stays in the patient's room and sees him go to sleep. The child is not taken to the operating room until he is asleep, and so recalls nothing of the experiences in the operating room, returns to his room still asleep, and sleeps several hours after the operation. We are careful to wash out the colon by return flow irrigation as soon as the operative work is completed, and up to the time of publication we have seen no untoward effects in our own cases. We are fortified in our belief by the experience of Gwathmey who reports no bad effects in over 2,000 cases (personal communication).

Preliminary colonic anaesthesia saves fond parents much anguish; eliminates the "sobbing"

FIGURE V
Haslinger Head Rest.

respiration experienced when the patient is refractory, or is crowded under ether while struggling; makes the bronchoscopy easy of performance as it eliminates all struggling of the patient.

The return to consciousness of the patient after Avertin is somewhat prolonged, which is an advantage because it saves the patient from several hours of being conscious of a sore throat after tonsillectomy. The Avertin method is somewhat expensive in cost (both the product itself and the prolonged time before consciousness is gained during which time a nurse must be in constant attendance), but it is well worth it.

FIGURE VI
(L) laryngoscope, (C) intra-tracheal canula, (E) ether tube and (D) ether can used in the Foggy technique of intra-tracheal anesthesia.

Besides these advantages of operation and anaesthesia in tonsillectomy, we and our assistants, both doctors and nurses, become oriented to the "head on" position in doing operations about the throat, become accustomed to quickly doing a direct laryngoscopy and intubation by the direct method, all of which are fundamental to good bronchoscopy when the emergency arises which requires it. The direct bearing that these various techniques have on bronchoscopic experience is readily grasped by referring to the descriptions and illustrations published by the authorities mentioned. The author claims no originality in these methods, but has adapted several well-known ingenious methods to the end of training himself and his operating team in bronchoscopic technique.

The author takes pleasure in acknowledging his indebtedness to Dr. J. Ivimey Dowling, Chief of the Department of Eye, Ear, Nose and Throat Surgery, Memorial Hospital, Albany, N. Y., as well as the members of the medical, surgical nursing and executive staffs of the Memorial Hospital and Dispensary for their whole-hearted interest and cooperation in contributing to the successful establishment of this work.

CONCLUSIONS

1. A method is shown whereby bronchoscopic

orientation when once attained can be easily and routinely retained.

2. This method is advocated to supplement the fundamentally necessary preliminary bronchoscopic training on cadavers, phantoms and dogs which all students in bronchoscopy must go

through before they can conscientiously attempt this work.

3. The author's methods of co-relating and adapting several and sundry well-known surgical procedures to the end of developing bronchoscopic skill are described and illustrated.

A POSSIBLE ETIOLOGY OF RAYNAUD'S DISEASE

By ARTHUR F. KRAETZER, M.D., NEW YORK, N. Y.

IN the Journal of the American Medical Association for April 5, 1930, I published an account of a case of Raynaud's disease associated with chronic arsenical retention and cured by sodium thiosulphate. Since then several other cases have been studied and the results have been so striking and so uniform that it is impossible to avoid the temptation to speculate as to whether arsenic may not be the prime etiological factor in this curious condition,—for Raynaud's disease is curious, in fact, unique. Its symptoms, the successive appearance of local syncope of the fingers and toes on exposure to cold, local asphyxia with severe pain on warming, and finally the re-appearance of normal color, are due to spasm of peripheral arterioles. Whether this mal-function is due to excess sympathetic action or to local disturbance in the vascular wall itself, is perhaps not definitely decided, although evidence seems to favor the latter.

But in any event Raynaud's disease lacks the anatomical changes which we associate with chronic inflammation. It has none of the attributes of local infection, nor does it show any of the manifestations which we are in the habit of ascribing to distant focal infection. Its intrinsic characteristics suggest, and suggest with a high degree of plausibility, the effects of a drug. It is, in short, a "functional disease".

But it is impossible to conceive of a function going wrong of its own accord, out of pure moral perversity, as it were. There must be a cause and a cause different from those which we know to be the occasion of organic change. The suggestion of a "drug effect" is inescapable.

The case referred to above is briefly summarized as follows:

Case 1—C.M., woman aged 38 first seen October 7, 1929. From 1912 to 1926 worked in a green-house. It was part of her duties to spray Green Fly Spray on the plants every day. From 1926 on she did secretarial work. Every Spring, from 1922 on, an intensely pruritic rash would appear on the anterior surface of the wrists and would last about a month. Since 1928 she suffered from fatigue and noticed that her skin smelled like onions. The specific complaint started in February, 1929, at first limited to the terminal phalanges, soon involving the entire length of the fingers and toes. The symptoms were classical, syncope in the cold, blackish-purple, intensely painful asphyxia on warming, and finally normal color. The attacks were almost daily during the rest of the winter, cleared up in the Spring, and recurred in October, 1929, when she consulted me. She looked under-nourished, vaguely below par, tired and anxious. The skin of the face was tense and shiny, with numerous telangiectases, and had the waxy, almost atrophic, appearance of the arsenic eaters. Chronic blepharitis was present. The urine, collected for twenty-four hours after intravenous injection of 1 gram of sodium thiosulphate, showed 0.068 milligrams of arsenic per 100 grams of dried material. The blood chemistry showed a low sodium chloride, 437.7, sugar 103.2, urea-nitrogen 11.4, uric acid 1.98. Treatment consisted of 1 gram of sodium thiosulphate intravenously twice a week up to February 3, 1930. During the first week of treatment, the attacks were less frequent and almost lacking in pain, although the color changes were just as marked. Improvement kept on progressively. On October 19 and 25 there were attacks of local syncope, changing back to nor-

mal color without the intermediate phase of asphyxia. On February 3, 1930, she was discharged clinically cured. She went through the winter of 1931 without attacks and has remained free up to the time of writing, February, 1932.

Case 2—R. F., woman aged 33. Attacks started in the Fall of 1926 and consisted of the following series of manifestations in this order:

1. The ears turn dead white. The fingers turn pale but are not absolutely blanched.

2. The affected parts suddenly turn purplish red and there is a sense of swelling. Rubbing the parts causes itching. This stage lasts fifteen minutes to an hour. Severe neuralgic pain which may be intense, and which may persist after the skin returns to normal color.

Cold seems to precipitate the attacks, which occurred two or three times a day at first. Later on several months might elapse without an attack. During an attack there may be uncomfortable sensations in the face and tongue. Constriction and a dependent position increase the pain. She has done a great deal of painting. Early in the course of the disease she took arsenic and thought that the symptoms were aggravated. In 1929 she took up gardening and used a great deal of lead arsenate. In the Fall of the same year the attacks, temporarily less numerous, resumed their original frequency and severity. I first saw her in August, 1930.

Physical examination was negative except for chronic tonsillitis, chronic blepharitis and dermatographia. The urine was negative. Complete bloodcount was normal except for a mild anemia. The Wassermann was negative. The blood chemistry showed sugar 86.8, sodium chloride 441.8, urea nitrogen 13, uric acid, 3.12. The urine collected twenty-four hours after intravenous injection of sodium thiosulphate showed 0.093 milligrams of arsenic per 100 grams of dried material, and 0.3 milligrams of lead in 1000 c.c.

Treatment was started August 9, 1930, and consisted of 0.5 grams sodium thiosulphate twice a week. The following summary describes the course of the case:

August 14, 1930—No swelling or redness. Slight aching in toes and fingers.

August 18, 1930—Feels better generally.

August 21, 1930—Tingling and some pain, but no color change. Weather cooler.

August 25, 1930—No finger symptoms since August 23. Tongue slightly sore. Feels stronger.

August 29, 1930—Condition OK.

September 1, 1930—No symptoms except slight burning of tongue.

September 6, 1930—No symptoms.

September 11, 1930—No symptoms.

September 20, 1930—Fingers red and swollen on rising with slight aching pain lasting two

hours instead of the severe and longer lasting pain that usually occurred.

September 29, 1930—No symptoms.

October 1, 1930—Past twenty-four hours weather quite cool. This morning very slight swelling and redness of fingers of left hand alone, with very little pain.

October 6, 1930—No symptoms.

November 6, 1930—For past two weeks fingers have been numb on exposure to cold, but without pain, swelling or color change. This morning a characteristic attack, but mild and short-lived. Patient is convinced that there has been definite improvement.

December 4, 1930—No symptoms since November 6, in spite of exposure to severe cold.

January 5, 1931—Mild attack, the first in the past two months.

February 9, 1931—Free from symptoms.

On January 4, 1932, the patient had one slight attack but with this exception has passed through the present winter without trouble.

Case 3—H. E., woman aged 43. First seen October 19, 1931. Her complaint was that every winter for three years, especially while driving a car, one or two fingers would turn dead white and tingle severely. On warming they would return to normal color without an intermediate phase of asphyxia. She had suffered from pruritis for seventeen years. At some time in the past she had been given two courses of iron and arsenic injections. Two quantitative Marsh tests on the urine, after thiosulphate injection showed, one a trace of arsenic, the other 0.035 milligrams, per 100 grams of dried material. From October 19, 1931, to January 8, 1932, she was given two injections of thiosulphate a week. Improvement set in from the start. During this period, instead of the usual frequent attacks, there was but one and that merely the whitening of the tip of one finger on rising one cold morning. On January 8, 1932, she reported occasional slight tingling of fingers without color change while driving car in the cold, and was discharged clinically cured. Incidentally, the winter itch cleared up likewise.

Case 4—E. M., woman, aged 25. First seen February 11, 1931. There was a history of taking tonics. Complaint: For two years fatigue, anorexia and inability to stand the cold. Quite incidentally she mentioned the following: In March, 1930, just after coming in from outdoors, the terminal phalanges of the third and fourth fingers of the right hand turned dead white for a few minutes, and then a deep red for a few minutes, finally resuming their normal color. There was no unusual sensation.

The next attack occurred in the Summer of 1930 while swimming. The terminal and middle phalanges of the right middle finger turned

dead white, with a sharp line of demarcation at the base. This stage lasted about five minutes and was accompanied by a sense of numbness. The two phalanges then turned a deep purplish red with a sense of tingling and burning but no real pain. This stage lasted a few minutes and seemed to be brought to an end by vigorously shaking the hand.

Physical examination was negative except for the general appearance of fatigue and being vaguely below par. Poor peripheral circulation was indicated by the presence of marked livedo and acro-asphyxia. The urine collected twenty-four hours after intravenous thiosulphate showed no lead but 0.154 milligrams of arsenic per 100 grams dried material. She was able to take only two injections of thiosulphate, but took it regularly in capsule form five grains three times a day. On March 3, 1931, she reported that on stepping into a hot bath after a long walk in the cold, she noticed a tingling sensation in the soles with marked pallor. The color soon returned to normal without any intermediate stage of exaggeration. She said that after the month of thiosulphate by mouth she was feeling much stronger.

In March, 1932, she reports that she had no attacks in spite of going in swimming and being exposed to cold. The general condition is greatly improved.

The attacks in this case were of course too mild and too infrequent to derive any conclusions as to the effect of treatment upon them. It is, however, not without significance that in this patient's case, as in the rest, arsenic was found in the urine and the general health improved greatly under thiosulphate.

Case 5—A. M., male, aged 30. First seen April, 1921. His complaint was fatigue. In 1913 in South America he had a penile sore which, without any investigation by dark field or Wassermann, was treated with 3 injections of arsphenamine and 10 of mercury.

Examination, April, 1921, was negative except for coated tongue, blepharitis, a mild secondary anemia, and moderate acrocyanosis, the possible significance of which last named finding did not suggest itself to me. By way of doing a good job, I prescribed iron and arsenic, which he took for several weeks. From April, 1921, to February, 1932, he has been under careful observation for lues, but all findings, physical, blood and spinal fluid, have been negative.

Though not sick, he has never felt very well. In May, 1931, he complained of increased fatigue and a sense of tingling in the feet and head. On a cold day the terminal phalanx of the right forefinger turned dark purple and felt numb. The feet felt numb and were very sensitive to cold. Tobacco seemed to intensify the sense of tingling.

Intravenous thiosulphate was started May 7, 1931, but only a few injections were given. The urine showed 0.268 milligrams of arsenic per 100 grams of dried material. The following notes were taken:

May 11, 1931—The tingling has left the feet. It left the hands temporarily and then returned in lesser degree. Still present in left temporal region and tends to shift over scalp.

May 14, 1931—Tingling markedly diminished. May 18, 1931—No tingling. Violaceous color of face is less marged.

May 21, 1931—No tingling.

May 30, 1931—After prolonged swim, left index finger turned dead white for fifteen minutes and then returned to normal without asphyxia or paraesthesia. Patient was free from symptoms until January, 1932, when there was return of the tingling and sense of fatigue. After a hot bath the feet, especially the toes, would get scarlet. Syncope of the terminal phalanx of one finger occurred once on a cold day. All symptoms again responded promptly to sodium thiosulphate.

As in Case 4, the Raynaud symptoms were too mild and too infrequent to base any direct conclusions upon. The association with these mild symptoms, however, of severe paraesthesia, marked fatigue plus a large amount of arsenic in the urine, capped by the clearing up under thiosulphate, certainly suggest that all the symptoms can be grouped under a common etiological head. It is possible that in this case an element of peripheral neuritis was present.

Conclusions: Five cases of Raynaud's disease are reported, two severe, one moderate and two abortive. Arsenic was found in all of them. Under treatment with sodium thiosulphate, not only did the Raynaud symptoms clear up, but associated symptoms theoretically producible by arsenic, such as pruritus, paraesthesia and chronic fatigue, cleared up *pari passu*.

Comment: The idea expressed in this article is an hypothesis, not even a theory. The unfailing coincidence, however, of presence of arsenic plus cure on removing the arsenic, can hardly be ignored and is certainly worth further investigation, whether to prove or to disprove. Despite the undistributed middle term in the argument laid down, there is sufficient proved theoretical background to render the idea plausible.

Throne and Myers demonstrated arsenic in 30% of cases of eczema, which certainly is a sufficiently frequent disease. Of these cases a large proportion recovered under thiosulphate. What is more significant is the fact that they found arsenic retention in several other dermatoses and in many individuals who apparently had no symptoms whatever. In other words, they showed that widespread arsenic retention is a fact, the source of the arsenic being frequently

undemonstrable but doubtless in a large number of cases being the insecticides used so lavishly on fruit and vegetables. It only remains to ask what symptoms is arsenic capable of producing. Obviously, any symptom referable to the sympa-

thetic and vascular systems, for which it is a specific poison. Hypothetically, arsenic should be capable of causing Raynaud's disease. In the cases herein reported it has, I think, been demonstrated as the cause.

THALLIUM ACETATE, ITS TOXICITY AND DEPILATORY ACTION

By HERMAN GOODMAN, M.D., NEW YORK, N. Y.

History

THALLIUM was discovered by Crookes in March, 1861, by spectral analysis. He found a green band at 5350 angstrom units. He named the element thallium from the Greek 'thallos' meaning green and budding twig.¹

Clinical Use and Toxic Effects

Combemale² used 10 to 20 mgs. for night sweats in patients with tuberculosis. He noticed that the loss of hair was rapid and complete.

Richet³ associated chronic poisoning with thallium and muscular atrophy. According to Cushny's book of pharmaceutical therapy, p. 670, 9th Ed., 1928, Richet was the first to observe the depilating effect of thallium. (Obviously incorrect.)

Early Clinical Experiment

Bullard⁴ curiously used the name of Brooks throughout his article instead of Crookes as discoverer of thallium. He gives some historical notes on thallium, and describes a case in a physician 37 years of age who took thallium for experimental purposes. He took one half to one gram every second day for three or four doses and then after two months he took several doses more. Nothing happened after the first experiment, but three or four days after the second, he noticed numbness in his fingers and toes and was taken to the hospital where his case was diagnosed as multiple neuritis.

Mechanism of Action of Thallium

Dowling⁵ wrote that the remarkable action of thallium acetate in producing alopecia is so far as is known shared by no other substance. The exact mechanism of its depilatory action is not absolutely known, but certain established facts appear to show that this action is upon the sympathetic nervous supply of the follicles and not directly on the follicle or hair bulb itself. Endocrine glands are clearly concerned in the action of the drug. The postmortem examination of the animals which had undergone prolonged thallium feeds revealed in all cases changes of an atrophic

nature in the suprarenal glands, the thyroid and testes.

Truffi⁶ stated that thallium alopecia is directly due to the action of the salt on the hair forming process. A series of histologic examinations of the scalp of patients treated with thallium show evidence of epithelial degeneration of the hair follicles and sclerosis of the connective tissue.

Animal Experimentation

Schneider⁷ reported on the basis of two years of experimental work on the ingestion of thallium by rats, mice, rabbits, and dogs which he had bred. Rat poison—zelio paste—which is 2.8 per cent thallium, and zelio corn which is 2.1 per cent thallium was mixed with the food. Ill effects were noticed within from 16 hours to 4 weeks. Two weeks were needed for the loss of hair or alopecia. Examination of the rats and other animals showed degenerative changes in the central and peripheral nervous systems. There was a diffuse ganglionic disease. There was no damage done to any portion of the central nervous system. Schneider thinks that thallium acetate is very toxic. His opinion is that it is necessary to strictly limit its use. He reports that this thallium rat poison had been used by suicides and criminals with intent to kill.

Schamberg and Brown⁸ gave two 2½ kilo rabbits 10 doses of thallium acetate by mouth at 3-day intervals, the dose being 2 mg. per kilo body weight followed by 3 doses at 7-day intervals of 8 mg. per kilo weight. After the second dose of 8 mg. per kilo there was a rapid loss in weight and following the third dose the animals were in such poor condition that they were killed. No loss or loosening of their hair was observed. The adrenals, parathyroids, skin and hair were removed for analyses. Thallium could not be detected either as the iodide, chlorplatinate in the flame test, or by the bright line spectrum.

Rat poison in the form of thallium sulphate was tested by Ward⁹ on sheep. The dose was 25 mg. per kilo of weight. The animals died on the 8th day. Doses of 10 mg. per kilo of weight were so small that the sheep survived but a noticeable slipping of the wool took place from the 13th day.

The symptomatology of thallium poisoning among the sheep included clamping of the teeth, loss of appetite, general dejection, digestive disorders, muscular cramps in the hind legs, and coma. Death was due to respiratory failure.

Epilating Action of Thallium

Drummond¹⁰ stressed the point of some biological and also practical interest in the fact that epilation following thallium leaves a narrow strip of hair across the forehead (the "old Man's fringe") unaffected. It has been proved according to Drummond that this hair shows a greater resistance to external and internal irritation than other hair growths. The eyebrows likewise are unaffected. He asserts that thallium is highly toxic to adults and should not be given to them.

Feldon¹¹ reviewed the statements and warnings regarding the intoxication from the use of thallium acetate in the treatment of ringworm of the scalp of children. He noted the peculiar fact that thallium cannot be used in the same dosage after the development of puberty without greater danger than in children. There is a marked increase in the toxicity which is probably due to the changed function of the endocrine-sympathetic system after maturity. He gives a report of two children, one a girl aged 15 who was completely infantile physically, size of child of 3 and only 35 lbs. in weight. Second child was a boy, a cretin, also infantile, age 19, but of the height of a child of 5 or 6 years. These two children showed only a slight epilatory effect which was insufficient to remove all of the infected hairs. This was undoubtedly due to the marked disproportionment between age and body weight. The development of the endocrine organs possibly is parallel to the age and not to the body weight and if so the dosage made according to body weight does not correspond to the size of the endocrine organs.

Toxic Action of Thallium

Buschke and Langer¹² described several cases of poisoning with suicidal intent from thallium in a rat poison sold freely in Vienna without a poison label. Characteristic symptoms in these cases consisted of pain in the joints, swelling of the feet and legs, colic, vomiting, sleeplessness, mental confusion, and a striking loss of hair from the head and body about three weeks after the administration of the poison. Too rapid administrations of thallium for therapeutic purposes has also been attended by toxic manifestations. The authors stated that a period of two to three months should elapse between the first and second administration of thallium. They write that it is possible to demonstrate thallium in the blood and urine within four weeks after the administration of a large dose. They mention that thallium is used in industry in the making of colors, window

glass, and luminous paints, and that poisoning is possible from occupational contacts.

Greving and Gagel¹³ observed an attempted suicide who had spread half a tube of zelio paste on bread and swallowed it. Patient became ill two days later with pain and weakness in the lower extremities, albuminuria, loss of hair on the 11th day. She was ill for several months suffering from peripheral neuritis, loss of appetite, pain in the chest, emaciation, depression, and amenorrhea.

Teleky¹⁴ described a number of cases of industrial thallium poisoning occurring in workers in a factory for the recovery of thallium. They had inhaled a powder (dust) of metallic thallium that is composed of thallium oxide and thallium sulphate. Besides alopecia, signs of poisoning manifested themselves in fatigue, anorexia, pains in the joints and lower extremities, albuminuria in nearly all cases, and a definite lymphocytosis of over 40%. In one case there occurred after a month, heart burn and redness of the hair. Four months after beginning of regular work with thallium one patient showed a diminution of vision that progressed rapidly.

Cosmetic Depilation with Thallium

Sabouraud¹⁵ as far back as 1897 suggested the use of thallium acetate as a depilatory. In 1912 he advocated the use of thallium acetate in 1% concentration once a day in a very small quantity and over a very small surface.

Paris Letter¹⁶ stated that Sabouraud had used thallium acetate in his service at the Hospital St. Louis to bring about a complete removal of the hair in children affected with tinea. Paris Letter uses about the same material as Sabouraud published under the heading "Sur les Depilatoires" in Clinique Paris (to be quoted).

Sabouraud¹⁷ reported that thallium acetate by ingestion is capable of causing loss of hair in 15 days. It is not a harmless remedy and is to be used only under proper direction. Sabouraud has shown that a paste of thallium acetate of 1 or 2% concentration applied every night to the lip and chin can within 6 or 8 months cause a reduction of the mustache or a commencing beard. The medicament should be used with care for one sees a number of cases of intoxication. It is essential to write the particulars of the dosage on the prescription. These are: Each evening treat only a small area of the total area of excess hair to be treated. The ointment must be applied by massage and the hands must be washed immediately thereafter with soap. The results will then be attended with little danger. All the accidents observed were among young girls who used the medicament in three times the dose advised. Grave toxic effects have been seen as temporary loss of all hair, temporary paralysis of the extremities, and nerve toxicity of several weeks' duration. Sabouraud was convinced that only those patients

who did not follow his advice were the subjects of these accidents.

Abramowitz¹⁸ stated that a 10% thallium cream has been used in hypertrichosis and scycosis, but an alopecia of the scalp frequently resulted with or without epilation of the area treated. A 10% cream was considered too toxic. Ionization has been utilized with a 2% solution of thallium acetate. It has been reported partially successful in hypertrichosis.

Koremu—A Commercial Thallium Depilatory

Lansbury¹⁹ reported that a patient used cream on upper lip and under the chin. Two weeks after use of the cream she noticed pain in the chest, cramps, nausea, vomiting, and constipation; papuloid purpuric spots; hair of scalp was loose and easily pulled out; the eyebrows and eyelashes were not involved, but the scalp was completely bald except around the ears. (Name of cream not mentioned, but Editor notes that it was Koremu.)

The J.A.M.A. noted²⁰ that Koremu Cream had been on the market some time. At first, it was under the trade name "Kora M. Lublin," and more recently as "Koremu, Inc.," both of New York City. According to the advertising, Koremu is "Guaranteed to devitalize superfluous hair roots on face or any part of the body."

At the request of the Bureau of Investigation, the A.M.A. Chemical Laboratory was asked to make an analysis of the Cream. The Laboratory report follows:

Laboratory Report

"an original jar of Koremu Cream; (Koremu Inc., 11 West 42nd Street, N. Y. C., price \$10.00) was submitted to the A.M.A. Chemical Laboratory for examination. The label on the jar bore the following statements: 'Koremu Cream devitalizes superfluous hair roots. . . Will induce baldness wherever applied when used as directed.' The jar contained 69.8 Gm. (approximately 2½ ounces) of a light yellow ointment, strongly perfumed. Qualitative tests indicated the presence of thallium, zinc, acetate, petrolatum, traces of chloride and of saponifiable matter. Heavy metals (such as mercury, lead, arsenic and cadmium), sulphides, iodides, borates and salicylates were not found. Quantitative determinations yielded the following:

Thallium (TI)	5.57 per cent
Zinc (ZN)	7.68 per cent

This may be calculated to:

Thallium Acetate	7.18 per cent
Zinc Oxide	9.56 per cent

"From the foregoing, it is concluded that the product examined consists essentially of an oint-

ment having a petroatum base, in which are incorporated approximately 7 per cent thallium acetate and 9.5 per cent zinc oxide.

"In view of the chemists' report, it is again worth calling attention to the facts developed by Dr. Sabouraud. On the basis of long experience he declares that any ointment containing more than 1 per cent of thallium acetate is dangerous. Koremu was found to contain over 7 per cent! Sabouraud insisted that no larger amount of his one per cent ointment than that equal to two kernels of wheat should be used at a time; no limit is given to the amount of Koremu that should be applied! As the whole trend of the Koremu advertising emphasizes that the stuff is harmless, it is to be expected that women purchasing this product will apply it with the same easy abandon that they use in applying face creams and vanishing creams. It is hard to believe that Kora M. Lublin, who seems to be behind this product, realizes the dangerous properties of the preparation she markets. It is kinder to assume that ignorance, rather than a callous disregard for public safety, prompts the sale of Koremu!

"There is one other point that seems to deserve some attention—that is, the wide discrepancy between the commercial value of Koremu and its selling price. The approximate cost of the ingredients that go into the jar of Koremu, selling at \$10.00, is less than thirty-five cents! This allows 27 cents for the thallium acetate, 1 cent for the zinc oxide, and 4 cents for the petrolatum. However Koremu's assault on the public's pocket-book becomes a minor indictment; the major objection is its menace to the public health."

For comparison with the formula given above for Koremu we give the formula for epilating cream as used by Sabouraud taken from page 437 of his book "Entretiens Dermatologiques":

Acetate of Thallium	0.3
Zinc Oxide	2.5
Vaseline	20.0
Lanoline	
Rose Water	aa 5.0

Further Clinical Reports

Duncan and Crosby²¹ reported a case of thallium poisoning from prolonged use of Koremu Cream. Patient had used Koremu Cream nightly for the preceding 5 months beginning its use 2 weeks before appearance of the first symptoms. A quantity sufficient only to cover the upper lip and chin had been used on each occasion. At each application the cream was well rubbed in. At the time of examination hair was distributed normally over the body with exception of the face where the growth was more profuse than is normal, and this hair was firmly imbedded.

Greenbaum²² reported a case of thallium poison-

ing. Patient began use of Koremlu Cream on January 15th. She was seen by Greenbaum on April 8th. She had used the Koremlu for about two months before she first noticed the alopecia. At the time of examination the loss of hair on the scalp was incomplete but marked. The drug buyer of the department store stated that this had been the only complaint in 400 sales. Greenbaum noticed that the excess hair to which the cream had been applied on the upper lip and cheek still persisted.

Schamberg²³ reported that he had seen one case of Koremlu poisoning on April 12th, and one of his assistants had seen a case, and an acquaintance of his had seen a case. In Schamberg's patient there was loss of seven-eighths of the hair on the scalp which had been pronounced for the past three weeks, although it had existed for some weeks previous. The patient had applied Koremlu to the axilla. Hair was still persistent. She began to use the Cream in April or May of 1930 and had applied it every night until she had had a nervous breakdown. She had resumed the use of Koremlu two weeks in February and showed loss of scalp hair, had neuritis, noticed general weakness, loss of weight, and was highly nervous.

Short²⁴ reported a case of neuritis from thallium acetate. The hair of the scalp was thin, although the excess hair of the face and abdomen persisted. Koremlu had been used for some time, since October, 1930, regularly every day. The toxic symptoms had appeared about two months after she began its use. She was using her second jar of Koremlu Cream. Patient noticed pains in February, 1931, and loss of hair on April 1st. She had used several jars of Koremlu Cream.

Hair Growing Properties of Thallium

Cooper and Engman²⁵ reported on the stimulating effect of small doses of thallium acetate on the rate of growth of hair in the rat. Single doses of 0.004 and 0.006 grams of thallium acetate per kilo body weight dissolved in distilled water injected intra-peritoneally into white rats produced 18% increase in the rate of hair growth. Doses of 0.002 grams per kilo weight were too small to produce any effect on the rate of hair growth.

Absorption of Thallium

Dixon²⁶ was definite that the symptoms of toxicity due to thallium depend on absorption. Thallium rubbed into the skin has no local action. Thallium is readily absorbed into the skin with alcohol or oil. It causes alopecia only after absorption. The effect is mainly on the autonomic motor system which is rendered more sensitive. However, this is more marked on the sympathetic portion, so that electric stimulation of the nerves produces an exaggerated response, even though the stimuli are below the normal response level.

Pathology of Thallium Toxicity

The summary from Prokoptchouk, Bachkievitch, and Chamchine²⁷ is given herewith:

1. The thallium preparations, by their influence on the vegetative nervous system, produce a series of changes on the latter, which in their turn act on the appendages of the skin, particularly on the hairs, causing a whole line of plethoric disturbances to the vessels of the hair bulbs, now in the shape of phenomena of an inflammatory character, with infiltration of round-cells; now again as foci of agglomerated cells, in the shape of furuncles.

2. Like all other salts of the heavy metals, such as mercury, bismuth and lead, thallium can produce a great many serious disturbances in the organism. These disturbances are as follows:

(a) In the skin, besides falling of the hair, folliculitis and a toxic eruption similar to the ones produced by mercury or bismuth, and of a hemorrhagic character as petechiae and ecchymoses.

(b) In the mucous membrane of the mouth, besides gingivitis, glossitis and stomatitis—even in its ulcerative form—the phenomena of an angina thalli. One also encounters cases of herpetic eruption, rhagades and sanguineous spots on the lips; and it should be noted that thallium can cause diarrheas and sharp pains in the stomach.

(c) The mucous linings of the stomach and intestines show a picture of either stippled or completely fused hemorrhages, besides one of either desquamative or ulcerative colitis.

(d) In the liver, we notice, besides hemorrhages, thallium necroses and nephritis.

(e) In the liver and spleen, the phenomena are mostly of a vascular character. Besides rapid palpitations of the heart, we sometimes find paracardiac pains, which must probably be explained as due to influences from the vegetative nervous system.

(f) Acting on the vegetative nervous system, the thallium preparations can thus, through the latter, affect also the other branches of the nervous system, thereby producing those phenomena of quickly passing, epileptiform psychosis termed chorea. They can also act directly, and produce such phenomena as, for instance, thallium polyneuritis, disturbances of the blood vessels, including the peripheric blood vessels of the brain, and cerebral hemorrhages.

(g) At the same time as the polyneuritic phenomena, one notices pains in the articulations, astralgias, accompanied by swelling, tenderness and crackings.

(h) The disturbances thus described can be accompanied by pyrexia, and can cause the patient to become greatly emaciated and very weak, by changing the metabolism in the direction of a disaggregation of the blood-corpuscles already from

the first dose of the thallium. They can also express themselves by interfering with the process of assimilation of the ingested food, a complication occurring especially in connection with serious disturbances in the intestine.

Retrolbulbar Neuritis

Loss of sight as a result of thallium poisoning had been observed by Teleky¹⁴ in the industrial field. Mahoney²⁸ reported retrolbulbar neuritis due to thallium poisoning from depilatory cream in three patients. The cause of the toxic optic neuritides was not suspected at first. Each of the patients reported gave a history of the use of the proprietary depilatory, Koremlu Cream.

The three patients were admitted to the neuro-surgical clinic as "intracranial tumor suspects," and were found to have an advancing retrolbulbar neuritis. Their failing vision was checked, and improved by discontinuing the employment of the thallium depilatory.

Clinical Experiences: Koremlu

Miss G., referred to me for an eruption of the left side of the chin considered as impetigo contagiosa. The chin lesions on examination were vesicles, remains of vesicles on a red edematous base without any of the crusting suggestive of impetigo. The clinical diagnosis of herpes simplex was made. The patient volunteered the information that she had had several appearances of the same or similar eruptions about the same site. She had one tooth which was giving her trouble, and it was thought that the dentist should examine for foci of infection.

The clinical examination disclosed a very scaly scalp with loss of hair back from the forehead over the eyebrows. This type of loss of hair recalled the pattern baldness of post puberty males. The young woman said she was past 21, but would not give her accurate age. She was about 30. She was single. It was not feasible to attempt to learn about sexual habits or tendencies. Soothing application was ordered for the herpes, and glycerite of starch for the scalp to remove the scales.

On the second visit, the scalp was much cleaner. The tendency to pattern baldness was evident. The herpetic lesions had regressed. The hemoglobin was about 60 per cent. The patient was markedly nervous, and although she knew better had taken part in a discussion on religion with her superior at the office putting her "job" in jeopardy. There was slight prominence to the eyes and widened ocular angle but no exophthalmus. The region of the thyroid was prominent but the neck was thin and scrawny.

The hair of the face and sides of the neck showed very fine lanugo hairs in small number. The upper lip (mustache) region was clear. There

was no evidence that a depilatory was needed or had been used. The patient asked informally for suggestions as to the use of a depilatory, and I thought she asked for a friend or relative. I was surprised to learn that she wanted this information for herself, and that further, she had been using Koremlu. She claimed that she had wonderful results in so far as the hair on the face was concerned, but admitted that in fact, the hair there had never been conspicuous, and that she was supersensitive with little cause. She had used one jar over a period of eight months, and felt very satisfied.

The recurrent herpes, and the loss of hair with the use of the thallium acetate as a depilatory, seemed to offer an example of toxic reaction to the metal. It was suggested to the patient, who said she would no longer consider using the Koremlu.

Therapeutic Thallium for Ringworm

A number of children were examined at one time or another who had received the thallium acetate properly weighed for epilation of the scalp preliminary to antiseptic treatment for tinea capitis. One child was very ill with symptoms of intestinal upset, articular inflammation, marked pains in the chest, inability to hold food, loss of weight, and general debility. This patient required hospitalization.

The epilation of the scalp following thallium acetate was observed. The complete epilation of the pre-puberty group, and the partial epilation of the post-puberty group led me to frame the concept of nerve baldness. It appeared that thallium acetate probably acted through the sympathetic nervous system. The loss of hair was more nearly complete prior to puberty than after puberty was established. The control of the scalp hair of the entire scalp was under the sympathetic until puberty, and that the central nervous system then had a share. The recorded observation of Celsus made almost 2,000 years ago that persons with alopecia areata of the ophiasis type (periphery of the scalp) offered a poor prognosis compared to those with loss of hair in the center of the scalp was considered in this concept. Then, too, it is known that the borders of the scalp hair are more resistant to dye. Further, when a man loses his hair from the center of the scalp in the pattern of the Calvities Hippocratica, the hair at the periphery grows more rapidly so that the bald headed person must have less and less hair cut more and more often.

One of my assistants began the use of thallium acetate by ionization for the treatment of excess hair of the chin and mustache region. He did not finish the experiment because of the reports of toxic action by this method of administering the drug.

Animal Experiments

The reports that pilocarpine hydrochloride had the effect of growing hair when injected locally, given by mouth, or used as a scalp wash seemed to indicate that the action on the sympathetic nervous system of the pilocarpine and the thallium might be antagonistic. With this in view, a series of experiments were made:

Three guinea pigs of about the same weight and age were selected. Pig one was given 8 milligrams per kilo of weight of thallium acetate dissolved in water forcibly by mouth. Pig two received 8 milligrams of thallium acetate and in addition one-twelfth of a grain of pilocarpine hydrochloride by mouth. Pig three received one-twelfth of a grain of pilocarpine hydrochloride alone. From theoretical considerations, pig one should have succumbed; pig two should have survived; and pig three should have been unaffected. Strange as it may seem, this was what actually occurred. Pig one died within eight hours after oral administration, and the other two pigs lived. The post mortem examination was very brief—abdominal section. It was noted that the stomach was markedly enlarged with definite constrictions at the two orifices—the esophageal and pyloric. These constrictions were so definite that removal of the stomach by section resulted in the removal of a stomach sac which did not leak any contents at either aperture. The stomach was opened, found to contain a large quantity of yellowish fluid. The mucosa was thinned.

The oral administration did not seem to be certain. The next three guinea pigs were given the drugs in the same dosage by intraperitoneal injection. The pig which received thallium acetate alone died within the eight-hour period. The other pigs survived. The post mortems were more complete—the brain case was opened, and the softening of the cerebral tissue noted; the chambers of the eye were engorged; the heart muscle was congested with pronounced hyperemia; the lungs showed dilatation of the wall the blood vessels, and extravasation of blood into the edematous lung tissue; the intestinal walls showed areas of denuded mucosa, and extravasation of blood into the coats; the liver, spleen and kidney showed the same picture: edema, widening of the blood vessels; and extravasation into the tissue of blood elements. The pathologic pictures were monotonous—and similar to those found by others.

The surprising repetition of the action of the pilocarpine hydrochloride in preventing the action of the thallium acetate immediately must be commented upon, but further experiments along the same lines have not given the same results. In the most recent experiments, the pigs receiving thallium acetate and pilocarpine hydrochloride died. The pathological findings were the same for both sets of pigs.

The main purpose of the experiments was to attempt to find if there was any antagonistic action between the two drugs. Our final conclusion is that none was really demonstrated by our work.

The pigs died too soon after the administration of the lethal dose of thallium acetate to expect any action on the hair. There was no effect noted. It is our opinion, that experimentation on the rate of growth of hair in the rodents is very difficult of control. The normal rate of regrowth after any procedure is very rapid. Local application of thallium paste to the skin of these animals must be guarded as it is impossible to prevent the animal from licking the paste and getting it into the system by this means.

Summary

Thallium acetate and other salts of thallium have been recognized as toxic to man and animals from the time of the discovery of the element. Its use in night sweats disclosed the epilating action. Sabouraud attempted to make use of this action in the cosmetic removal of unwanted hair but found many untoward reactions and has guarded his prescriptions for this purpose. Many attempts to explain the epilating action of thallium have been made, but there is no agreement as to the mode of action. It seems accepted that the metal has an effect on the sympathetic nervous system, although a local action on the hair forming process is claimed. The toxic action of thallium salts on animals has been used in poison potions for undesirable animals. Rat poison containing thallium has been used in criminal attempts to kill and by those desiring to commit suicide.

Within the past two decades, there has been a revival of the therapeutic action of epilation through thallium. Thousands of children have received the drug for the preliminary epilation of the scalp hairs to afford treatment of infestation with tinea organisms. Toxic effects due to the drug in proper dosage, and deaths from the inadvertent use of large doses because of poor mathematics or misunderstanding of orders have been reported. It is true that thallium is falling into disfavor, that is, in so far as its use as therapeutic epilatory is concerned for scalp hairs.

On the other hand, commercially minded concerns have taken advantage of the work of Sabouraud, and have placed before the public various thallium creams for the epilation of unwanted hair of the face and arms. Women are tremendously sensitive in our day and age to any hairiness. The sales of one American product which promised miracles at a high price were very large. Many women used this paste. Throughout the country, undiagnosed instances of thallium intoxication were treated for many conditions, but the role of thallium was soon uncovered. The physicians throughout the country have reported

such unmasked thallium acetate poisoning. The American Medical Association and other agencies guarding the health of a community (which all too often does not want the kind of supervision or which disregards it) have reported on thallium depilatories. In the City of New York, no official action regarding the sale of this type of product has been taken. Any woman with the price can purchase a thallium depilatory and use it.

What attitude the individual physician and health officer takes is determined by considerations beyond the purpose of this paper.

My clinical experience and what few experiments I have done follow that of others in this field: thallium acetate as a depilatory does offer the opportunity of toxic action of persons using it whether for cosmetic effect (unwanted hair) or therapeutic action preliminary to antiseptic treat-

ment of infested follicles with ringworm or favus. Pilocarpine hydrochloride does not prevent the lethal action of a lethal dose of thallium acetate administered intraperitoneally into guinea pigs.

It is our opinion, also, that many of the toxic results obtained from the external applications of thallium paste for the epilation of hairs of the upper lip or chin follow inadvertant oral administration. The application of the paste to the upper lip can easily lead to absorption by mouth. The very intimate contact of the upper lip and food or drink would permit of such absorption. The intermediate pillow case could also lead to such oral administration. The thallium acetate left on the massage fingers could easily be transferred to food eaten from the hand. Sabouraud recognizes this for he advises careful washing of the hands after the application is made.

GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Graduate Fortnights of the New York Academy of Medicine are of great importance to physicians and through them to the public. The Fortnights are contributions of the Academy to medical education and public health. They are free to all physicians and are patronized to the full capacity of the rooms in which they have been conducted.
Each year the Fortnight is on a subject of

general interest to all practitioners of medicine and workers in public health. The subjects of the Fortnights have been:
1928.....Old Age
1929.....Functional and Nervous Problems
1930.....Acute Bacterial Infections
1931.....Circulatory Disorders
1932.....Tumors

This year's Graduate Fortnight—the fifth—was held during the two weeks beginning October 17, 1932. It had the most extensive program and was the best attended of all, for physicians had anticipated it with keen expectation, based on the practical value of the four preceding Fortnights. Like those of previous years, this present Fortnight comprised four main features:

1. Afternoon clinics and demonstrations in hospitals.
2. Demonstrations of fresh pathological specimens in the Academy building during the early part of the evenings.
3. Evening lectures in the large assembly hall of the Academy.
4. Exhibits open all day and evening for three weeks.

The attendance was phenomenal. About eight hundred physicians secured tickets for the afternoon clinics, those on record coming from the following sections:

New York City.....	566
New Jersey.....	125
Up-State New York.....	37
Connecticut.....	12
Pennsylvania.....	7
Ohio.....	7
Sixteen other States.....	33

The attendance at the evening lectures varied from 1,500 to 500, with an average of over 900. The demonstrators of fresh pathological specimens were surrounded with eager crowds of doc-

tors, and were forced to repeat their lectures over and over.

The exhibits had to be seen to be comprehended. They filled practically all the available space of three floors of the Academy building. They consisted of preserved pathological specimens, photographs—many in life size—x-rays, charts, and statistical tables. One hundred and ten exhibitors were listed on the program, and the first estimate was that three thousand separate items would be shown, but the total was probably over five thousand.

While all forms of tumors were shown, the exhibits emphasized *cancers*, in accordance with the modern conception of the possible degeneration or development of almost any tumor into cancer.

Space did not permit extensive demonstrations of methods of cancer research but a striking series of photographs showed abnormalities of elks' antlers resulting from injuries during their growth. It is a noteworthy fact that a microscopic section of a growing antler bears a striking resemblance to that of sarcoma of a human bone. While this is now only a bit of scientific information, it may possibly turn out to be a milestone on the way to the ultimate solution of the cancer problem.

While no individual visiting doctor could assimilate all the information available at the Fortnight, he could yet get a comprehensive picture of the vast field of tumors; and when he returned to his practice, he would visualize the probable course of development of the conditions which he observes in a patient and would know where to go to get further light.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Third District Branch Meeting: This Journal of November 1, 1907 contains the following account of the first annual meeting of the Third District Branch of the Medical Society of the State of New York, which was held in Albany on October 22, 1907:

"Those intrusted with the arrangement of the program had made an excellent division of the day, the morning hours being devoted to clinics, the afternoon to reading of scientific papers. During the midday recess an excellent luncheon was served at the Albany Hospital, the members of the Branch being the guests of the Board of Governors. The long corridor in the centre of the building upstairs made a very attractive luncheon room, and the trained nurses in caps and uniform kept every one well supplied with the many delicacies prepared by the excellent chef of the Hospital. Such reunions are particularly enjoyable, as men renew acquaintance with those whom

they knew in hospital or college, and lay the foundation for new friendships.

"At the meeting of the Delegates, amendments were proposed to make the election of officers and selection of place of meeting the duty of the general body; in other words, to do away with the delegate system in the Branch. These lie over for a year.

"In the evening about fifty availed themselves of the kind offer of the managers of the Hotel Ten Eyck, who reserved the front dining-room for the exclusive use of the members and served an excellent informal table d'hôte dinner from 6 to 8 P.M. After dinner some members attended the theatre, while others took the evening trains home, thoroughly satisfied that the first meeting of the Third District Branch had been a great success.

"Ten clinics in five institutions were listed for the morning session, and eleven papers for the afternoon."

MEDICAL PROGRESS

A New Treatment for Chronic Arthritis of the Hip: Forage of the Femoral Epiphysis.—For cases in which the shock of surgical intervention would be excessive, Jacques Graber-Duvernay points out in the *Journal de médecine de Lyon* of September 5, 1932, the good effects of thermal treatment in the form of forage of the epiphysis of the femur, a method devised by Louis Duvernay in the last years of his life. At the outset the center of the head of the femur must be found radiographically or fluoroscopically. Then under local novocain anesthesia an incision is made, 10 or 12 cm. long, starting from the upper margin of the great trochanter and descending parallel to the axis of the limb. The perforator must penetrate the epiphysis at a point just 1 cm. below the subtrochanteric crest, and halfway between the anterior and posterior surfaces. The important point in this is that it enables the operator to appreciate adequately the thickness of the bone at this level, holding it between the thumb and index finger. At this moment an assistant must without fail hold the foot of the patient to prevent him from changing the position of the limb. The only instrument necessary is a gimlet, a joiner's auger, 6 mm. in diameter and 12 to 18 cm. long. With the imprint of an iodized thread the center of the head of the femur and the point of implantation of the gimlet are joined by a line, which thus gives the angle of inclination of the neck of the femur. The center of the head having been reached by the gimlet, the forage is carried out without difficulty. It is much easier than in the case of fracture of the neck, since there is no solution of continuity between the neck and the head of the femur. In some cases a peg of dead bone, 5 to 7 cm. long and 5 mm. in diameter, has been introduced into the channel that has been opened; this serves as a means of orientation for controlling the direction of the forage in the indispensable postoperative radiogram. The same can be accomplished by injection of lipiodol through the orifice of the trepanation. There is no postoperative shock, and no need of a plaster cast. The remarkable fact observed is that the pain of the chronic arthritis ceases almost immediately in the days immediately following operation, and the patients can be discharged in 15 to 20 days. This result is explained on the ground that forage lowers the blood pressure on the side where it is carried out. All traumatism causes hyperemia, that is, vasodilatation. It appears that at the end of 3 weeks vasomotor equilibrium is reestablished and a vasoconstriction occurs. In brief, forage accomplishes its results by establishing a new circulatory equilibrium at the level of the head of

the femur, which in turn produces an arrest of the evolution of the pathologic process. The results in 10 cases which the author reports indicate that the new equilibrium will be maintained.

Attempts at Surgical Treatment of Essential Arterial Hypertension.—On the basis of a form of procedure proposed by Pende, Gino Pieri says that he began in April, 1927, to perform resection of the splanchnic nerve in cases of gastric atony that had proved refractory to other forms of treatment. In 4 of these cases he made a point of studying the effect of the operation upon the blood pressure, which was normal or subnormal in all the subjects. The greater splanchnic on the right side was resected in all, and in one case both right splanchnics. In every case there was a more or less marked fall of blood pressure; in one case the lowered pressure has persisted for 3 years. On the basis of these results, Pieri carried out a splanchnicotomy in a case of essential hypertension in a man of 67 (maximal tension, Pachon 200, Riva Rocci 185) who had suffered with symptoms for 14 years, although the cardiovascular-renal apparatus appeared to be normal. Resection of both left splanchnics at once caused a fall of blood pressure (Pachon 165, Riva Rocci 155) which has been maintained for 2 years; the subjective symptoms were greatly improved, though not entirely cured, reappearing at intervals of months, upon occasions of violent emotion. This left-sided resection was carried out on the basis of the current opinion that the left splanchnic supplies both suprarenals. The technique was the resection of the thoracic portion of the greater and lesser splanchnics by the transmediastinal route, and the operation was perfectly tolerated. The objection that it is an especially grave procedure has no basis in fact, provided the correct technique is employed. With a view to a comparison of results, Pieri performed a unilateral (left) adrenalectomy in another patient suffering with hypertension (maximal tension 230, by both systems). The good effect upon blood pressure was nil, after the first immediate drop; on the contrary, the tension arose, and 22 months later was 280 Pachon. Clinically, however, the patient showed considerable improvement, with a diminished sense of thoracic oppression and decrease of tachycardia, persisting for 2 years notwithstanding hard labor. In another case operated on by an assistant, in which there was a complicating endoarteritis obliterans, the results of adrenalectomy were similar, the blood pressure rising from 250 Pachon to 270, as recorded 10 months later. It is thus impossible to draw any certain conclusions as to the relative

value of these surgical procedures, but in a general way the results of resection of the splanchnic nerves would appear to be more encouraging. Pieri interprets this as due rather to the vasodilator influence exerted upon the vast territory of the visceral circulation than to the absent or diminished stimulation of the suprarenals.—*Riforma medica*, July 30, 1932.

Hysteria, Trauma, or Epilepsy—Eugen Körner, writing in the *Deutsche medizinische Wochenschrift* of September 2, 1932, describes the perplexing case of a man of 30 who stated that, always previously healthy, he had begun, some 6 or 7 years before observation, and while engaged as a riveter, to suffer several times a year with boring pains in his temples, which rendered him unconscious for $\frac{1}{4}$ -1 hour, and were followed by violent headache and weakness. The first examining physician made a diagnosis of severe nervous exhaustion and hysterical seizures, with no evidence of occupational trauma. Körner himself had an opportunity to witness several of these attacks, and noted their resemblance to epilepsy. Roentgen examination of the skull revealed a markedly undulating course of the floor of the anterior cranial fossa and of the skullcap, and an uneven thickness of the bones; the sutures were for the most part ossified and unrecognizable. These findings at once excluded hysteria, but strengthened the impression of epilepsy. The spotted and wavy marking of the skullcap was a picture of bone atrophy, due to the increased pressure of the impressiones digitatae, and constituted a clear proof of an augmented internal pressure within the skull, related in some way to the attacks. The characteristic marks of craniostenosis, that is, of premature ossification, were recognized. The fact of a fall from a height of 4-5 meters in 1924, not previously revealed by the patient, now came to light. The circumstance that although he had lost consciousness he had not later visited a physician, and his failure to mention the incident, suggested that the fall might itself have been due to one of the attacks, and hence was not regarded by the patient as an exceptional experience. Though this theory could not be proved, the roentgen picture was decisive for a pressure atrophy of the cranial bones, clearly attributable to a high grade craniostenosis dating from an early period of development. Pressure due to trauma would have forced the sutures into visibility to some extent at least. The case, although running an epileptiform course, must therefore be regarded as neither a traumatic nor a genuine epilepsy, but as the result of an early developmental disturbance.

The Heart Rate During Sleep in Graves' Disease.—Ernst P. Boas recalls the fact that a persistently rapid heart rate is one of the most

characteristic features of Graves' disease. It is caused chiefly by one or all of the following factors: The increased consumption of oxygen by the tissues which necessitates an increased minute-volume flow of blood to which the acceleration of the pulse beats contributes; the action of the altered thyroid secretion on the heart itself; the action of the altered thyroid secretion on the sympathetic nervous system leading to a neurogenic tachycardia superimposed on the basic acceleration determined by the first two factors. The presence of an unexplained sinus tachycardia properly suggests the existence of Graves' disease, yet in many instances such a rapid heart rate is due solely to neurogenic or psychogenic factors. Neurogenic sinus tachycardia is caused only by a disturbance of the nervous regulation of the heart which interferes with the usual well regulated reflex adaptation of cardiac function to the needs of the body. The determination of the basal metabolism is useful in distinguishing these two types of tachycardia, but there is also another method of differentiating neurogenic from thyrotoxic tachycardia which is by determining the minimum heart rate during sleep, as this is the best measure of the intrinsic chronotropism of the heart. The author has studied the heart rate during sleep of patients with Graves' disease and of those with neurogenic sinus tachycardia by means of the cardiograph. He found that in Graves' disease there is little reduction of the heart rate during sleep, the minimum sleeping rate being on the average over 30 beats higher than that of normal people. In neurogenic sinus tachycardia the heart rate shows a marked reduction during sleep, but does not quite attain the low level observed in normal subjects. Therefore the measurement of the heart rate during sleep is of diagnostic value in distinguishing thyrotoxic from neurogenic tachycardia and also serves as a rough check on the reliability of the basal metabolic determination.—*The American Heart Journal*, October, 1932.

Anorexia Nervosa.—Fred Elsworth Clow reviews the literature and reports two cases of anorexia nervosa. Patients with this condition are what is known as "mental anorexics." They are usually young women, who, without having any physical lesions, by the association of various troubles, all having a psychic origin, have lost a quarter, a third, or a half of their weight. Sir William Gull, who first described the condition in 1874, as well as Osler, considered the disease a manifestation of hysteria. Within recent years investigations have been made to establish a metabolic or endocrine etiology, but there is still considerable divergence of opinion. Osler says that the emaciation with marked retraction of the abdomen, sunken eyes and dilated pupils, is comparable only with that of cancer of the esophagus. There is, however, no sign of or-

ganic affection. The patients develop an aversion to food, there is peristaltic unrest, marked constipation, occasionally diarrhea, pallor, a high grade of anemia, slow weak pulse, and scanty urine. Mentally there are irritability, restlessness, sleeplessness, and obstinacy with slow speech. In time delirium with a slight fever may develop and the exhausted patient may succumb to the disease or to bacterial infection from loss of resistance. Of the author's two patients one has recovered, while the other, whose weight in 1920 was 148 pounds, weighed only 58 pounds in May, 1932. She refused food and was apparently content in her present condition: All authorities agree that change of environment, psychotherapy, and forced feeding are the essentials of management. From personal experience Clow endorses the postulates of Leede: that so long as the patient holds the center of the stage in a family too easily given to sentiment very little can be accomplished in rescuing the victim from her pitiable plight.—*New England Medical Journal*, October 6, 1932, ccvii, 14.

Vascular Syndrome with Vasodilatation of the Left Foot. Sympathetic Angioneuralgia.—There are a number of vascular disturbances of the extremities encountered in clinical practice, according to L. Gravier, that do not readily admit of classification under the heading of any of the well individualized syndromes, such as Raynaud's disease, chronic acrocyanosis and erythromelalgia. On the basis of a case history the primary nervous origin of these disturbances is demonstrated, as well as the extraordinary influence exerted upon them by acetylcholine. The patient had been suffering for several weeks with a constant burning pain in her left foot, upon the internal aspect of which was a red plaque extending from toe to heel, with swelling of the soft parts and onionlike thinness of the epidermis, suggesting neuritis of erythromelalgic type. The heart and great arteries were normal both clinically and radioscopically, but there was a lowering of arterial tension in the affected foot and in the entire limb. When iodine and sedatives had no effect upon the excruciating pain, recourse was had to acetylcholine as a last resort, the effects of which were magical, the patient immediately falling into a restful sleep that lasted for 12 hours. A course of 20 injections on alternate days was given, resulting in complete cure, with restoration of arterial tension in the affected member. The case, while resembling erythromelalgia, did not exhibit its chronicity, its paroxysmal character nor its reaction to heat and cold and changes of position; and it differed from painful claudication from vasodilatation, recently individualized by Van Bogaert, in that it was accompanied by swelling and presented a special topography. The possibility of a neuritis due to an arteritis is excluded, since no arteritis could

be demonstrated. Gravier inclines to give the name of angioneuralgia to the affection, which appears to be a simplified form of Raynaud's disease and erythromelalgia—simplified because surprised in an early stage. In view of its topography, it seems logical to suppose that the sympathetic disturbance was localized in the nerve fibers of the tibialis posticus, and to regard the case, in the absence of any arterial lesion, as one of neuritis of the periarterial tibial sympathetic plexus. This conclusion is not so revolutionary as it at first sight appears, and is in accord with the contemporary works of Leriche and Dechaume, who have shown the importance of nerve lesions in various vascular troubles of the extremities. The effect of acetylcholine, acting through its customary vasodilator mechanism, demonstrates the intricate blending of nervous and vascular factors in the syndrome.—*Journal de Médecine de Lyon*, September 20, 1932.

Multiple Biologic Tests in the Diagnosis of Tuberculosis.—There are certain cases, say M. Lucacer and G. D'Alessandro, writing in the *Riforma medica* of August 27, 1932, in which a diagnosis of doubtful tuberculosis is facilitated by applying multiple tests simultaneously or in close succession. The intracutaneous reaction to tuberculin is generally of little value for diagnosis, being the index only of a state of infection and not of the disease itself. But multiple intracutaneous reactions with progressive dilutions of tuberculin (perfectly harmless) and the tuberculin reaction at the level of the diseased organ increase the value of the test, offering in the first case the possibility of measuring the sensitivity of the individual person to tuberculin, and in the second revealing the different sensibility to the substance in different tracts of the skin, some nearer to and some farther from the disease focus. The result of a test with tuberculin diluted to 1:100,000 reveals the degree of "resistance," being positive only in subjects with circumscribed lesions, with good conditions of organic defense, and negative in all others. A test with tuberculin 1:5,000 at the level of the diseased organ itself produces a more intense reaction in 50 per cent of the cases than one of the same dilution carried out on the arm of the same side. Good practical results are obtained by determining three reactions, two with tuberculin 1:5,000 in the arm and second intercostal space on the suspected side, and a third with tuberculin 1:100,000. Fixation of complement, if the test is made on the day following the multiple tuberculin tests, will be stronger in 20 per cent of cases than if done before them, and hence will be more decisive. For the cases negative (about 15 per cent) both before and after the tuberculin test, some hints can be drawn from the multiple tuberculin tests by using the functional test of the reticulo-endothelium. These

cases are marked by an exquisite sensitivity to tuberculin (strongly positive with tuberculin 1:1,000,000) and offer an index of retention of electronegative substances (Congo red) which is still sensitive at the upper limit assigned to the productive and sclerotic forms (70-80 per cent). The velocity of sedimentation test carried out again on the day following the multiple tuberculin tests reveals in 50 per cent of cases either an increase or a decrease of about 10 mm., and can be used as an index of the course of the evolution of the disease. The functional reticulo-endothelial test, although complex and therefore not always practicable, offers a qualitative diagnosis, the retention of Congo red being greater in exudative and less in productive forms of tuberculosis.

Recurrent Boils.—Rupert Hallam, writing in the *British Medical Journal*, October 8, 1932, ii, 3744, discusses certain points relating to the etiology, complications, and treatment of recurrent boils. He recalls that to Pasteur belongs the credit of having discovered that boils were due to the *Staphylococcus aureus*, but it is the individual skin resistance to the staphylococcus which is of supreme importance in determining whether a person will suffer from furunculosis. An important etiological factor is the frequent presence, in cases of recurrent boils, of an intercurrent infection of the skin. This occurred in 31 out of 98 consecutive cases examined from this point of view. Sufferers from furunculosis are usually unaware of the complications which may assail them, yet there are probably more fatalities arising from it than from any other skin disease. The face and neck are recognized as a danger zone, but in addition surgeons meet with perineal and prostatic abscess and osteomyelitis followed by one or more boils. Prophylactic measures are, therefore, of definite importance. The reduction of carbohydrates should be insisted upon. The skin should be kept as dry as possible, since the self-disinfecting power of the skin is influenced by the amount of moisture present. It cannot be too strongly emphasized that the use of fomentations is a common cause of recurrence. The purulent discharge soaks into the dressing and staphylococci are spread to the neighboring follicles, where they are encouraged to multiply by the optimum conditions of heat and moisture. Hallam recommends the frequent cleansing of the surrounding skin with spirit and the direct application of pads of gauze soaked in spirit as a covering to the boil. Vaccines, though favored by some practitioners, have not lived up to their reputation, and in Hallam's experience yeast has proved useless. He has employed colloidal manganese hydroxide for many years and is convinced of its utility. Puncture with the galvano-cautery, injection of pure carbolic acid, and painting with iodine, each has its advocates,

but favorable results by these methods are by no means the rule. It is the prophylactic measures taken to prevent reinfection of the skin which are of greater importance.

Some Aspects of Rheumatism.—In the opinion of Charles Sundell the part played by infection in the causation of rheumatism has been grossly exaggerated. Irregularities of skin action and endocrine dysfunction are more important. The rheumatic individual is one whose nervous, mental, and physiological functions are unstable. A characteristic feature of acute rheumatism is excessive sweating. In chronic rheumatism sweating is abolished or irregular. The "acid sweat" of rheumatism is a tradition upon which was built the alkali therapy. An investigation, as yet unpublished, to determine whether there is an excess of lactic acid in the sweat of rheumatic individuals showed that there is no essential difference in the sweats of normal and of rheumatic persons. Sensitiveness to chill and patchy coldness of the surface of the body are common findings in the rheumatic state. The surface thermometer may record lowered temperature over these areas and there is evidence of capillary narrowing when the skin is examined under the microscope. There is also abnormality in the rôle played by nerve endings of the skin in originating afferent impulses by which bodily functions, such as blood pressure, are maintained or endocrine glands are called into play. It is possible to correlate in theory many of the features of the rheumatic state with the established effect of the thyroid and adrenal glands. For example, the lethargy of the rheumatic child, the fatigue of the adult, their impaired circulation and lowered body temperature have their counterpart in myxedema. Llewellyn and Bassett-Jones point out that thyroxine and adrenaline are derivatives of tyrosine, and that this is found in large quantities in the horny non-vascular layers of the skin. Possibly in the tyrosine supply of the skin may be found the clue to many of our problems.

If metabolic error is at the root of rheumatic manifestations, a cure cannot be expected from the administration of drugs. When, as with salicylates, their dramatic effect on the temperature and pain is taken as evidence of cure, they become a danger. For several years Sundell has employed purely physical measures. Left to themselves the fever and sweating of acute rheumatism effect a cure in four or five weeks; encouraged by hot packs or vapor baths their curative effect will be obtained much sooner. By exposure for one and a half to two hours in the vapor bath a temperature of 107° or 108° may be obtained without distress. The result is that the metabolic processes are quickened, the flow of blood and lymph is accelerated.—*Practitioner*, October, 1932, cxxix, 772.

LEGAL

PRIVILEGED COMMUNICATIONS

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

A member of the State Society recently wrote to your Counsel requesting an opinion upon two very interesting questions pertaining to the subject of privileged communications. These questions were referred by Legal Counsel to the Executive Committee and authorization obtained from it to answer the questions. Several members of the Executive Committee expressed the opinion that the questions were of sufficient interest to the profession generally to warrant the questions and the answer of Legal Counsel being published in the Legal Column of the NEW YORK STATE JOURNAL OF MEDICINE. The questions under consideration were the following:

"1. A private physician, in order to arrive at a diagnosis, referred his patient to a roentgenologist for chest examination. Said roentgenologist found and reported a tubercular condition of the lungs. Several years later an insurance carrier referred this same patient to the same roentgenologist for a chest examination. It appeared that about one year prior to that (or one year after the original examination), the patient met with an accident as a result of which he claimed a chest condition. Again the X-rays revealed a tubercular condition. However, from the second X-ray examination alone, without knowledge of the previous findings, it was impossible for the roentgenologist to state definitely that the pathology existed prior to the date of the alleged accident or not. Was it ethical and within his rights to divulge to the carrier the knowledge that he had gained from his first examination, two years prior, in which he acted in an entirely different capacity? As a witness before the court would he be permitted to give this information or would it be considered privileged?

"2. A very similar problem confronted a colleague of mine who in the course of his practice was called upon to treat a patient for vaginal bleeding. The bleeding was spontaneous and he found a condition responsible for it. Five months later, the same physician, who was also engaged in public liability examinations for an insurance company, by a mere coincidence, was requested by this company to examine the same patient. She was now attributing her vaginal bleeding to an accident. Wishing to avoid an embarrassing situation, he referred the examination to another physician. Was it ethical or permissible for him

to make this examination at the instance of the carrier, and, if so, was it permissible to include in the report such information that he derived from his original examination? As in the previous case cited, was it ethical and permissible for either physician to divulge to the carrier such knowledge that was gained from his original examination when he acted in the capacity of attending physician, or, was he bound to adhere to the restrictions of privileged communications? And, as in the previous case, how much information could he give as a witness in court? Would this be an instance where there existed an exception to privileged communications?"

The statute in this State relating to privileged communications is Section 352 of the Civil Practice Act, which reads as follows:

"Physicians and nurses not to disclose professional information. A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity; unless where the patient is a child under the age of sixteen, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto upon any examination, trial or other proceeding in which the commission of such crime is a subject of inquiry."

A reading of this statute discloses the fact that a physician may not disclose matters which he observed in treating or examining a patient, and this includes the nature of the examination, the diagnosis and the treatment itself, unless the patient has expressly or by implication waived the privilege of non-disclosure. The provision relating to the Criminal Law is not, of course, material to the questions under consideration.

In the first question, in the opinion of your Counsel, both the roentgenologist and the private physician under this statute would be prohibited from making any disclosure of the conditions found as a result of the first examination by the roentgenologist. Further, on the second examination the roentgenologist would be prohibited, without the patient's consent, from making a report to the carrier based in part upon his first examination. In our judgment, it could not be

claimed that there was a waiver of this privilege by reason of the fact that the patient consented to be examined by the same roentgenologist who had conducted the first examination.

In reference to the last question contained in the first statement of facts, to wit: "As a witness before the court would he (the roentgenologist) be permitted to give this information or would it be considered privileged?", this question has been fully answered by a decision of the Court of Appeals of this State in which the Court held that, "Where the plaintiff in an action brought to recover damages for personal injuries caused by the negligence of the defendant describes these injuries and their results and it appears that he has consulted or been treated by a physician in regard to them he waives the protection of Section 834 of the Code (now Section 352, Civil Practice Act)."

The Court then went on to state that in an earlier decision it had laid down the proposition that, "Where the patient tenders to the jury the issue as to his physical condition it must in fairness and justice be held that he has himself waived the obligation of secrecy which would otherwise exist. The ruling of the trial judge in the case before us, therefore, was erroneous and it was material. The plaintiff gave evidence as to her physical condition after an accident which she claims was caused by the negligence of the defendant. She stated that because of that condition she consulted Dr. W—, and described in

part at least what occurred at that consultation. Dr. W— was called upon by the defendant who sought to examine him upon the same subject. His evidence was excluded and an exception was taken."

We feel, however, that as a protection to the physician even in such a case a ruling should be obtained from the Court as to whether he should give the testimony sought to be elicited.

With respect to the second case cited above, in the opinion of your Counsel, the physician was correct in referring the patient in question to another physician for examination. Still, however, it cannot be said that it would have been unethical for the physician in question to have made the examination provided, however, he did not disclose without the patient's consent anything in connection with his first examination. With reference to the other points involved in the second case, the same rulings would apply as in the first case.

To avoid embarrassment in these and similar situations, we believe that the physician should not make the examination requested on the patient previously examined by him unless, prior to the second examination, a written consent is obtained from the patient to disclose the results of the first examination. In the absence of such consent, in our opinion the physician should advise the party requesting the examination to have it made by another physician acting independently of himself.

CLAIM OF NEGLIGENCE IN CYSTOSCOPY EXAMINATION

A specialist in Urology was consulted at a clinic conducted by him by a patient who complained of difficulty in urinating. The doctor put her on a table and after cleaning the vulva with soap and water and injecting 2% novocaine in the urethra, he inserted a cystoscope into her bladder. An examination with the said instrument showed that the fundus was normal except that there was a depression in the post-trigonal region. The trigonum vesicae was normal. The doctor then passed a catheter up to the kidney pelvis without any difficulty on the right side, but on the left side encountered an obstruction of unknown nature at a distance of about twenty-five centimeters. He then injected intravenously 1 cc. of phenolsulphonephthalein which appeared in about six minutes on the right side and in about five minutes on the left side. Specimens of the urine from each kidney were collected in order to examine whether bacteria was present.

Following this examination, the doctor directed the patient to be put to bed in the

hospital where the examination was made. The report made upon the specimen of urine was negative.

After the patient had been at the hospital for a few days she contracted a cold and when her bladder was irrigated by one of the house surgeons, his diagnosis was acute cystitis. A specimen of urine taken at the hospital about twelve days after the cystoscopy disclosed a trace of albumin and pus cells. About ten days thereafter the patient's condition having improved, she was discharged from the hospital.

The patient brought suit against the Urologist claiming that the cystoscopic examination had been made by him in a negligent manner so that the bladder was injured during the course of said examination, causing ulcerous condition of the bladder and an infection of the kidneys. When the case came on for trial, the plaintiff's attorney was not ready to proceed, and on motion of the attorney for the defendant the complaint was dismissed, which finally terminated the matter in favor of the doctor.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the State Society met at the Hotel Statler in Rochester on October 18, 1932, with all members present as follows:

Dr. James E. Sadlier, Poughkeepsie, Chairman.

Dr. W. H. Ross, Brentwood, Secretary.

Dr. George M. Fisher, Utica.

Dr. O. W. H. Mitchell, Syracuse.

Dr. A. J. Hambrook, Troy.

Dr. W. D. Johnson, Batavia.

Dr. T. H. Cunningham, Glens Falls.

There were also present Dr. T. P. Farmer, Syracuse, Chairman of the Committee on Public Health and Medical Education, and Dr. J. S. Lawrence, Executive Officer.

Private Practice by State Physicians: Drs. Ross and Johnson, the Committee on full-time prison physicians engaging in private practice, reported that the Committee had consulted the Commissioner of Corrections, and finds that it is usual for physicians in prison service to engage in private practice. Many of the physicians in prison service are on part time. The Department of Correction is friendly to the contention of organized medicine that physicians engaging in State service should not engage in private practice in competition with local physicians already established. The Deputy Commissioner of Correction said that his department felt that it had as much at stake in the quality of the prison service as organized medicine had in the interference of prison physicians with the private practice of medicine, and that his department would do all that it could to work out the problem for the good of the service as well as to be just to the medical profession.

The question of prison physicians engaging in private practice and possibly neglecting their major obligation for private gain has apparently not been raised before. The sub-committee reported that the foundation had been laid for further conferences on a friendly basis. The danger of neglecting the prison service brought to the front a possible criticism of the Department of Correction, because of the injustice of the State subsidizing a physician by paying him for his services, and then letting him do more or less as he wants to about determining the service for which he is paid. This is a major argument against a prison physician engaging in the private practice of medicine.

The prison situation has arisen because the system of prison medical service throughout the

State has been largely based upon the engagement of the doctor upon part-time employment. Now that the facts have been obtained, the next step will be to report the whole matter to the Executive Committee of the State Society for advice and counsel. Dr. Farmer advised that an effort should be made to get the Department of Correction to clarify its attitude toward full-time men in prison service on salary. It was brought out that it might be necessary to have the service of the Society's counsel, and that this should be included in the report to the Executive Committee.

Ratio of Hospitals to Population: The report on the ratio of hospitals to population was made by its chairman, Dr. O. W. H. Mitchell. It was as follows:

"On July 14, 1932, Dr. E. E. Haley addressed a letter to Dr. Chas. Gordon Heyd, President of the Medical Society of the State of New York, concerning the increase of Federal, State, County, and Municipal hospitals. The communication was eventually referred to a sub-committee of the Committee on Public Relations.

"The sub-committee desires to report that the problem presented by Dr. Haley centers about the General Municipal Law. If the law should be changed, or if it is being interpreted in ways not originally intended, the Counsel and Committee on Legislation should give attention to the problem.

"Your sub-committee suggested that the Executive Committee be so informed, and that Dr. Haley be notified of the decision of the Committee on Public Relations."

The opinion was reached that the whole matter is a legal question and that it should be referred to the Committee on Legislation. The Committee on Public Relations concluded that an evil exists, but that it was outside of the function of the Committee to correct it, since the first thing to do is to change the law regarding municipal and other hospitals. This, of course, will have to be preceded by a change in public sentiment. The whole subject was interpreted as another tendency toward State medicine. The Hospital number of the *Journal of the American Medical Association*—that of June 11, 1932, page 2142—contains an illuminating editorial on the great increase in the number of hospitals in recent years.

Popular Education on Cancer: Dr. Sadlier reported on the campaign of education regarding cancer now being carried on by the physicians of

the Dutchess-Putnam County Society. The members are now addressing about sixty organizations such as the Grange, Farm Bureau, clubs, and fraternal organizations on the early diagnosis of cancer. He said that it had been found that the doctor should first be educated as to his responsibility toward teaching the public regarding the early diagnosis of cancer. It was the opinion of the committee after discussion that this is a commendable activity for a county medical society, and it should be reported to other county medical societies.

Medical Examination of School Children: The Committee considered a series of newspaper articles setting forth the records of the several school districts of Steuben County in the medical examination of the school children, with special reference to the inequalities in both the character of the medical work and also in its cost. The Committee recognized the present chaotic state of the system of medical school inspection, and felt that the responsibility for improving conditions rests upon the educational authorities as well as the medical profession. Teachers, school boards of local districts, and the State Department of Education are all responsible for providing facilities for the doctors to make the examinations, and correct the defects; and also for the hearty cooperation of all the lay educational authorities with the physicians who make the examinations as employees of either the school or the parents of children.

Upon motion duly carried it was decided that the chairmen of the Committee on Public Health and that on Public Relations effect a contact with the State Department of Education and ask that better facilities be provided in schools and better cooperation of teachers, in order that school physicians may make more satisfactory examinations; that the result of the conference be published in the Journal; and that a bulletin be sent as a personal communication to the school physicians of the state, to be signed by the chairman of the Committee on Public Health and that on Public Relations.

It was also decided to ask the State Department of Education to send this request from the State Society to the Boards of Education and Trustees of schools throughout the state.

There was a further discussion regarding the examination of school children. It was the opinion of everybody that one dollar per pupil is a proper fee for the medical examiner. It was brought out by the discussion, however, that the work depended upon the man and not his fee; and also that a physician will do no better work for one dollar than he will for fifty cents.

County General Hospital: There was a discussion of the general hospital, built and operated by the county authorities, and particularly the relation of its medical staff to the physicians of the

county. Conditions in the Lewis County Hospital with a paid operating surgeon as head of the medical staff, were contrasted with a similar county hospital in Warsaw, Wyoming County, with an open staff. It was the opinion of the members of the Committee that the local physicians should assume the leadership in finding a solution of their hospital problems.

Reports from County Public Relations Committees: The afternoon session was devoted principally to a conference of the chairmen of the Public Relations Committees of six counties in the vicinity of Rochester.

Genesee County: Dr. M. P. Messinger, Oakfield, said that a county society was not usually informed of the usefulness of a Public Relations Committee, and that it did not understand that a Public Relations Committee was of service both to the public and to the physicians. He thought that a real need was that a county society should know more about the State Society and its committees.

Livingston County: Dr. Charles I. Newton, Genesee, outlined the health work in Livingston County, and reported on the doctor's clinics being held there under the health officer's direction. He said that physicians are in a position of leadership in Livingston County health work; and that the Supervisors are quite likely to abolish all public health services in Livingston County instead of economizing in these services. It was suggested that the Livingston County Medical Society formulate a program, go before the Board of Supervisors, and tell the Board that it is presenting a program that the physicians of Livingston County consider necessary for the health of the county. The County Medical Society of Livingston was advised that it should take charge of the matter and that a representative of the Public Health or the Public Relations Committee of the State Society will go with them and speak to the Board of Supervisors on the need of a health program sponsored by the County Medical Society.

Monroe County: Dr. Austin G. Morris discussed the overlapping of public health, charity, and medicine, and mentioned the increasing cooperation of family doctors with the official agencies of Rochester engaged in public health work.

Dr. Morris also stated that about four out of every five cases of tonsils and adenoids operated in the City of Rochester last year were charity cases and that it cost the City five dollars to get each one of these operations done; that a considerable number of these cases could pay a reasonable fee; that how to bring about a change in this situation was at present unknown. He said that a committee of the county medical society was working on the problem.

Ontario County: Dr. W. B. Clapper of Victor

discussed the value of retaining members in office and said that the Ontario County Medical Society had had the same secretary for thirty-six years. He said that a survey of all the towns in Ontario County regarding vaccination and administration of toxoid had been made, and that the Public Health Committee of the county, made up of laymen, supervisors, and physicians, had on it three physicians nominated by the County Society and appointed by the Board of Supervisors.

Wayne County: Dr. Ralph Sheldon, Lyons, said that his County Society is engaged in finding out the amount of welfare work that physicians in Wayne County are doing for nothing, and that when this is collected, it will be shown to the Supervisors and to the public. He said that the County Medical Society members are very friendly with each other.

Dr. Sheldon has examined two thousand school

children in Wayne County. He referred each one needing the correction of some defect by saying to them, "Please go and see your physician and see what he says about it." He called attention to the fact that a mandatory law compels the welfare official of the county to pay for the correction of defects if there is no other way for them to be corrected. He said that the Red Cross and fraternal societies in his county were a help in this work. All physicians in Wayne County charge one dollar for school examinations, and do one dollar's worth of work. Dr. Sheldon further said that in case the welfare official refuses to pay for the correction of defects, a reference should be made to the decision of the Attorney-General that welfare officials must pay for the correction of these defects if the need is certified to by the physician.

W. H. Ross, M.D., *Secretary.*

JAMES E. SADLER, M.D., *Chairman.*

GENESEE COUNTY

The annual meeting of the Genesee County Medical Society was held on October 20, 1932, at the Blue Bird Inn, Batavia, N. Y. The members of the Public Health Committee of the Board of Supervisors of Genesee County were our guests at the meeting and dinner.

The meeting was devoted to a discussion of public welfare problems, the chief speaker being Dr. Homer Knickerbocker of Geneva, who spoke on the experiences of Ontario County in Public Welfare work. He also spoke of a plan to take care of poor welfare work in Ontario County.

There was a general discussion on the various phases of inefficiency of administration of the public welfare law. The subject will be discussed with the Commissioner of Public Welfare.

A committee was appointed to meet with the Public Health Committee of the Board of Supervisors in order to develop a plan of public health activities for the County.

The annual election of officers took place and the following were elected:

President, Frank R. Hall, M.D., Batavia.

Vice-President, Ralph B. Smallman, M.D., Corfu.

Secretary-Treasurer, P. J. di Natale, M.D., Batavia.

Dr. Frank Hall, the incoming President, appointed the following committees:

1. Public Relations—I. A. Cole, M.D., Batavia, Chairman; G. H. Knoll, M.D., Le Roy; C. C. Koester, M.D., Batavia.

2. Public Health—Charles L. Davis, M.D., Batavia, Chairman; Ralph G. Streeter, M.D., Batavia; M. P. Messinger, M.D., Oakfield; C. D. Graney, M.D., Le Roy.

3. Legislation—C. M. Graney, M.D., Batavia, Chairman; Robert Wilson, M.D., Batavia; P. J. Di Natale, M.D., Batavia.

4. Medical Economics—S. R. Hare, M.D., Batavia, Chairman; H. M. Spofford, M.D., Batavia; E. G. Ribby, M.D., Byron; L. B. Manchester, M.D., Batavia; Peter J. Di Natale, M.D., Batavia.

5. Memberships—W. B. Manchester, M.D., Batavia, Chairman; H. G. Houze, M.D., Bergen; E. N. Morgan, M.D., Batavia.

6. Physio-Therapy—T. M. Steele, M.D., Le Roy, Chairman; H. A. Harvey, M.D., Batavia; W. C. Swasey, M.D., Batavia.

The following twenty members were present: Drs. Cole, C. L. Davis, Di Natale, Frazier, C. D. Graney, C. M. Graney, Hall, Hare, Houze, Johnson, Knoll, Koester, Manchester, Messinger, Morgan, Ribby, Smallman, Spofford, Streeter and Swasey.

P. J. DI NATALE, M.D., *Secretary.*

SULLIVAN COUNTY

The annual meeting of the Sullivan County Medical Society was held at the Lenape Hotel, Liberty, N. Y., on Wednesday evening, October twelfth, with the President, Dr. J. M. Rosenthal, of Monticello, in the chair. Officers for 1933 were elected as follows:

President, George F. Herben, M.D., Loomis.
Vice-President, Harry Golembe, M.D., Liberty.
Secretary-Treasurer, Luther C. Payne, M.D., Liberty.

Chairman, Legislative Committee, Ralph S. Breakey, M.D., Monticello.

Chairman, Public Health and Relations Committee, Harry Golembe, M.D., Liberty.

Board of Censors: Benjamin Abramowitz, M.D., Monticello; Harry Jacobs, M.D., Hurleyville; V. G. Bourke, M.D., Livingston Manor; Stephen W. Wells, M.D., Liberty; J. H. Moore, M.D., Loomis.

Physicians elected to membership were: Deeming S. Payne, M.D., Liberty; Lee Tompkins, M.D., Liberty; E. H. Kerper, M.D., Loomis.

Dr. Burton T. Simpson, Director of the State Institute for the Study of Malignant Disease, Buffalo, N. Y., read a paper on the responsibility

of medical men in the control of cancer. This paper was discussed at length and was well received by the physicians present.

Individual photographs were taken during the course of the meeting, in anticipation of the publication of a booklet commemorating the 125th anniversary of the Society, which organized in Liberty in 1809.

The next meeting will be held at the Monticello l'lks' Club on November 16, 1932.

HARRY GOLEMBE,
Chairman, Publicity Committee.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall on October 19, 1932, was called to order at 9 P. M. with the retiring President, Dr. Irving Smiley, in the Chair.

Dr. Smiley urged the members to give to the incoming President, Dr. William Klein, the same cooperation, support and loyalty that they gave to him during the past year. He then turned over the gavel to Dr. Klein, who thereupon took the Chair.

Louis Schneider was elected to membership.

Dr. L. A. Friedman, Chairman of the Committee on Public Health and Medical Education, presented the gist of an agreement between all high school principals in the Borough of the Bronx and the Bronx County Medical Society relative to the examination of the students.

Dr. B. H. Archer, Chairman of the Committee on Medical Economics, reported on the plans of the Committee for the coming year.

Dr. Weintraub reported for the Social Committee, urging the cooperation of the members in the matter of the coming beefsteak dinner for the benefit of the relief fund.

Dr. Moses H. Krakow was elected Delegate to the American Medical Association in the place of Dr. C. J. Egan, deceased.

Memorial resolutions were adopted in memory of Dr. Cornelius J. Egan and Dr. Ernst A. W. Wilkens.

Dr. William Klein then delivered his inaugural address as President of the Bronx County Medical Society. (This will be published in a future number of this Journal.—Editor's Note.)

The scientific program then proceeded as follows:

Dr. Marcus A. Rothschild gave a paper on the subject: "Acute and Chronic Rheumatic Heart Disease: Etiology, Treatment and Prevention."

I. J. LANDSMAN, *Secretary.*

GREENE COUNTY

The 116th annual meeting of the Greene County Medical Society was held in Cairo on October 11, 1932, with the President-elect, Dr. L. B. Honeyford, presiding. A dinner was served at 6:30 P. M. and immediately thereafter the meeting convened.

Dr. Edward P. McDonald of Albany presented an address on dysmenorrhœa, which was ably delivered and of great interest.

Mr. George Irwin of Catskill, Chairman of the Board of Managers of the Greene County Memorial Hospital, detailed the efforts made to establish a hospital in Greene County, and requested the appointment of a committee from the Medical Society to assist the Board of Managers in the further plans for the equipment and operating of the hospital, which is under construction and is expected to be ready for opening by March first.

Mr. Lowe, the architect of the building, was present and described in detail the specifications of the building, which is modern in every respect.

He also presented the plans for the members' inspection.

The following members of the County Society were appointed a committee to assist the Board of Managers of the Hospital:

Dr. L. B. Honeyford, Chairman; Drs. William M. Rapp, M. H. Atkinson, I. E. Van Hoesen, P. G. Waller, A. B. Daley, K. F. Bott, A. O. Persons.

The County Welfare Commissioner, Mr. H. L. Barker, was present and explained in detail the working of the Welfare Law in the County.

A resolution on the death of Dr. Andrew Van Slyke, the oldest active member, and the oldest health officer in the State, was adopted.

The following officers were elected for 1933:

President, L. B. Honeyford, M.D., Catskill. Vice-President, K. F. Bott, M.D., Greenville. Secretary, William M. Rapp, M.D., Catskill. Treasurer, M. H. Atkinson, M.D., Catskill.

WILLIAM M. RAPP, M.D., *Secretary.*

THE DAILY PRESS

REG'LAR FELLERS—Sure Proof.

By Gene Byrne.

From N. Y. Sun, October 31, 1932.

POISONING WITH TOADSTOOLS

The depression seems to be the only plausible explanation of the numerous persons who roam the country sides of Long Island, sometimes in trucks, gathering mushrooms for food, but are unable to explain how they recognize the edible varieties. The following item in the New York Times of October 27, shows the dangers to which the custom may lead:

"Babylon, L. I., October 26.—Three persons have died in twenty-four hours within a radius of one mile as the result of eating toadstools, which were mistaken for mushrooms. Two more are in the South Side Hospital in Bay Shore. The first victim was Mrs. Mary Sakalcka, 75 years old, who died yesterday at the home of her daughter, Mrs. Albert Laska, in the West Islip section. Mrs. Sakalcka came here from Newark, N. J., for

a visit, became ill after eating the toadstools and died next day.

"The Marcin family, living on South Fire Island Avenue, ate toadstools Saturday, and Mrs. Gertrude Marcin, 35, wife of Emil Marcin, died yesterday, while her sister-in-law, Miss Mary Marcin, 44, died early this morning. Emil, 37, his brother, Frank, 49, and their sister, Mrs. Emma Klein, 53, are ill. Mrs. Klein is convalescing at home, while the two brothers, more seriously affected, are at the hospital. They are expected to recover. The Marcin family moved here from Maspeth two years ago.

"It has been a custom here to gather wild mushrooms, but this is the first instance of poisoning. The toadstools were gathered in different parts of the town. The two families were not acquainted."

VITAL STATISTICS OF THE NOVEL

Homer's Iliad contains a long account of a battle beneath the walls of Troy, listing the names of the heroes, and the wounds which they received. Students have compiled interesting statistics showing that the ratio of fatalities and incapacitating wounds of the soldiers in the Greek army were practically the same as those in a modern army.

The New York Times of November third has the following suggestive editorial on some vital statistics derived from a study of the tragedies of life as depicted on the stage and in the modern novel:

"In these formulas, which condense Life into a hotel, or Life into a dinner party, or Life into

twenty-four hours, the vital statistics are truly extraordinary. Among a group of people gathered in a hotel lobby in a novel, or around a dinner table on the stage, the murder-rate will be 10 per cent, the suicide-rate 20 per cent, the divorce-rate 40 per cent, the seduction-rate 20 per cent, the bankruptcy-rate 60 per cent, &c.

"If life in New York City were really as life is like that in the novels and on the stage, we would have 500,000 homicides a year instead of 400, a million suicides instead of a thousand and other things in proportion.

"The true realist would take note of the fact that more people are probably bored to death at dinner parties than are shot or commit suicide."

RED WATER

Since physicians are trained in biology, they will be interested in the following scientific explanation of water turning into blood, taken from the *New York Sun* of October 20:

"Even as the waters of the Nile turned to blood, as told in the seventh chapter of Exodus, the waters of Long Island Sound have been running red in great patches this fall. Iodine has been blazoned as the cause. Impossible, say scientists, for that much iodine would be lethal.

"The red color probably is the same as the Nile discoloration, the same as famous classical instances of blood-red water mentioned by Strabo, Tacitus and other writers, namely, the dinoflagellates.

"The dinoflagellates are microscopic marine plants, says the Associated Press, identified repeatedly by scientists in the last hundred years as causes of outbursts of blood-red water, fresh and salt alike, all over the world.

"Dinoflagellates seem to be poisonous, but in fact are good food. They turn water red, but their color is greenish yellow. The latest studies of their peculiarities are from Dr. Thurlow C. Nelson of Rutgers University and Dr. G. W. Martin of Iowa State University.

"These little organisms are so small that one magnified 150 times is only about the diameter of the head of a pencil. Like the head of a pencil, it is flat, but not so perfectly rounded. It

forms one of the staple foods of shell fish, being one of the best for oysters.

"Sometimes through accidents of tide, winds, prolific breeding and the stickiness of a coat of gelatine covering their bodies, they mass in countless billions. That is when they turn the water red.

"The red color is not altogether understood. It is not any substance poured off like ink into the water. Instead, Dr. Nelson and Dr. Martin find that it is probably the reddish fluorescence of chlorophyll in the dinoflagellates.

"Chlorophyll is the universal green coloring matter in plants, a substance as important to them as blood to animals. Furthermore, chlorophyll is one of the most active, hard-working chemical substances, and its ability to emit a reddish fluorescence is well known to chemists.

"Even when massed, the dinoflagellates are not poisonous. But they asphyxiate and sometimes kill large quantities of fish, by extracting the oxygen from the water. Like other plants the dinoflagellates give off oxygen during daylight, but absorb it at night. Fish trapped among clouds of them at night are likely to become too exhausted to escape.

"The 'death' of a dinoflagellate is dramatic. It comes to rest, and then almost immediately disintegrates."

FLYING AS A CURE OF DEAFNESS

Newspaper reports of alleged cures of deafness delude the people into going to high altitudes in airplanes and submitting to long dives in order to subject their ears to rapid change in air pressure. This procedure was condemned by Army flight surgeons, who spoke at the scientific meeting of the Associated Physicians of Long Island on October 25, at Mitchell Field, the headquarters of Army aviation in the Eastern United States. The opinion of the medical officers is reported in the following item in the *New York Sun* of October 26th:

"That stunt flying never has and never will restore hearing was the principal theme of addresses by several physicians. Major Chauncey L. Chase said he once saw a deaf man make a 3,000-foot dive in an airplane, without effect. Major A. Edward Sherman supported him, saying repeated tests had shown that stunt flying had no value as a corrective of deafness. In fact, he added, it does more harm than good, and physi-

cians in the Army Air Corps do not recommend it.

"Dr. Louis H. Bauer of Hempstead, formerly head of the medical section of the aeronautical branch of the United States Department of Commerce, said he could see no reason why stunt flying should be expected to cure deafness.

"Dr. Bauer explained that the aeronautical division of the Department of Commerce has a rule against stunting with a passenger. When he was with the department, he added, many requests were received for waiver of this rule in behalf of deaf persons who sought to try the 'cure' but each request was answered with a telegram in which it was pointed out that nothing was to be gained by such an experiment.

"Dr. Bauer said that he knew of rare cases in which fright brought back a person's hearing (Referring to deafness due to hysteria), but he advised that there are other and safer ways of frightening a deaf person than taking him on a stunt flight."

BOOKS RECEIVED

Acknowledgement of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

GASTROINTESTINAL TRACT. By WILLIAM GERRY MORGAN, M.D. 12 mo. of 259 pages, illustrated. Philadelphia, J. B. Lippincott Company, [1931]. Fabrikoid, \$5.00. (Everyday Practice Series.)

NEW AND NON-OFFICIAL REMEDIES, 1932. Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1932. 12 mo. of 485 pages. Chicago, American Medical Association [1932]. Cloth, \$1.50.

ORTHOPEDECS IN CHILDHOOD. By WILLIAM L. SNEED, M.D. 12mo of 318 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1931. Fabrikoid, \$5.00. (Everyday Practice Series.)

MEDICAL CLINICS OF NORTH AMERICA. Vol. 16, No. 2, September, 1932. (Chicago Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.

DIAGNOSIS AND TREATMENT OF DISEASES OF THE THYROID GLAND. By GEORGE CRILE, M.D. and Associates. Octavo of 508 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$6.50.

BOOK REVIEWS

SCHIZOPHRENIA [Dementia Praecox]. An Investigation of the Most Recent Advances. The Proceedings of the Association New York, December 27th and 28th, 1929. Editorial Board, GEORGE H. KIRBY, M.D., and others. Octavo of 246 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1931. Cloth, \$4.00. (Association for Research in Nervous and Mental Disease. Vol. X of a Series of Research Publications.)

This book is Volume X of a series of research publications issued by the Association for Research in Nervous and Mental Disease. It is divided into four sections:

- Section I—Clinical Investigation.
- Section II—Pathology.
- Section III—Prognosis.
- Section IV—Treatment.

The section on Clinical Investigation has papers on the "Distribution Ratio of Bromides" wherein the results of the determination of the bromide distribution ratio between the blood and the cerebrospinal fluid in 210 cases of Schizophrenia are reported. Another paper on the "Deficiency of Catalytic Iron" showed iron to be deficient in the cortical ganglion cells in schizophrenia and the significance thereof. There are other papers on a neurocirculatory test for early diagnosis, environmental factors, and a personality study in schizophrenic patients.

In the discussion of the pathological anatomy, Dr. Spelmeyer emphasizes the fact that Schizophrenia is an organic disease, though the anatomical diagnosis and differential diagnosis necessary to isolate the process and establish it as an entity has not been worked out.

In the paper on prognosis several points are brought out. In general an acute, stormy onset means a relatively favorable prognosis, whereas the insidious onset means the reverse. The most fruitful sources of prognostic information in a series of 25 cases were the personality, the evaluation of toxicity and exhaustion, a close analysis of the precipitating situation and the stage of onset.

In the paper on treatment Dr. Zeboorg emphasizes the fact that Dementia Praecox is being treated psychotherapeutically, dealing with the reality principle first and then the analytical situation. There is a statistical analysis of the report of records and improvement by various investigators.

This volume represents the most modern concepts of this important subject. It is concise, carefully arranged, and the papers are conservative in their statements. It should be of interest to all physicians as its scope is unlimited.

S. S. LAMM.

PHYSIOTHERAPY: ITS PRINCIPLES AND PRACTICE. By F. HOWARD HUMPHRIES, M.D., F.R.C.P., and RALPH E. STUART-WEBB, M.B., B.S. Octavo of 399 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$4.50.

In this excellent volume the author has succeeded in condensing a surprising amount of information in comparatively small space. The book is divided into two parts, the first dealing with the underlying principles of physiotherapy. It includes a very complete description of the fundamentals of the various modalities used, and an equal description of apparatus both new and old. The second part is devoted to an inclusive exposition of the practical application of physiotherapy. Treatment of the various parts of the body and the different pathological conditions is covered in detail.

Careful classification renders the volume of use as a reference work also. The book is well written and illustrated and clearly printed, and can be highly recommended to the practitioner as well as to the student.

JEROME WEISS.

MICROSCOPIC SLIDE PRECIPITATION TESTS FOR THE DIAGNOSIS AND EXCLUSION OF SYPHILIS. By B. S. KLINE, A.B., M.D. Octavo of 99 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1932. Cloth, \$2.50.

There is an increasing interest on the part of laboratory workers and clinicians in precipitation tests for syphilis. In addition to specificity, two things would seem to be indicated in such tests, namely, simplification of test (not so much for convenience as to reduce chances for error) and greater knowledge of the principles involved.

In this monograph of 100 pages, Dr. Kline gives a complete discussion of his slide precipitation tests for the diagnosis of syphilis. He devotes about 25 pages to a discussion of the principles of flocculation with a review of the work of other investigators. This is a very valuable section and includes microphotographs of different types of reaction. In the remaining pages the author describes in great detail the technic of his tests and their clinical evaluation. This is a working manual for the serologist who wishes to try these tests.

E. B. SMITH.

ANTE-NATAL CARE: Including the abnormalities associated with pregnancy and a section on post-natal care. By W. F. T. HAULTAIN, O.B.E., M.C., and E. CHALMERS FAHMY, M.B., F.R.C.S.E. Second edition. 12mo of 127 pages, illustrated. New York, William Wood & Company, 1931. Cloth, \$2.25.

In the preface to this second edition of Ante-Natal Care, the authors state that this edition contains a description of the Aschheim-Zondek test for pregnancy and in response to numerous requests a chapter on Post-Natal Care has been added.

In so doing they have considerably enhanced the value of this book which is now more complete and should be of benefit to the general practitioner and those who have charge of ante-natal and post-natal clinics.

This small volume of about 121 pages is probably the only book of its kind which is especially devoted to this subject and should be a welcome addition to any well-rounded library.

It describes the routine of the clinic at the Royal Maternity and Simpson Memorial Hospital, Edinburgh, including diagrammatic sketches of the layout in the ante-natal department.

There are excellent chapters on the diagnosis and hygiene of pregnancy.

Pelvimetry has been given competent treatment, deviating from the custom in this country, however, by giving the measurements in inches instead of centimeters.

The management of contracted pelvis cases is discussed in some detail, but in this reviewer's opinion too much stress is laid upon the induction of premature labor in such cases, for in this country induction of labor for contracted pelvis is practically obsolete.

Albuminuria, eclampsia and chronic nephritis and their management is adequately discussed.

The hemorrhages of pregnancy and the subject of pain during pregnancy, with its possible causes, are handled in a complete manner.

The chapter on Post-Natal Care is a valuable addition to this book.

M. V. ARMSTRONG.

OUR NEIGHBORS

ANNUAL MEETING IN WISCONSIN

The October number of the *Wisconsin Medical Journal* contains the following description of the ninety-first annual meeting of the State Medical Society of Wisconsin:

"With over nine hundred twenty-five physicians registered during the three-day session, the State Medical Society of Wisconsin set a new record for attendance at its annual meeting at the ninety-first anniversary session in Milwaukee, September 13th-16th. The entire fourth and fifth floors of the Schroeder were given over to the meeting rooms for the one hundred twenty presentations made during the three days.

"Despite the very large attendance and extensive program with its section meetings, every session ran within five minutes of schedule throughout the entire three days and over five hundred were present for the last address on Friday afternoon presented by Dr. Julius Bauer of Vienna.

"A feature of the meeting was the round table luncheon conferences held on Thursday noon which, although expanded to accommodate two hundred forty members in twelve separate discussion groups, was still found to be insufficient to accommodate all who desired to attend these popular meetings. Over three hundred members were in attendance at the hospital clinics which opened the scientific meeting from eight to ten on the first day.

"The House of Delegates was literally flooded by the major questions presented at this session. Meetings were held on both Tuesday and Wednesday evenings, and the final session was held on Thursday morning, September 15th. Important actions of the House are summarized following:

"1. Adopted unanimously the report of the special committee to study admissions to the State of Wisconsin General Hospital, and instructed the committee to proceed towards the accomplishment of the ends outlined in this report.

"2. Adopted the progress report of the special committee on the distribution of medical services in Wisconsin.

"3. Referred to the Council, after referendum vote in the county societies, the question of whether the Society should favor legislation or conferences with insurance carriers as a means of securing for the injured under the Workmen's Compensation Act, free choice of physicians among all willing and capable.

"4. Adopted all committee reports as published in the August issue of the *Wisconsin Medical Journal* with but two minor changes.

"5. Voted unanimously to retain \$15.00 dues that the Society might carry into effect the progressive program outlined for 1933."

The State Society gives a gold seal of the Society to members selected in accordance with the following plan:

"Among this host of contributors to our achievements there stands out, from time to time, one or two who have not only rendered long and exceptional services and discharged their duties faithfully, but have actually given of themselves far beyond the call of office because of the love of the work and the feeling of satisfaction in doing something more than that required for their Society, their brethren in medicine, and the people of this State."

The Society gave the seal to four members, and also gave it to a woman member, Dr. Mina Brooks Glasier, of Bloomington, with the following citation:

"A daughter of Wisconsin, a teacher in its public schools, a physician for fifty years, the wife of a physician, the sister of a physician, the niece of a physician, a past worthy grand matron of the Wisconsin Order of the Eastern Star, a past president of the Grant County Medical Society and now rounding out thirty consecutive years as its secretary; a member of the State Board of Health, now in the eighth year of service; and a mother,—for your distinguished service in your home, in your profession, to your profession and to the people of this commonwealth, we your fellow members, give you this seal of our Society as a token of your achievements and our esteem.

ANNUAL MEETING IN WASHINGTON

The October issue of *Northwest Medicine* has the following editorial comment on the annual meeting:

"The annual meeting of Washington State Medical Association, held at Tacoma, September 12-14, was noteworthy and in three particulars epochal. It was entirely economic, and marked

the beginning of a unified acceptance of the problem of medical economics, and a study program for the future. It established for this association the new and highly valuable educational department of scientific exhibit and demonstration; and it will become historic because it marked the

(Continued on page 1332—adv. xii)

Why We Supply DEXTRI-MALTOSE Only in Powder Form

Syrup Contaminated by Exposure to Air

FIG. 1. The can of syrup* shown above was opened for one-half hour in a bacteriological laboratory to permit withdrawal of a portion of its contents. This was done with sterile pipettes. The can was then covered tightly and stored. One month later it was again opened for the purpose of obtaining more syrup but examination revealed the heavy mold growth pictured above. Growth also developed in two other cans purposely exposed for a brief time. Mold grew in one as early as 7 days after the can was opened.

No Growth in DEXTRI-MALTOSE After Exposure to Air

FIG. 2. This can of Dextri-Maltose was opened for one-half hour to approximate conditions under which accidental contamination appeared in syrup at left. To make the test more severe, the Dextri-Maltose was also heavily inoculated with a micro-organism which had previously produced thick growth in syrup. The can was then closed and not opened for 40 days, at which time no growth was visible. Later, the can was opened 4 or 5 times for a total exposure of about 1 hour, without the slightest evidence of growth.

Thrush Organism Grows in Syrup — Fails to Grow in DEXTRI-MALTOSE

As a more stringent test, syrup* was inoculated with the pathogenic thrush organism. A thick mold growth developed and the inoculum grew after 17 days. In sharp contrast, Dextri-Maltose inoculated with the same strain was entirely free from growth. These tests were conducted in a modern bacteriological laboratory. Considering that the thrush organism and other molds grew so rapidly in syrup under these

conditions, how much greater is the chance for contamination in the average household where the syrup can would be opened at least once daily! Therefore, because carbohydrate preparations in syrup form not only attract insects and dust but also offer a fertile field for the growth of fungi, we shall continue to supply Dextri-Maltose only in powder form.

*A maltose-and-dextrin syrup experimentally made and studied but not marketed.

Maltcao Builds Health and Energy

Maltcao is ideal for those of your patients who require a concentrated food drink rich in organic salts. This scientific food preparation with a delicious chocolate taste builds health and energy because it contains calcium, iron and phosphates in organic combination.

It is the only chocolate food drink, so far as is known, that contains these added organic salts. Young and old enjoy drinking Maltcao with meals or at bed-time.

Maltcao
BUILDS FOR THE YEARS AHEAD

(Continued from page 1330)

beginning of the Woman's Auxiliary to the Washington State Medical Association.

"One year ago there was general discontent, demand was made on all sides for the correction of many evils, and few were in agreement as to just what should be done to bring order out of chaos. At the close of this annual meeting the mental attitude of the profession is changed. Those who saw no hope are willing to withhold active opposition to reorganization efforts; those who were most conscious of the economic and social problems that beset the medical profession are either hopeful or enthusiastic over the possibilities of relief; and, most important of all, unity prevails.

"The studies of the past year have relegated the previously paramount question of contract practice to a minor position, because they have shown that this is only a part of the big problem that confronts organized medicine, and physicians everywhere are less disposed to take a radical position on this question. Antagonisms have been softened, individuals are less disposed to insist upon their right to practice as they please, and the principle, that what is best for the entire profession is best for the individual physician, has gained some measure of acceptance. There was, perhaps, no single note sounded at this meeting which did more to bring the members to a full realization of the need for unity than the somewhat guarded statements of Drs. Nathan Sinai and R. G. Leland, to the effect that unless the medical profession united in earnest cooperative study and developed an improved plan of medical care, they would be submerged by social insurance within a period of two years.

"Two forward steps were made and definite action taken. A new Medical Practice Act to replace the existing law was proposed and adopted. This was proposed, first, because it will make it possible for the medical profession to regain control of its own members; second, because it eliminates politics; third, it provides funds and machinery for the effective enforcement of its provisions; and, fourth, it places organized medicine in a position to take leadership in the supervision of scientific medicine and control of public health, to the end that public welfare and safety may be advanced. Every item in this new bill is in the interest of public welfare, and cannot in any sense be looked upon as class legislation. It is fair to all physicians and upholds the high standard of ethical medicine.

"The second forward step concerns the proposal for the amendment of that section of the Medical Aid Law which deals with contract practice, and is designed to correct certain abuses of the system which are deplored by all parties concerned. The most essential element in this bill is the proposal to establish a non-political advisory board for the Department of Labor and In-

NEWSPAPER PUBLICITY IN MINNESOTA

The minutes of the Minnesota House of Delegates held on May 23 and printed in the September issue of *Minnesota Medicine* contains five pages of the report of the Editorial Association Committee and its discussion. The Committee establishes contacts with the newspapers. Mr. Roy Dunlap, representing the newspapers, spoke on newspaper advertising by medical societies, and said:

"We cannot hope to present medical education without your assistance. We in St. Paul have been very fortunate. This question was thrashed out some years ago, and the Ramsey County Medical Society appointed a committee to work with the newspapers, with the result that when anything new bobs up in the way of a supposed cure, we immediately refer it to the doctor's committee, and are able to print it with a note of caution from the doctors that this thing is rather new, and we had better wait until it is further developed and further experiments have been made before we accept it. We all know that the man who is ill and in desperate straits, is a drowning man grasping at a straw when a new cure appears.

"I am going to leave these advertisements with you. I want you to study them. I want you to know they are done in the most dignified manner. There is nothing there that is going to in any way cross the doctor's code of ethics. There is nothing in there that they would be ashamed to have appear in your local newspapers, because the whole idea is educating along two lines: Guard your health, call the doctor when you are ill, and pay the doctor, and I am sure if this campaign is run in that way, in due time you will see it will have a wonderful result."

Dr. O. E. Locken, of Crookston, said:

"We are now running a series of advertisements in the paper of Crookston that is paid by the two clinic groups in that town. We are advancing some information in regard to present medicine. The first advertisement, for instance, stated that the doctor is not only giving you his time and his judgment, but he is giving you something that costs money when he gives you an examination, because he is using scientific instruments that cost a good deal of money, and for that reason he has to expect that you pay for that service. The advertisement which came out last week said, 'You should add a sixth item to your budget.' To the necessity of budgeting groceries, taxes, and so on down the list of fundamentals, that they should add something to their budget for medical attention.

"We had very interesting reactions. I had a woman say, 'You didn't send me a bill. I called you out at three o'clock in the morning. I know you people are entitled to your money.' We

have had men write in and say, 'I have noticed your advertising, which is O.K. with me,' and send in their check. People in our community are getting to feel, when you have given your services, 'How much will the charge be?' They go into the business angle more than they have in the past.

"It is done in a purely dignified manner. I find when I am through talking to people I don't feel I have to apologize when I ask them to go into the business office and hand them the bill. I used to. I felt as a dignified physician I should only talk to them on scientific matters. I found that when my own psychology changed it was easier to talk to the people about that. I feel sincerely that there is a better relation between my patients and myself now than there was a year ago when I hardly dared mention the subject of money to them. We have a finer relationship between the patient and the doctor.

"Out in the country we are getting to have the reaction that the specialists in the city have. When the people come in they expect to pay, and have a very high respect for our services.

"Every week a lot of information has been sent out by the Minnesota State Medical Association to all the newspapers in the state and our editor has thrown every one of those in the waste basket every week for the last three or four years. We have talked to him about it. He said, 'Why should I be interested in your organization when you are not interested in mine?' We feel we can go to him (he is a good friend of ours), because we have spent a little money with him and expect him to put in this legitimate information which the state medical society is sending out, and he will. I know he will because the bankers of that territory said they would buy no more printing material from him if he continued to publish on the front page every time a bank closed in that territory. For two years there has never been an item in the Crookston paper that any bank had closed. These men understand economics, and we propose to talk to them in the language they can understand."

ANNUAL MEETING IN INDIANA

The October number of the *Journal of the Indiana State Medical Association* contains the following editorial on the annual meeting held September 27-29, 1932:

"With a total registration of 904, a mark well up to the average even in normal times, except when the convention is held in Indianapolis, the eighty-third annual session of the Indiana State Medical Association at Michigan City, September 27th, 28th, and 29th, might be said on the whole to have been a very successful meeting. The low

4 New Concentrated Vitamin Products

Vitamin A alone

Name Smaco Carotol Product No 505

Description. Carotol is a 0.3% solution of carotene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use

Taste Entire absence of all fishy taste makes it acceptable to your patients

Color Deep red, due to carotene

Potency Ten drops contain one thousand International Units of vitamin A

Dosage Three to five drops daily for infants and young children. Five to ten drops daily for adults

Package 15 c. dropper top, protectively-colored bottles, in special cartons to shield it from the light

Cost Because of its high potency and the small doses required, it is an inexpensive source of vitamin A, in spite of the fact that it is the only product containing vitamin A alone

Indications For conditions caused by vitamin A deficiency and cured or prevented by adequate vitamin A or carotene dosage

Vitamin D alone

Name. Smaco Concentrated Vitamin D Product No 515

Description. This product is Natural Vitamin D, being a highly potent extract of the antirachitic principle of cod liver oil

Taste Palatable and free from objectionable taste

Color Nearly colorless

Potency Ten drops are equal in vitamin D potency to three teaspoons of standard potent cod liver oil

Dosage Average prophylactic dose, ten drops daily. Average curative dose, fifteen to thirty drops daily, depending on severity of case

Package 5 c. and 50 c. protectively colored bottles

Cost Approximately the same as that current for equivalent vitamin D dosages of plain cod liver oil

Indications For the prevention or cure of rickets and spasmophilia, and where ever vitamin D therapy is required, such as tetany and osteomalacia

Vitamins A and D together

Name Smaco Vitamins A and D Product No 525

Description Smaco Carotol and Smaco Concentrated Vitamin D are combined in this product, providing both vitamins A and D in concentrated form for therapeutic use

Taste Palatable and free from objectionable taste

Color Red, due to carotene

Potency Ten drops are equivalent to one thousand International Units of vitamin A plus the vitamin D potency of three teaspoons of standard potent cod liver oil

Dosage Ten drops or more daily depending upon individual requirements

Package 5 c. and 50 c. protectively colored bottles

Cost Approximately the same as current prices for equal dosages of other vitamin concentrates

Indications Wherever vitamins A and D are required together in palatable form and small dosage

Smaco Cod Liver Oil fortified

Name *Smaco Cod Liver Oil (with Carotene and Concentrated Vitamin D) Product No 510

Description A high grade cod liver oil fortified with vitamin A of vegetable origin (carotene) and natural vitamin D described in the second column

Taste Although carotene is not a flavoring agent, nevertheless the addition of carotene noticeably improves the flavor

Color Deep red, due to carotene it contains

Potency. One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod liver oil plus 1,000 International Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil

Dosage. One teaspoon daily for average individual needing vitamins A and D

Package. Four ounce protectively colored bottles packaged in special cartons to shield from light

Cost Approximately one half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil

Indications Wherever a more palatable, concentrated cod liver oil is indicated (Only one third as much is required as plain cod liver oil)

New Vitamin Therapy Possible

Up to this time it has not been possible to prescribe vitamin A alone as in cases where vitamin D is not required or is already supplied by sunshine, ultra violet light, viosterol, etc. Smaco Carotol makes possible the administration of Primary Vitamin A in drop doses thus permitting the physician to regulate the dosage to meet individual requirements

Smaco Vitamin D is natural vitamin D. It is not an irradiated oil and not a cod liver oil concentrate but rather a highly potent extract of the antirachitic principle of cod liver oil. It is produced for therapeutic use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University

It now becomes possible with these new Smaco concentrated vitamin products to prescribe vitamin A alone, vitamin D alone or vitamins A and D together in drop dosages and palatable form, thus permitting the physician to prescribe any desired potency of these vitamins and any desired combination

Smaco Cod Liver Oil fortified with primary vitamin A and natural vitamin D is a product which physicians who use this Smaco product—namely—ch as much as the same vitamin content of plain cod liver oil and only one third the dosage is required

Smaco Products, like S. M. A. are ethically advertised and carefully distributed through prescription pharmacies. No dosage is given in the label. Each package carries its statement. Use as prescribed by your physician.

Information and prices on crystalline Carotene (up to FIVE THOUSAND T. M. E. S. the vitamin A potency of cod liver oil) for research purposes furnished upon request

point of the convention came on the opening day when more than one hundred golfers were rained out, and the high point of the session undoubtedly was the banquet on the final night with Dr. Dean Lewis, of Baltimore, president-elect of the American Medical Association, former Congressman Fred Landis, of Logansport, entertainer supreme, and Mrs. Walter Jackson Freeman, of Philadelphia, president of the Woman's Auxiliary to the American Medical Association, as guests of honor and principal speakers.

"Although not housed to the best advantage, due to the insurmountable handicaps of the convention hall which allowed much noise that even the use of mechanical loud speakers could not override, the scientific meetings without exception were well attended and the essayists well received. The instructional courses, an innovation this year, on the first morning of the meeting, received the hearty approval of the audience. These courses had a tremendous appeal as they were short on theory and long on practical information. They gave each physician something he could apply to his own practice. So splendid was the material presented by the three sections at this instructional hour that the general expression was, 'It is difficult, with the programs in the three sections going on simultaneously, for a man to choose the speaker he desires to hear.'

"More of the program was devoted this year to the discussion of medical economics than ever before, President F. S. Crockett devoting practically his entire address from the chair to that subject, while the whole afternoon on the last day of the session was given over to this problem.

"The principal duty before the Council was the selection of an editor and an editorial board to carry on The Journal work with that high standard established through the last twenty-five years of editorship by the late Dr. Albert E. Bulson. Dr. E. M. Shanklin, of Hammond, was selected editor by the Council with an editorial board composed of five men."

SCHOLARSHIP OF MEDICAL STUDENTS IN COLORADO

The August number of Colorado Medicine strikes a pessimistic note in an editorial on the scholarship of medical students. It deplors the lack of real instruction in anatomy and physiology in high schools, when commonplace health and habits constitute the bulk of the teaching. It suggests the admission of first-year students to clinics, as is done in Yale, in order to show them what the basic work of the first year is all about. The editorial reads:

FREDERICK T. SEWARD, M.D., Res. Phy.

(Continued from page 1336—adv. xxi)

"The appalling number of students failing in our medical schools causes us to contemplate the etiological factors. Medical educators appear to be dissatisfied with the mental equipment of their entering classes; this is, of course, a reflection upon preliminary education. The dissatisfaction has been reflected in the altering and increasing pre-medical education required during the past generation.

"Dr. Iran E. Wallin, professor of anatomy in the University of Colorado School of Medicine, has prepared an enlightening paper upon this subject. Dr. Wallin has for years sought and analyzed the causes of poor medical scholarship. About 30 per cent of our freshman students barely pass; approximately 40 per cent flunk their first examination in gross anatomy. Analysis indicates that the majority of these failures follow memorizing rather than learning by understanding. There is a striking lack of curiosity which would naturally make learning a pleasurable task. A deplorable absence of child-like curiosity has been commented upon by Dr. Wallin; what has become of that desire to know? The students' entire educational experience has been based upon the passage of examinations and not upon genuine interest in the subjects.

"Even with a biological preliminary education, there is an unbelievable ignorance of the human body. Anatomical and physiological subjects have been stricken from the curricula of most high schools. There is, then, no foundation upon which to build the medical vocabulary and immense amount of advanced detail. The student is bewildered and often enters the examination room on the verge of hysteria and unable to utilize the knowledge he has acquired, especially in the answering of practical questions.

"We note in our leading teaching institutions an attempt to give the students the earliest possible practical observations and experience. Admission to the clinics and contact with the patients is greatly appreciated by the underclassmen. Nothing will so increase their interest and insight; it will be necessarily result in improved scholarship.

"The local medical school is planning to request each of its candidates for the freshman class to study Harvey's 'Simple Lessons in Human Anatomy.' Here is a valuable suggestion, applicable also, by way of review, to those of us engaged in the practice of medicine."

NEWS NOTES IN NEBRASKA

Suggestions are sometimes made that this Journal print personal notes regarding the members of the State Society, on the ground that they will be of general interest. Some State journals print personals regarding the professional activities of

physicians. The *Nebraska State Medical Journal* of October has a page describing doctors' activities which are in no way connected with medicine, such as the following items:

"Dr. J. W. Carr has located at Ulysses.

"Dr. T. J. Kerr, North Platte, recently suffered a broken leg.

"Dr. Charles F. Moon, Omaha, spent his vacation in the Black Hills.

"The village of Surprise is without a physician, but has two drug stores.

"Dr. C. C. Shepard and family, Ord, have gone to California for an indefinite stay.

"Dr. A. J. Mullman, Talmadge, has sold his interests at that place to Dr. T. L. Grizka.

"Dr. F. J. Condon and family, St. Paul, visited relatives at Fort Dodge, Iowa, the latter part of August.

"Dr. and Mrs. B. B. Davis, Omaha, covered 6,000 miles in a motor trip east during the summer.

"Dr. D. D. Hughes, Fairbury, suffered the loss by theft from his car of an instrument and medical case.

"Dr. A. D. Mahaffey has sold his good will at Valparaiso to Dr. J. W. Hervert of Lincoln, and will move to Texas.

"Dr. Esther McEachron, Omaha, contributed

an article, 'Physical Examination for the Healthy Child,' to *Hygeia* for September.

"Dr. and Mrs. Charles Lucas, Shelton, visited the boyhood home of the doctor at Bloomington, Ill., recently, and also historic places in Springfield.

"O. Gilbert Peskin, Omaha, was sentenced to thirty days in jail for practicing medicine without a license. He was conducting a so-called 'health home.'"

CHIROPRACTIC IN MASSACHUSETTS

The *New England Journal of Medicine* of September first contains the following circular letter which had been sent out by the Legislative Committee of the Massachusetts Medical Society:

"The Massachusetts Medical Society, founded in 1781 and now numbering about 4,800 members, is confronted with an important problem and asks for your cooperation.

"The chiropractors, a medical cult who call themselves 'Drugless Healers,' have obtained the requisite number of signatures of legalized voters and their Initiative Petition will appear upon the November ballot. Chiropractic is defined in said petition as 'the science or practice of locating and adjusting by hand the malposi-

tions of the articulations of the human spine.' For the past ten years all of their bills have been defeated by legislative action and in 1932 they were given leave to withdraw by a vote of 151 to 50 in the House and 21 to 13 in the Senate.

"The present law provides a single standard for all who practice the healing art in this Commonwealth, and is satisfactory to all graduates of recognized medical schools including those from homeopathic and osteopathic schools.

"The chiropractors ask for special privileges although our form of government abhors class legislation. Chief Justice Rugg of the Supreme Judicial Court has rendered an opinion in the case of Commonwealth vs. Zimmerman that a chiropractor practiced medicine without being lawfully authorized.

"After an individual has successfully passed the examination of the Board of Registration in Medicine, he should be permitted to practice the method for which he is best fitted, be it allopathic, homeopathic, osteopathic or chiropractic. The sick, injured and infirm must be protected from those who are not able to comply with the present law.

"An editorial in the Boston Herald of June 30, 1932, said in part, 'We should not lower the bars for the benefit of those who cannot meet our reasonable requirements. New Jersey did some years ago, and in one year 536 chiropractors were licensed. The next year New Jersey put the bars up again.'

"We feel that this problem is a mutual one and that your organization should become active in opposing this petition. We would like to present more information at a personal conference if you are interested."

MEDICAL STUDY IN RHODE ISLAND

The September issue of the *Rhode Island Medical Journal* points out the opportunities for medical study in the State, even though it has no medical school:

"Doctors in Rhode Island often deplore the fact that we have no Medical College in the state to stimulate medical study. The awe-inspiring equipment useful in the laboratory does make an impressive sight. A Medical College, however, means medical students and they mean considerable time both from practice and research.

We are just as able to record careful histories and good physical examinations as doctors in a medical center. We can review any series of these carefully recorded cases we wish or have the initiative to study. We can be assured that such a review will always teach us something new, something that we have never read in a text book, and we will find something that will greatly help others, even those in medical centers."

SARATOGA GEYSER

Distinctly Alkaline
Naturally Carbonated

STATE OWNED AND STATE BOTTLED

SARATOGA Geyser water, because of its distinctly alkaline nature, makes an excellent natural antiacid. It has been successfully used as an aid in the treatment of patients suffering from acid dyspepsia, hyperacidity, the acidosis accompanying gout, rheumatism, neuritis and diabetes. Because of the sodium chlorid in Saratoga Geyser, it is not recommended for patients with nephritis.

Saratoga Geyser is bottled by the State just as it flows from the ground, retaining its natural mineral content, carbonization and catalytic activity. Nothing is added or subtracted.

Upon written request, we will gladly send a complete analysis and a complimentary carton of Saratoga mineral waters, including 2 bottles of Geyser and 1 bottle each of Hathorn and Coesa.

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three cents each for additional words.

FOR RENT: Office, best location. Adjoins office general practitioner. Fine opportunity for Eye, Ear, Nose and Throat Specialist. No competition. Former tenant made money. Left on account of illness. Write—S. G. Gianakoures, 19 Washington Avenue, Endicott, N. Y.

LOCATE in the heart of Queens County where population, now 1,100,000, has doubled in last decade. Near three hospitals, all transit. Colonial brick house, 8 rooms, 2 baths, on quiet street for sale. Suitable home or office. Reasonable. Owner, 78 Middletown Street, Jamaica, N. Y. C. Phone JAm. 6-6113.

SANATORIUM, NEW JERSEY SELL OR LEASE

Beautiful 20-room house, 5 minutes drive from 125th Street Ferry; in quiet, restful section, on high ground, 4/5 acre plot, overlooking Hudson. Rooms large, cheerful, airy. Hot water heating system; 6 baths, sun porches, gardens and 4 garages. Write—Box 487, Edgewater, N. J.

UNUSUAL OPPORTUNITY for physician with particular deftness in surgery to locate in very advantageous offices and take over an established and lucrative general practice, located in central New York with modern hospital connections possible. Write in detail of yourself, training and practice to date. Address Box 37, New York State Journal of Medicine.

SARATOGA SPRINGS COMMISSION

Dr. Walter S. McClellan, medical director of the Saratoga Springs Commission of the State of New York, sailed September 22 for six months study and research in Europe. In London he will be in conference with Dr. Fortesque Fox and Dr. W. S. C. Copeman, of the International Society of Medical Hydrology.

The summer season which has just closed at Saratoga Springs was marked by an unexpectedly small decline in the patronage of the State-owned spa. Reports to Chairman Pierpont B. Noyes show that from May 16 to August 31 the whole number of treatments given was 71,695, approximately 80 per cent of the treatments given during the corresponding period last year. Of these treatments 15,425 were free.

"This proportion is higher than it has ever been before," Chairman Noyes says, "and it is higher than we shall be justified in reaching again except under such conditions as existed this year. We believed, however, that it was a proper contribution for the State to make to the well being of its people."

Nearly 90 per cent of the treatments given were the mineral water baths, including the cardiac therapy which has been so highly developed at Saratoga. The whole number of these was 61,862. See page xix.—Adv.

FOR NERVOUS and MENTAL DISEASES

G. H. GEROW, M.D., *Physician in Charge.* Located in an attractive private park on the Boston Post Road. Modern equipment. Adequate personnel and classification.

DEPENDABLE SANDALWOOD OIL THERAPY

The importance of sandalwood oil in the systemic treatment of gonorrhea and its complications and in other acute infections of the genito-urinary tract is stressed by many authorities on urology. There is, however, one rather serious objection to the use of sandalwood oil therapy: it is unreliable and uncertain in its action. This arises from the fact that it is not a uniform product. The percentage of its active principle, sesquiterpenic alcohol ($C_{15}H_{22}O$) may vary considerably in different lots of the oil. The efficiency of any sandalwood oil is directly proportional to its sesquiterpenic alcohol content.

The uncertainty and unreliability of sandalwood oil therapy are eliminated when Arheol Astier is used. For Arheol Astier is all sesquiterpenic alcohol, the active principle of sandalwood oil, containing never less than 98% of santalol. It may be prescribed to meet all the therapeutic indications for sandalwood oil. Being free of the therapeutically inert but irritating substances found in even the best grade of crude sandalwood oil, Arheol Astier may be administered in full therapeutic doses without causing urinary or gastro-intestinal disturbance.

The action of Arheol Astier in gonorrhea and other conditions is described on the back cover of this issue. See page xxiv.—Adv.

ORAL THERAPY IN CONGENITAL SYPHILIS

The use of Stovarsol in congenital syphilis by pediatricians abroad induced Maxwell and Glaser to investigate the value of the therapy. The results achieved in ten cases are reported in full in the *Am. J. Dis. Child.* 43:1461-1489, June 1932.

In four cases the Wassermann reactions were negative when treatment was begun but as the parents were 4+ treatment was not delayed. These cases had remained negative over a period of thirteen months when reported. The other six cases had positive Wassermann reactions. Three were reversed after the first course of treatment, two at the end of the first rest period, and the other at the end of the second course of Stovarsol therapy. The results in these infants, all under one year of age when treatment was begun, are encouraging. Children over one year

of age did not respond so readily. Other advantageous features of Stovarsol therapy in congenital syphilis in infants and children as reported are: the remedy is administered by mouth, and the patients generally show improvement in appetite, general vigor and energy.

The authors believe that Stovarsol has a definite place in the treatment for congenital syphilis. Administration must always be under the direction of the physician as toxic symptoms may appear. In the majority of cases these symptoms are evidently mild in character but occasionally they may be severe.

Stovarsol is a pentavalent arsenic preparation allied to arsphenamine in its chemical constitution. It is manufactured in this Country by Messrs. Merck & Co. Inc., of Rahway, N. J.—See page iv.—Adv.

COCOMALT USED IN CLINICAL TESTS

Important clinical tests with Cocomalt are being conducted all over the country. Whole groups of undernourished children show substantial gains in weight after taking this food-drink regularly. During the recent drought in Arkansas, for example, health officers fed Cocomalt to youngsters for 40 days. At the end of that time, gains of from 4 to 16 pounds were noted (depending largely on age). The average gain for the 40-day period was 8½ pounds—more than a pound a week. Children who missed the Cocomalt clinic or attended irregularly showed no substantial gain. Cocomalt is a delicious chocolate flavor food-drink that is almost twice as nourishing as plain milk, adding 110 extra calories to every glass. It contains 30 steenbock (300 ADMA) units of vitamin D per ounce—the quantity recommended for one drink. Samples sent to physicians on request. Write to R. B. Davis Co., Hoboken, N. J. See page xiii.—Adv.

ERYSIPELAS

The recent reports by Symmers and Lewis of Bellevue Hospital covering the results following the employment of Erysipelas Antitoxin are most gratifying. These results are based upon the treatment of three thousand three hundred cases.

The season when erysipelas causes disability is close at hand, and physicians should be acquainted with this development and the results following the use of the product of the LEDERLE LABORATORIES.

Full information will gladly be supplied by communicating with them at 511 Fifth Avenue, New York City. See page vii.—Adv.

END RESULTS IN HYPERTHYROIDISM*

By FRANK H. LAHEY, M.D., BOSTON, MASS.

THE end results in the treatment of hyperthyroidism are intimately related to the matter of diagnosis. Some of the good results obtained by unconventional methods of treating this disease are at times undoubtedly due to treating purely neurotic states under the incorrect assumption that they are cases of hyperthyroidism, and some of the worst results with the most conventional form of treatment, surgery, are undoubtedly due to operating upon patients whose symptoms are purely neurogenic in origin, with the incorrect assumption that their symptoms are attributable to pathological thyroid states.

The diagnosis of hyperthyroidism in the frank case needs little discussion. The factors influencing the decision for or against hyperthyroidism in the borderline case are of the utmost importance.

There are occasional exceptions to the dictum which we have repeatedly stated. "No preoperative elevation of basal metabolism, no hyperthyroidism, no operation. Failure to restore the basal metabolism to normal rate postoperatively, no cure, further operation." But they are rare, and we believe that violations of the above dictum in any considerable numbers will show a high percentage of error in diagnosis and end results.

The interpretation of basal metabolism readings as related to the entire clinical picture often makes it possible to attach proper values to that individual factor. For example, given a patient on whom a basal metabolism reading of plus fifty-five is reported, but the patient is a borderline case and lacks the frank signs of hyperthyroidism, one depreciates considerably the worth and dependability of a basal metabolism reading of plus fifty-five. If this were a true report of the degree of metabolic activity, there could hardly fail to be present enough of the striking clinical features of hyperthyroidism to make the clinical diagnosis certain. One should, therefore, be skeptical of high basal metabolism in the absence of convincing clinical evidence of hyperthyroidism.

Variations in basal metabolism readings defi-

nately depreciate the value of such readings. In a series of basal metabolism tests done over three to four days, a report of plus thirty-five or plus forty on the first day, one of plus six or plus ten on the second day, and plus thirty on the third day should make us doubtful as to the correctness of the basal metabolism reports. Basal metabolism readings which are on one day normal and within a few days markedly elevated are to be viewed with suspicion as to their probable correctness.

With certain reservations, in the patients with primary hyperthyroidism in contradistinction to toxic adenomata, the consistency of the gland is of diagnostic value in the borderline case. Rarely in the presence of a true hyperthyroidism will a considerable degree of hyperplasia in the gland be absent, and so rarely in true hyperthyroidism will definite firmness in the gland on palpation be absent. When, therefore, in a borderline case the gland is of normal consistency and size (this is less dependable), one should be suspicious that the symptoms are neurogenic and not of thyroid origin. The exceptions to the above are that very occasionally thyroid overactivity of the primary type can exist in the presence of a relatively soft thyroid gland, and, on the other hand, the not infrequent occurrence of mild thyroiditis produces such a firm gland that it closely simulates in consistency that of the gland associated with primary hyperthyroidism.

The value of the eye signs of hyperthyroidism in borderline cases is not great, since when obvious eye signs are present, other convincing clinical features of the disease are rarely lacking. One early and somewhat intangible eye sign which is of value in the borderline case is swelling or puffiness of the lids, particularly of the upper lids. This swelling is not cedematous in character. It does not pit upon pressure, and later in the disease, if the disease becomes more intense, this puffiness becomes more marked and extends to the lower lids.

Of all the clinical signs of thyroid toxicity, its effect upon the pulse rate is the most characteristic. The rapid rate which is so constantly associated with true toxicity and the at least relative

* Read before the American Association for the Study of Goitre, June 16, 1932, at Hamilton, Ontario.

association of elevation of rate with degree of toxicity make this clinical feature of hyperthyroidism not only a diagnostic one but in a measure also an indication of the severity of the disease. Even with the apathetic type of hyperthyroidism in mind, of which I will speak later, in borderline cases of doubtful hyperthyroidism the absence of tachycardia of rates above one hundred with the patient up and about should make one very suspicious that hyperthyroidism is not present.

We have from time to time discussed and written about a type of hyperthyroidism which we have termed apathetic hyperthyroidism. We have now recognized and dealt with so many patients with this type of hyperthyroidism that we realize that it lacks many of the striking features of the activated type of the disease and that it can be, and is frequently, overlooked and remains undiagnosed for many months. Illustrations I and II.

Apathetic hyperthyroidism is so constantly associated with advanced years that one should always have in mind that while hyperthyroidism of the typical activated type can and does occur in people of advanced years, the apathetic type of hyperthyroidism is to be suspected in any elderly patient with persistent weight loss and persistent even though moderate pulse elevation, no matter how lacking the patient may be in the striking signs of hyperthyroidism.

A short review and comparison of some of the clinical features of this condition with those of activated hyperthyroidism will be of value as we discuss this thyroid state.

The apathetic type of hyperthyroidism occurs almost exclusively in the elderly. Activated hyperthyroidism tends to occur in the young and middle-aged. Eye signs are for the most part entirely absent in apathetic hyperthyroidism, the eyes being in quiet repose. The gland in apathetic hyperthyroidism is usually small but quite firm and pebbly in consistency. The pulse rate is persistently but not markedly elevated. The apex beat is not forceful. The pulse is not of the toxic character which one sees with activated hyperthyroidism. Gradual but persistent weight loss, often of large amounts, fifty to seventy pounds, over a period of several months, is usually a striking feature of the disease. The skin, in contradistinction to the warm, moist, velvety skin of the patient with activated hyperthyroidism, is cool, wrinkled and pigmented. These patients lack almost utterly the motor and mental activation which is so characteristically associated with activated hyperthyroidism. The basal metabolism rates in patients with this type of hyperthyroidism tend to be relatively low, plus thirty, plus thirty-five, plus forty and the reaction of these individuals to trauma, particularly in the form of operation, is strikingly different from that of pa-

tients with the activated type of hyperthyroidism. Patients with apathetic hyperthyroidism sometimes maintain pulse rates of not over one hundred and twenty during anaesthesia and subtotal thyroidectomy, only to return to their rooms, never awaken from their anaesthetic, and die in spite of all measures to improve them. Patients with apathetic hyperthyroidism die after thyroid operations quite differently than do those with activated hyperthyroidism. When a postoperative fatality occurs in apathetic hyperthyroidism, the patient, instead of being wildly activated on return to her room as is the case with typical hyperthyroidism, sinks into a peaceful apathetic unconsciousness from which she cannot be roused, and quietly dies in spite of all measures to support and rouse her. On obtaining relief from hyperthyroidism of this type, the pigmentation disappears, weight and strength are regained, and the sluggish apathy is lost. One should have in mind always that this is the type of hyperthyroidism in which unexpected fatalities occur. It is in patients with this type of hyperthyroidism that, because of the lack preoperatively of striking signs of typical (activated) hyperthyroidism and danger signs during the operation patients are often unwisely submitted to complete subtotal thyroidectomies, only to return to their rooms, never awaken from their anesthetics and die in apathetic coma. It is in cases with hyperthyroidism of this atypical type that we must be on our guard against doing too much surgery at one sitting, if we wish to avoid the definite and real mortality associated with this group of patients.

One of the most important decisions in dealing with patients with hyperthyroidism is the estimation of the degree of operative risk. Nothing has more to do with the end results than does this decision, since mortality rate is so dependent upon the correctness or incorrectness of the risk grading. It has for several years been our custom to record on the chart of each patient with hyperthyroidism at the time when the patient is first examined in the Clinic, our impression as to whether or not she will require operation in one or more stages. If this is done at the time of the first examination, the risk estimation will be made when one may be certain that the patient is seen when the evidences of her toxicity will be most obvious and so the examiner's estimate of the degree of risk the worst. Following rest in bed, a high carbohydrate diet and Lugol's Solution for a week or ten days, there may be such a striking change in the general picture of the hyperthyroidism that the recollection is apt to fade that not over seven to eight days before this same patient was considered a very serious risk. If this fact is recorded upon the chart in a prominent and constant place, and every chart is read before every operation by the operating

surgeon, the assistant and the anesthetist, this fact will occupy a prominent part in everyone's mind. Should the patient do badly in any way while on the operating table, this will serve to remind everyone that one week previously it was thought that, for example, the patient would require a two-stage operation. When it is recorded upon the patient's chart at the time of the first examination that he or she will probably require more than a single stage operative procedure, the burden of the decision of risk is on those who

a clinic where patients with hyperthyroidism are operated upon in large numbers, prove that this arbitrary grouping of risks is of distinct value.

I cannot discuss preoperative decisions as to mortality risk without mentioning also the need of the preoperative recognition of the mortality factors which Dr. Clute has called attention to, based upon a study of our fatalities. He has demonstrated that in patients who have had hyperthyroidism for over a year, there is a definitely increased operative risk. In patients who are over fifty years of age with hyperthyroidism there is also an increased risk, and in patients who have lost more than fifty pounds in weight there is a definitely increased operative risk.

Based upon an operative experience now with several thousand thyroid operations, I would like to leave this part of the subject with the following advice to any surgeons who are ambitious to do thyroid surgery. Patients with definite and intense hyperthyroidism react definitely in proportion to the degree of load that is put upon them by the anesthesia and a surgical operation or any other physical or emotional burden which they must bear. One half of a complete subtotal thyroidectomy is easier for a patient to endure than is a complete subtotal thyroidectomy. If there is any doubt or uncertainty as to a patient's ability to withstand a one stage procedure, select for her the two or even three stage operation. If one is to err in the matter of too much or too

FIGURE 1

In atypical case of apathetic hyperthyroidism. Note the wrinkled skin, the somewhat senile appearance, the extreme weight loss, lack of eye signs, lack of activation, lack of thyroid enlargement and the least suggestion of apathy.

in spite of this and after rest and preparation decide upon a one stage procedure. With the original opinion recorded at the time of the first examination that the patient will require a two-stage operative procedure, no matter how marked his or her improvement under preoperative preparation, one can be certain that this decision will be of a conservative character.

In the routine of operating upon a good many cases, as an additional measure of safety, against overlooking bad but not obvious risk cases, we have arbitrarily graded all patients at the time of the first examination into Grades I, II, III, and IV risks.—Grade I being a perfect risk, Grade II a slightly doubtful risk, Grade III a dangerous risk, and Grade IV a risk in which a fatality will occur if an operation is done upon the patient.

This plan serves also to call attention to and stress the degree of risk in bad cases, and is of real value in protecting the bad risk patient from too much surgery. The features which indicate uncertainty as to a fatality in hyperthyroidism are often so non-evident and the ease with which routine envelops and obscures these warnings in

FIGURE 2

A similar case of apathetic hyperthyroidism in which the above features are also present.

little surgery in these dangerous cases, let the decision always be on the side of safety. The

criticism for being too conservative contains no sting to the surgeon who makes the safe decision, and, with recovery, on the patient's part soon disappears and is forgotten. The criticism for a too radical decision never disappears and, unlike the above, bears the everlasting sting of being a just and deserved criticism.

TABLE I

Operative Mortality in Exophthalmic Goitre

	Cases	Operations	Deaths	Case Mortality	Op. Mortality
1927	439	596	4	.9%	.67%
1928	536	676	0	0%	0%
1929	448	539	4	.89%	.74%
1930	398	568	5	1.25%	.88%
1931	472	648	3	.63%	.46%
Total	2,293	3,027	16	.70%	.69%

Table I—Mortality is such a self-evident part in end results that anything which influences this is of extreme importance, and preoperative preparation of the toxic thyroid patient plays a very considerable part in the mortality rate. The best risk patients are those who react favorably to preoperative preparation as evidenced particularly by weight gain, also by a drop in pulse rate and basal metabolism rate. During the period of preoperative preparation, all patients are kept in bed except for an hour in the morning and afternoon, when they are encouraged to walk about. We cannot prove it, but from a comparison of the two methods, we feel sure that patients who are up and about for a short period twice a day in the period of preparation are better prepared for the operation than are those who are kept in bed all of the time.

Our average time of preoperative preparation is about eight days, but one should have no fixed rule as to this time, being covered by how sick the patients are, and continuing preoperative preparation as long as there is obvious improvement.

In the very toxic patient with vomiting and diarrhoea, the important features of the preparation are, first, that they receive sufficient fluids, and with this in mind we provide for it by giving them at least three thousand c.c.'s containing at least one hundred and twenty-five grams of glucose in twenty-four hours. In many of the patients with severe thyroid toxicity, particularly when they are vomiting, it becomes a problem to give them the necessary amount of iodine to bring about an abatement of the rising rate of intoxication. In such cases we have learned that fifty minims of Lugol's Solution may be administered in a thousand c.c.'s of salt solution at the time at which the salt solution and glucose are administered. This is in our experience the most positive and satisfactory way of employing iodine in the patient with very severe thyroid toxicity.

End results as they relate to mortality are at times attributed to the form of anaesthesia. Good

results are being obtained by various surgeons with a variety of forms of anaesthesia, and we are of the opinion that if one excludes ether as a form of anaesthesia in these cases, this feature is not as important in the outcome as we have at times considered it. Ether is in our opinion chiefly undesirable because of the fact that it produces so much nausea, and because patients are so long in coming out of it. Anything which interferes with the intake of fuel and water during the period of hypercombustion associated with severe thyroid reactions is undesirable. Of the inhalation anaesthetics, nitrous oxide or ethylene with its higher percentage of oxygen are very satisfactory. Avertin provides a highly desirable feature in the operative management of toxic patients. With its pre and postoperative period of abolished consciousness, it robs the visit to the operating room of its terror and eliminates largely the consequent psychic shock. Local anaesthesia with patients conscious and unprotected as to psychic shock either by light nitrous oxide or avertin is, in our opinion, an unnecessarily trying emotional ordeal, and one which, at least in some moderate measure, places an unnecessary burden upon an already overburdened individual.

In any well organized clinic where thyroid surgery is being done in any considerable amount, the very low mortality rate which exists in these clinics is made up, at least in a considerable part, of technical accidents and postoperative complications. With this in mind, we wish to state that there is a tendency, particularly on the part of surgeons who devote themselves largely to goitre surgery, to become oversentimental as to the length of the incision and oversentimental as to the preservation of the prethyroid muscles. We feel very strongly that any good fortune that we have had as relates to postoperative complications (we have had four patients with complete tetany and never a complete bilateral nerve injury in now very close to eleven thousand thyroid operations) is in a large measure due to the wide exposure which can be obtained with a generous incision, with the prethyroid muscles cut, a dry field and anatomical exposure of the entire gland and the anatomical structures to be avoided.

The immediate control of bleeding in thyroidectomy is not only necessary if one wishes to do accurate anatomical dissections of the gland, but the control of bleeding so that secondary hemorrhages do not occur later is of very great importance. It is not the bleeding of secondary hemorrhage itself, although patients with severe thyroid toxicity stand blood loss badly, which is of the most importance. It is the fact that secondary hemorrhage, when it happens, occurs either on the afternoon or evening of the day of operation or on the first or second postoperative days. The most unhappy feature of this situation is that patients at this time show their greatest degree of thyroid reaction to the operative

procedure, and must then be taken to the operating room or anesthetized in bed and put through another emotional ordeal, which in serious risks may well be the factor which brings about a fatality.

We feel very strongly that the control of blood supply, particularly in operations upon patients with toxicity, should be undertaken with the idea in mind that precautions are being taken against possible secondary hemorrhages and their possibility of increasing mortality rate.

Exposure is a basic principle in surgery and this principle is as applicable to thyroid surgery as it is to abdominal surgery. A scar on the neck is a scar, and whether it be an inch or two or even three or four longer or shorter makes but little difference in its appearance, but often makes a great difference in the ease and safety of the operation. We have literally cut thousands of prethyroid muscles. In two-stage operations we have cut muscles on one side, sutured them, and had the opportunity to observe the point of suture and the muscle itself at the second-stage procedure on the opposite side in at least hundreds of cases. As the result of this experience, we know that if one cuts muscles high and sutures them with reasonable care, there is no muscle atrophy, they heal so that one cannot tell the cut from the uncut side, and there is nothing relating to function which is lost in these cases. We urge strongly, as the result of our experience, that you do not incite in patients that pride in a short incision for their goitre which was a blot on surgery when applied to appendectomy. What a criticism of our common sense and judgment it was when surgeons were famous for the shortness of their appendectomy incisions. Do not operate upon patients for goitre unless they need it, and then get an exposure which permits you to visualize the entire gland and its important adjacent anatomy. We have no hesitancy in cutting the prethyroid muscles. We make it a practice to cut muscles in all toxic cases and in many of the non-toxic cases. We believe that with the muscles cut we can get better exposures, and what we can see we can avoid.

The end results in thyroid surgery, particularly that of thyroid toxicity, are inevitably associated with the matter of technic, especially as related to the amount of thyroid tissue removed and surgical accidents or errors of a technical character. We have recently published in the *Annals of Surgery** our views regarding the varying amount of thyroid tissue to be removed in patients with various types of thyroid toxicity, and I do not need to again discuss that matter. A point which was made in that article and which is, I believe, of very great importance in bringing about satisfactory end results in these cases is

*"How Much Thyroid Tissue Should Be Removed in Toxic Goitre?" *Annals of Surgery*, April, 1932, Volume XCV, No. 4, pp. 529-536.

the complete removal of the thyroid isthmus, together with any pyramidal lobes. If you will look at the diagrammatic illustrations III and IV, you can at once see, I believe, that with isthmus removal a larger segment of thyroid tissue can be removed with good sized thyroid remnants left over the region of the recurrent laryngeal nerve and parathyroid bodies than can be removed, if an attempt is made to leave a section of thyroid tissue on the trachea in order to protect it from trauma and the possible tracheitis which is assumed to follow it. We have now removed the isthmus completely in all patients with toxic goitre for several years and feel sure that one does not need to fear that it increases the amount of postoperative tracheitis or produces any other undesirable complication.

With good exposure, accurate control of bleed-

FIGURE 3

This shows diagrammatically the result of completely baring the trachea. Note the two segments of thyroid on either side and more than half of the trachea bared.

ing and turning of the cut surfaces of the gland against the trachea by suture as we have advocated for a number of years (Illustration V), the institution of drainage is rarely necessary. We feel quite sure that with bleeding well controlled there is no more postoperative reaction in the undrained case than in the drained case.

We feel very strongly that the surgical error of removal of parathyroid bodies is largely due to lack of exposure and to lack of control of bleeding, as already stated, but because of the fact that thyroid bodies are not infrequently atypically located (we have seen them on the front of the gland, embedded in the gland, and separate and at some distance from the gland), they will occasionally be removed in spite of meticulous pains to avoid them. Since the demonstration by Halstead and the further demon-

FIGURE 4

This shows the method of removing one lobe and the isthmus at a first-stage subtotal hemithyroidectomy. Attention is called to the fact that when a thyroid operation is divided into two stages, the second-stage is made much easier by the removal of the isthmus together with the lobe at the first-stage. Note how completely this bares the trachea and the large segment of tissue removed at the isthmus.

stration by Drs. Cattell and Mason in our Clinic that these glands can be successfully transplanted, we strongly urge that anyone doing thyroid surgery become familiar with the gross appearance of these bodies; that specimens be carefully searched for them, and that they be transplanted in an adjacent muscle belly at once. It is wise, we believe, to take a minute section for the pathologist from each of these bodies to be transplanted, in order that one may prove with certainty as to whether or not the body is really a parathyroid body. This is valuable also in that

one is certain or not that he has really transplanted a parathyroid, and serves also the purpose of checking one's judgment as to what is or what is not a parathyroid gland in gross appearance. We have learned in our experience when dealing with the transplantation of a large number of parathyroid bodies that if a successful graft is to be obtained, care must be taken to see that the transplant is made deep into the belly of the sterno-mastoid, which is chosen because of its convenient closeness, and because of the thickness of its belly, and care must be taken also to see that the transplant is made into a dry pocket. Transplants made into pockets filled with blood will be macerated, digested, and will fail to take and function.

We have discussed up to now the factors which influence the end results, largely in terms of mortality and I wish to present to you now some actual end results, first in the form of a large group of metabolism examinations at the end of a year, Table II, in which there is a considerable defect because a large number of the patients upon whom the original metabolisms were done, did not return at the end of a year for their follow-up metabolism. The absence of such a large percentage of the original one thousand cases, as

FIGURE 5

By turning the remnant of the gland in against the trachea and suturing it to the first fascia of the trachea, it is possible to so reconstruct the gland that no oozing occurs and thyroid wounds can thus be sewed up without drainage.

Notice the complete baring of the trachea in both cases and the restoration of the isthmus in b.

reported here, largely invalidates the reliability of these figures.

In Table III we find the preoperative and the postoperative metabolic rate determinations in one hundred and eighty-eight cases in which the metabolism was done before operation, after operation and again at the end of a year. These figures are more valid in that every case reported at the end of a year for a follow-up report and the average basal rate at the end of one year, actually represents the end results in the same one hundred and eighty-eight cases. These fol-

TABLE II

This table was published in the *American Journal of Medical Sciences*, July, 1928, No. 1, Vol. clxxvi, pl. showing end results as related to basal metabolism and weight gain and may be criticized, as stated in the text, because of the fact that such a large number of patients failed to report for final check-up metabolism at the end of a year

Lahey Clinic	Primary		Secondary	
	No of Cases	Average	No of Cases	Average
B M R Before operation	1,000	+49.38	245	+40.94
B M R 8 days after operation . . .	1,000	+20.48	245	+22.27
B M R 12 mos after operation .	380	+ 2.34	38	+ 2.63
Gain in weight from weight after operation:				
3 mos after operation	850	15.35 lbs	123	1.26 lbs
6 mos. after operation	652	20.43 lbs	81	7.56 lbs
9 mos after operation	424	22.74 lbs	40	9.43 lbs
12 mos after operation	380	24.37 lbs	38	13.51 lbs

low-up figures lack value in that they report end results solely in terms of a laboratory finding.

At the recent meeting of the American Medical Association, Dr. H. M. Clute and Dr. J. R. Veal of the Clinic, reported on the end results of the surgery of exophthalmic goitre on ninety-seven patients followed by basal metabolism studies and clinical examinations, all of whom had been operated upon five years or over. These figures are dependable in that they are not reports by mail. They have been checked by personal examination of every patient on the part of Dr. Clute or Dr. Veal and every patient has had a basal metabolism examination at least five years after the original operation. In addition to that, the percentage of patients who have myxoedema is reported, the percentage of patients who have persistent and recurrent hyperthyroidism is reported, the percentage of patients in which any degree of tetany occurred is reported and the percentage of patients in whom recurrent laryngeal injury occurred is also reported.

Dr. Clute and Dr. Veal sent letters to one hundred and eighty-six consecutive patients with exophthalmic goitres who had been operated upon five or more years previously. Of these, they were unable to locate fifty-six but succeeded in following one hundred and thirty patients operated on for exophthalmic goitre of over five years standing. In twenty-six cases, the only information received was by letter and this was, therefore, discarded. In seven cases, then information was determined by personal examination but they were unable to secure metabolism tests on these patients and they were, therefore, also discarded. They personally did clinical examinations and obtained metabolism reports in our own laboratory on ninety-seven consecutive cases which represent a five-year follow-up on this group of cases.

The average basal metabolic rate for this entire group of patients at entrance in the hospital was plus fifty-four. After these patients had

been prepared for operation with Lugol's Solution and test, a subtotal thyroidectomy was performed. In thirty-five per cent of the cases it was necessary,—or considered wise—to do this in the form of divided operations. The average metabolic rate of these ninety-seven cases just before leaving the hospital, that is, just before

TABLE III

This table is of greater value than Table I since every patient had a metabolism before operation, after operation and at the end of a year. It may be criticized, however, as stated in the text, because of the fact that it reports end results solely in terms of metabolism for which reason the end results as obtained by Dr. Clute and Dr. Veal from ninety-seven cases followed in the Clinic as stated in the following paragraph at the end of five years, are of much greater value.

188 Cases of Primary Hyperthyroidism Showing Variation in B M R From Before Operation to 12 Months After Operation

B M R Before Op 188 Cases	B M R After Op 188 Cases	B M R 3rd Mo After Op 173 Cases	B M R 6th Mo 169 Cases	B M R 9th Mo 137 Cases	B M R 12th Mo 188 Cases
+39	+15	+7	+2	+1	-3
Gain in Wt 14 lbs			4 lbs	2 lbs	3 lbs

discharge, was plus fifteen. Ninety-three of this group of patients were followed post-operatively with metabolic estimations and clinical examinations at intervals of six months to a year and the average metabolic rate in these ninety-three patients was minus one. Final check-up examination was made on the entire ninety-seven cases, five or six years after operation, and showed the average basal rate for the entire group to be minus one.

As an additional check on the end results in these ninety-seven cases, Dr. Clute and Dr. Veal found it interesting to note that the average resting pulse rate at the time of entrance for the metabolism test was one hundred and eight. Following operation the average pulse rate before leaving the hospital in the ninety-seven cases, was eighty-five. At the time the patients returned—six months to one year after operation—for their post-operative metabolism test, the up and about pulse rate in ninety-three cases was seventy-two. In the final metabolism test done five years after operation in this study in which the pulse rate was known in ninety-six cases, the average pulse rate was seventy six.

In ninety-six of these cases, the average weight on admission was one hundred and nineteen pounds. The average weight of ninety-two of these patients taken six months to a year after operation had increased to one hundred and thirty nine pounds, and in the ninety-six cases in whom the weight was listed five to six years after operation, the average was one hundred and forty-three pounds, showing an average gain per individual in this group over a period of five to six years of twenty-four pounds. The end results as relates to exophthalmos are also of in-

terest. In one hundred consecutive patients examined in 1926, sixty-two cases were noticed as having definite exophthalmos preoperatively, an incidence of sixty-two per cent. Twenty-one of these same one hundred patients showed exophthalmos five years later.

As to the incidence of myxœdema in this group of ninety-seven patients, myxœdema occurred three times as a persistent condition which is still present and requires treatment. All three patients with myxœdema are well but require thyroid feeding. Four patients in the group had quite low basal rates at the end of three months following the operation when their first post-operative basal metabolism tests were done, but all have now returned to normal basal rates and none of them require thyroid feeding.

In this group of ninety-seven cases, six can be classed as persistent hyperthyroidism and six others as recurrent hyperthyroidism. Of the group of six with persistent hyperthyroidism, four required later operation and of these one only was cured. Two of these four are still toxic but their symptoms are controlled with Lugol's Solution and they are able to live normal lives. One of the four patients with persistent hyperthyroidism, a patient with established auricular fibrillation for five years, died of an embolus eight days following a recent secondary operation on her thyroid. The remaining two of these six cases of persistent hyperthyroidism are still mildly toxic but are adequately controlled with Lugol's Solution. In the six cases with recurrent hyperthyroidism, two required later operation. One of these two has remained perfectly well with normal metabolism for three years. The other one was operated upon too recently to report on. The remaining four cases with recurrence of their hyperthyroidism are all of the mild type and are adequately controlled with Lugol's Solution.

Injury to both recurrent laryngeal nerves has occurred but once in our entire experience now

with something between ten and eleven thousand goitre operations. We have had occasional injuries to the single recurrent laryngeal nerve but they have never been of any serious consequence.

As relates to injuries to the parathyroid bodies, and the onset of tetany in this entire experience with goitre operations, complete tetany has occurred but three times and transient tetany eleven times in our entire experience. One case of transient tetany occurred in the group of patients reported here, a patient operated in 1926. This patient was re-examined lately and found to have no evidence of tetany and required no treatment for the condition.

As relates to the ultimate effect of subtotal thyroidectomy, in all the group of one hundred and thirty-four patients followed by mail and also by personal examination, it was found that in the five to six-year interval since the time of operation, four had died. Of these four, two died of pneumonia at intervals of two and three years after their operation. One died of cancer of the pancreas some months after the thyroid operation and one died of nephritis four and one-half years after operation. Dr. Clute summarizes the results obtained in the follow-up of these ninety-seven patients who had been operated on for hyperthyroidism five years or more, saying that in eighty-two cases, complete cures were obtained. In seven other patients, there is still slight toxicity present entirely controlled by Lugol's Solution. Three patients developed myxœdema which is entirely controlled by thyroid extract. Four patients in the group are still toxic. None of the four are in any way incapacitated and all are working. One of the patients in the group died following a recent secondary operation for recurrent hyperthyroidism and congestive heart failure. It is, therefore, possible to say that ninety-two or ninety-four and eight-tenths per cent of these ninety-seven cases were relieved of their symptoms of this disease by subtotal thyroidectomy.

EPIDEMIOLOGY OF SEPTIC SORE THROAT*

By PAUL B. BROOKS, M.D., DEPUTY STATE HEALTH COMMISSIONER,
ALBANY, N. Y.

SEVENTEEN years ago Dr. Hermann M. Biggs, in a paper on the topic "Milkborne Septic Sore Throat—A New Health Problem,"¹ said:

"Septic sore throat, while probably not a new disease, has at least appeared in a previously unrecognized form in this country within the past few years. A number of extensive epidemics have occurred, all resembling each other closely

in character and due as a rule primarily to widespread milk infections."

No such milkborne epidemics had been reported in this country, he said, previous to the Boston epidemic of 1,400 cases in 1911, although they had not been uncommon in Great Britain, where one had been reported as early as 1875. He then discussed several American epidemics and said that three of serious extent and several smaller ones had occurred in New York State in a little over a year.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

Our records of milkborne outbreaks of this and other diseases in this State, exclusive of New York City, from January 1, 1917, to date, show none of septic sore throat until 1925, an extensive epidemic in that year, a lapse of three years and three outbreaks annually since: 10 altogether with a total of nearly 1,800 cases, all traced to raw milk, in most instances from herds in which there were cases of bovine mastitis. The total of approximately 1,400 cases in the nine outbreaks in the last three years constitutes about 85 percent of the recorded cases in this period. Except for cases which occurred in an outbreak which may have been due to contamination of ice cream by a carrier, the balance presumably were sporadic.

Dr. Bigelow,² in 1929, referred to 15 outbreaks which had occurred in Massachusetts in 18 years. The latest and most serious of these was the one at Lee in 1928, with over 900 cases and 48 deaths occurring in a community of 400 inhabitants. Our epidemic at Walton, N. Y., a community of about the same size, in which there were 444 cases and seven deaths, was comparable although the mortality—about 2 percent—was considerably lower.

Judging from the data collected and published by the United States Public Health Service, New York State has had much more than its pro rata share of these outbreaks as compared with other states. Whether this means that infection is actually more prevalent here or that outbreaks are being overlooked elsewhere remains to be determined.

We have come to look upon septic sore throat as a clinical entity. Certainly in typical cases there is a fairly definite clinical picture. Yet individual cases vary greatly and so far as the physical signs in the throat are concerned there is little if anything to distinguish infections with different strains of virulent hemolytic streptococci. Dr. May Holmes,³ describing cases seen during the Lee epidemic, said that "the redness was not as sharply circumscribed as in scarlet fever." Ordinarily, however, there seems to be nothing characteristically different in the throats in scarlet fever and septic sore throat.

Dr. D. J. Davis of Chicago, some years ago gave the name "Streptococcus epidemicus" to a type of hemolytic streptococcus which he considered the specific incitant of this disease. In addition to certain cultural peculiarities which he described, he considered its outstanding characteristic to be a well defined capsule observable in moist india ink preparations. Other distinguished observers support his position as to the identity and specificity of the organism. In our laboratory, where extensive studies have also been made, organisms meeting the "epidemicus" specifications have been obtained from cases of scarlet fever and erysipelas and from normal throats,

while those definitely known to have been responsible for certain milkborne epidemics have not conformed. Cultures from one of these epidemics were sent to one of the active proponents of the identity of the organism and he is said to have reported that in his opinion the streptococcus on the cultures was not "epidemicus." The present conclusion in our laboratory is that there is as yet no known method by which a specific excitant of this disease can be identified, and Dr. Park of New York and Dr. Breed of Geneva seem to have reached the same conclusion. While still looking for the "epidemicus" characteristics we are satisfied, for the present epidemiologically, if we find hemolytic streptococci with identical morphology, cultural and biochemical reactions in the human cases and in the milk or discharge from the cow's udder. Irrespective of the merits of the question of identity of the organism it certainly is not yet safe, in epidemics or clinical cases, to disregard organisms found because they do not conform to "epidemicus" specifications.

Dr. Biggs⁴ described an epidemic which occurred in Poughkeepsie and vicinity in 1915 in which there were at the same time 212 cases of scarlet fever and 296 of "sore throat." In one of our more recent outbreaks cases of both diseases were reported. It is also well known that cases of erysipelas frequently occur in connection with milkborne septic sore throat epidemics. In an epidemic of 487 cases at Portland, Oregon, in 1923,⁵ twenty cases of erysipelas occurred. This condition was observed in two of the fatal cases at Walton.

Dr. Biggs, referring to the Poughkeepsie epidemic, said:

"There are three possible assumptions in connection with this outbreak; the first—that an epidemic of scarlet fever and an epidemic of septic sore throat occurred at the same time, both probably the result primarily of milk infections. The second—that this whole outbreak was one of septic sore throat of unusual severity; and the third—that this was an epidemic of scarlet fever throughout, and that the sore throats were simply mild types of scarlet fever in which the eruption was not recognized or was transient, or was absent entirely as is sometimes the case." A fourth possible assumption might be added: that scarlet fever, septic sore throat and possibly also erysipelas are simply different manifestations of the same infection, the determination as to the character of the manifestations depending on conditions, not yet understood, affecting the organism. The experience in an epidemic which occurred at Kirkland Lake, Ontario, in 1930,⁶ is interesting in this connection. There 11.8 percent of the patients gave a history of having had scarlet fever and several were convalescing from that disease when taken with septic sore throat.

Epidemics of septic sore throat believed to

have been primarily due to contact have been reported, and scattered cases apparently due to contact usually precede and follow milkborne outbreaks. Most outbreaks of this disease, however, are primarily milkborne and our recent experience and observation convince us that extensive milkborne outbreaks rarely, if ever, occur except when cases of bovine mastitis are involved. Where the cow is missed it is convenient to fall back on the carrier; but it seems very improbable that accidental contamination of milk by a carrier would account for an extensive outbreak extending over days or weeks, especially as there seems to be a tendency for the organisms to die out after a few hours in milk which has been properly cooled.

Mastitis among cattle is extremely common and ordinarily caused by a streptococcus not usually pathogenic for man. Apparently it is only on the relatively rare occasions when the udders, perhaps already damaged, become infected with organisms from human cases or carriers that the cases of mastitis become responsible for epidemics. It is not unusual to obtain histories of the occurrence of cases among milkers preceding epidemics and carriers may be found, but for obvious reasons it is usually difficult to determine definitely just how the cow became infected. In several of our outbreaks there have been histories of injuries to teats or udders. In one the dairyman had on his arm a suppurating wound discharging streptococci identical with those found in the cow and in the human cases of septic sore throat.

Bigelow⁷ relates an interesting experience in connection with the Lee epidemic. A cow was found which was discharging "*S. epidemicus*." On the farm there was a child which had had sore throat and from whose throat hemolytic streptococci were obtained which, however, did not correspond to those obtained from the cow. A presumably normal quarter of a healthy cow was infected experimentally with the organisms obtained from the child; the infection persisted for two months and led to mastitis but "the organism remained true to type and developed no new characters that would ally it with the organism associated with the epidemic." Once implanted the organisms multiply rapidly and for a time are discharged in large numbers. They usually disappear after a time from the originally infected quarters and may later be found in apparently normal quarters. Vaughan⁸ suggested the possibility that the virulence of the human strain of organisms might be greatly increased by passage through the udder.

I have recently studied the age and sex incidence of 981 cases occurring in three of our epidemics: Walton, Saugerties and Savannah. Both conformed to the usual observations in milkborne epidemics of this disease. Seventy-seven percent

of the cases were in persons over 15 years of age and there were very few under 5. As usual the deaths were mostly among persons past middle age. The percentage of females involved was 58. Just after arriving at this figure I read in Dr. Biggs' paper⁹ the following with reference to an epidemic of 900 cases which occurred in Westchester county in 1915:

"Fifty-eight percent of the cases were among females—a peculiar incidence characteristic of this disease in almost every outbreak previously reported."

At Kirkland Lake, Ontario,¹⁰ the story was a little different. This is a mining town and males predominated both in the population and among the cases. Seventy-one percent of the cases were in persons over 15 but of those under this age 51 percent were under five.

One remarkable thing about the milkborne epidemics here and elsewhere is that many of them have been traced to exceptionally good farms. Our largest outbreak in recent years was traced to one of the best farms delivering milk to the city and to a thoroughbred cow, the best milk-producer on the farm. At Savannah samples taken from cans at the farm and examined in Dr. Breed's laboratory gave counts around 2,500. The dairy responsible for an outbreak on Long Island had an average count of 9,000.

In this rambling paper I have not attempted a comprehensive discussion of the subject but have simply tried to bring out a few of the interesting points. My study of the subject has led me to at least two definite conclusions. The first is that there is still a great deal that we do not know about streptococcus infections. The other is that unless it is possible to apply the rigid precautions against mastitis and against milk infection which are required on farms producing Certified milk, with at least equal care and supervision, the only practical safeguard against milkborne outbreaks of septic sore throat is pasteurization.

SUMMARY

Although milkborne outbreaks of septic sore throat previously were not uncommon in Europe, none were reported in this country before 1911. Several occurred in New York State in 1915. From January 1, 1917, ten have been recorded in the State, exclusive of New York City, one in 1925 and three each in 1929, 1930 and 1931. Cases in the last nine constitute about 85 percent of the recorded cases.

While septic sore throat is generally regarded as a clinical entity, the facts concerning the relationship between this and scarlet fever, erysipelas and other hemolytic streptococcus infections are not yet well understood. Competent observers are not in agreement as to the possibility of identifying a specific incitant of this disease.

While the disease may be spread by contact,

most epidemics are milkborne and cases of bovine mastitis are usually involved in extensive outbreaks. The bovine infection probably is always of human origin.

The age and sex incidence in 981 cases occurring in three New York State outbreaks con-

formed to the usual observations. Seventy-seven percent of the patients were over 15 years of age and 58 percent were females.

Milkborne outbreaks are frequently traced to exceptionally good farms. The only practical safeguard is pasteurization.

REPORT OF SEPTIC SORE THROAT OUTBREAK IN GREENWICH, WASHINGTON COUNTY, N. Y.*

By WILLIAM L. MUNSON, M.D., DISTRICT STATE HEALTH OFFICER, GRANVILLE, N. Y.

ORGANIZATION OF ADMINISTRATIVE PERSONNEL

IN doing the routine check-up on the daily card reports for May 22, 1931, I found five reports of septic sore throat in Greenwich village. I immediately telephoned the health officer and he stated to me that six other cases had just been reported to his office.

Conference was held the next morning for discussion of evidence already at hand and to determine on methods of investigation. This conference was attended by Dr. Graves and Mr. Leete of the Bureau of Milk Sanitation of the State Department of Health, Dr. Rogers, Health Officer, Misses Snyder and Mulligan, County Nurses, and myself. Arrangements were made for the nurses to immediately take cultures of the throats of those sick and to get specific epidemiological data on each clinical case. Dr. Graves and Mr. Leete immediately began a complete investigation of the herds of the farms who furnished milk to the suspected peddler.

MILK SUPPLY

The milk supply of the village of Greenwich, which has a population of 2,270, was furnished by:

1. The W Dairy, selling 580 quarts.
2. The M or W Dairy, selling 130 quarts.
3. The M Dairy, selling 375 quarts.

It had been noted that all cases reported were on the route of the W Dairy. Thus it will be seen that the immediately suspected supply furnished 580 quarts of milk out of the total, or about 53% of all milk sold in the village. Of the total cases reported all but one case was on the W's milk and that case was proved to

be a contact. It should be noted that pasteurization took place on May 23 while the peak of the outbreak occurred on the twentieth.

CASES

The cases may be divided into two groups. The first group is composed of 24 cases developing in twenty families in an explosive outbreak in May, 1931, especially on the twentieth, as shown in table one. The second group includes cases developing since May, 1931, as shown in table two. All the cases in the May explosion except six were checked by laboratory positives; and all cases since that time, except eight, had positive laboratory reports.

Day of Month	Number of Cases
12	2
13	2
14	2
17	1
19	2
20	9
21	1
23	1 Pasteurization begun
26	1 contact
28	1 contact
29	1 contact
31	1 contact
Total	24

Table 1. Number of Cases in the Explosive Outbreak in May

All of the cases during May were drinking raw milk and all but one were on the suspected route. The cases which have occurred since have been rather difficult to investigate so far as the milk supply is concerned. Just across the village line

* Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

there is a raw milk stand and it is surprising how many persons would go there for their supply, and it is also surprising the type of person that would occasionally be found. A number of cases which have occurred since and who have told the nurse that they were drinking pasteurized milk are definitely known to the health officer and me to have gone across the line for raw milk. There was one very notable case in which this occurred and it was one of the cases which had severe complications following the disease.

Total	51

Table 2. Number of Cases by Months

All the cases which occurred on May 20 were in one small group on the Hill-Bleeker section with one exception and that occurred on Whipple Place. It is fair to deduce from this set of facts that the infection was in just one can of milk which was delivered to this group of people. The dairyman says that all the milk was mixed before bottling for delivery but neither the health officer nor I believe that. It is true, too, that this section represents that center of densest population in the village.

INSPECTION OF HERDS

A complete survey was made of the herds supplying the milk to the suspected dealer by Dr. Graves and Mr. Leete. In this inspection there were hundreds of specimens examined. Finally, on the farm of one J. D. W., there was discovered a cow (No. 4064K) one quarter of which was dripping pus. Culture on May 24 from this infected teat showed hæmolytic streptococci of the same cultural and morphological characteristics as those found in the throats of those persons sick with the disease.

SOURCE OF INFECTION

It was found that the wife of the farmer had had a sore throat from which she had recovered and that on the 24th of May had a negative culture; but that the husband who was in charge of the milk supply and was doing some of the milking, showed a throat culture of hæmolytic streptococci on May 25, 1931. He had not been sick enough to take to his bed as far as we were able

to gather the history. It is interesting to note that this farmer argued that his milk could not be infected because it was his wife who had really been "quite sick" and she had nothing to do with the handling of the milk.

SEQUENCE OF EVENTS

There seems to be no question at all but probably the sequence of events was that Mrs. W had septic sore throat, that Mr. W contracted it from her and that he infected the cow by stripping the teat which was sick and that the infection from this cow was in the milk which was drunk by the persons in the outbreak.

AGE INCIDENCE

The age incidence in the cases recorded shows the largest number of cases to come in the age group 31 to 40. In the total number of cases in the explosive outbreak 10 of them occurred in this group—or about 41% of the total. Practically the same age grouping has occurred in the cases which have occurred since the May explosion as is shown in table three.

	May, 1931	June 1, 1931, to April 30, 1932
Under 11 years.....	3	5
11-20	1	7
21-30	5	5
31-40	10	9
41-50	1	1
51-60	1	0
Over 60	3	0
Totals	24	27

Table 3. Age Incidence of Septic Sore Throat Cases in Greenwich, Washington County, N. Y.

In an outbreak in Westchester County in 1915 the age incidence of 720 cases was given as follows in table 4.

Under 11 years	181
11-20	119
21-30	146
31-40	153
41-50	81
51-60	30
Over 60	14
Age not stated	181

Table 4. Age Incidence in Westchester Outbreak in 1915

It will be seen from this that the age group 31-40 had a large number of cases. Dr. Rosenau of the Harvard School of Public Health says, "Although septic sore throat is largely a milk-borne disease, the greatest prevalence is among adults and not among children who are the milk drinkers and among whom we would expect the greatest number of cases."

SEVERITY OF CASES

About half the May cases, roughly speaking, were considered severely ill, adults predominating, and about 20% developed complications. While there were no deaths some of the patients suffered very severe and crippling illnesses. One person has just returned to duty after almost a year of disability. In an article by Dr H M Biggs in the *Medical Record* of December 4, 1915, on "Milk borne Septic Sore Throat" he states "The children and young adults were not seriously ill, being confined to the house as a rule only two or three days. Those in middle and later life suffered severely, relapses and complications being of frequent occurrence." In the 27 cases since May, 1931, only two had complications and these were the only ones considered at all seriously sick.

Before the explosive occurrence of these cases in the village of Greenwich there had occurred two known cases in the rural section, about four miles from the village, in a rural settlement called "Middle Falls." There also was the occurrence of the cases of Mr and Mrs W on the dairy farm.

It is the opinion of the writer that there is constantly in most communities occurring cases of this disease and that for one reason or other they are not reported and that outbreaks occur only when the proper circumstances conducive to a large number of cases occurring are present, that is

- 1 A dairymen with the clinical disease
- 2 A cow with mastitis
- 3 The consumption of this milk raw by a large number of patrons

Following the outbreak of any communicable disease there is a distinct heightening of the diagnosis and reporting of that particular disease. Everyone becomes conscious of the disease and is on the look out for it.

Because of the discussion in the community and because of a forward looking health officer with insistence, persistence and ability kept the matter before the board of health an ordinance permitting only pasteurized milk was passed for the community. One of the outstanding features of the investigation was the complete cooperation of the health officer, Dr Rogers. It was not only in giving his consent but his active help was cardinal. He was very potent in energizing the whole investigation. Also he had backbone in pushing through when locally at times it might have seemed to his advantage to pussyfoot. As a matter of fact he gained the respect of his people more than ever by his unwillingness to weaken. I might say in passing that he has one of the largest and best practices in my district. My experience has been that the busy men—the good doctors—are really the ones to get to do things

They know how to arrange their time. God deliver us from the ones who are just getting by, that always see the bogey man and are constantly talking to ghosts.

CONCLUSIONS

1 That there was an explosive outbreak of 24 cases of septic sore throat, that the infection was conveyed by the milk of a particular dealer and that this milk was from a cow with mastitis which was infected from human sources.

2 That the epidemic served a good purpose in that it resulted in an ordinance for the sale of only pasteurized milk in the community.

3 That the way to investigate such outbreaks is by swift-moving and thorough going executive and administrative procedures.

4 That the most important part of such an investigation by the epidemiologist is his use of the intelligent and competent services of veterinarians and milk experts.

5 That where the local health officer is interested and active, things get done.

For the most part modern medical papers set up the essayist as a section of the judgment day with total disregard for the many questions which are apparent but which are failed of answer. The questions unanswered are probably more important than those which are answered.

May I not submit herewith some questions which I have not found the answer to and which suggest the need of further study?

1 Why is the age incidence so high in septic sore throat—why does not the disease occur in the milk drinking age?

2 Is the septic sore throat caused by milk routed haemolytic streptococci more virulent than the contact routed organisms?

3 Is it possible there is one type of haemolytic streptococci which humans have and which may be transmitted to the cow's udder and thereby infect the milk and another type which will cause the disease in humans by contact and yet can not be transmitted by the cow's milk?

4 Is it true that explosive milk borne septic sore throat is more apt to be severe and have complications than contact cases or the cases which are occasionally occurring?

5 Is it a fact that septic sore throat is quite a common community disease which is largely missed because of failure to take cultures and is called just plain sore throat and is only recognized when a milk-borne epidemic occurs and puts everyone on the alert for the disease?

6 Isn't it a fact that while we have done a great deal in a practical way with the epidemiology of septic sore throat there is yet plenty of need for scientific investigation and shouldn't this be done in the field with the laboratory-trained worker, the milk expert and epidemiologist working together?

THE DOG'S GIFT TO THE RELIEF OF SUFFERING

Prepared by WALTER B. CANNON, M.D. and CECIL K. DRINKER, M.D., BOSTON, MASS.

This article is reprinted from The New England Journal of Medicine of September 15, 1932, at the request of the Committee on Medical Research of the Medical Society of the State of New York. It is a revision of an article entitled "The Dog's Gift to the Relief of Human Suffering," by W. B. Cannon, and published in Hygeia of January, 1926. The revision was made necessary because of the progress in the conquest of disease achieved through the dog since 1926.

YEAR by year bills are introduced into State legislatures designed to prohibit the use of animals in scientific experiments. Year after year, physicians, members of university faculties, and enlightened laymen, who realize that the public welfare would be vitally damaged in case such bills were passed, must exert themselves to justify animal experimentation before legislative committees.

In recent times the antivivisectionists have concentrated their efforts upon attempts to prohibit experiments on dogs. This activity, recognizing as it does the age-long friendship of dog and man, capitalizes sentiment more effectively than would efforts to prevent experimentation on all animals. Antivivisectionists are frank in declaring their hope that through legislation to prevent experiments upon dogs a beginning may be made in the prohibition of all animal experimentation. Such an attitude ignores the fact that experimental observations upon the dog have been more useful in relieving human suffering than those upon any other animal and further, that dogs in general have benefited profoundly from experiments upon a small number of the group.

There are still many maladies from which people and animals suffer and die, because knowledge is lacking that would enable physicians to cope with them. Voters and legislators must decide whether experiments for the understanding and cure of these diseases—experiments justified not only by common-sense reasoning but by past achievement—are to be hampered or even prevented by sentimental protestations. In modern scientific laboratories, experiments upon dogs and other animals are conducted with far greater consideration than is shown to animals of the street and field, and under a supervision which assures that they are done wisely as well as humanely. Citizens should keep informed upon the meaning, the methods, and the results of medical investigation—a field of endeavor which profoundly affects our welfare, indeed our very existence.

THE DOG'S GIFT TO THE RELIEF OF SUFFERING

When an automobile lacks power, runs irregularly, or makes strange noises, the owner, if he be wise, takes the machine to an expert. The expert knows the uses of each part, the signs of its disorder, and the way to remedy the trouble. He has learned this by observing how the machinery works and how its action becomes disturbed. Conditions are similar for the human machine. Experts in knowledge of the human body have, however, little opportunity to watch its activities

directly. Instead they must study the bodies of lower animals. In examining the workings and the disorders or diseases of the various organs, investigators have employed many lower animals—rats, mice, guinea-pigs, rabbits, cats, dogs, and monkeys. Some antivivisectionists affirm that even when an animal is anesthetized, man has no right to look into its body in order to learn how the parts act. There are others who say they do not object to experimenting on most animals, but they would spare the dog.

Dogs are indispensable for certain types of experiment. They will eat both animal and vegetable food and thus, more than any other available animal, live upon the same diet as man. They are large enough to permit surgical experiments under the structural conditions found in man, and live comfortably in surroundings necessary for most scientific observation.

THE DOG AND OUR KNOWLEDGE OF DISTURBANCES OF THE CIRCULATION, OF BREATHING, AND OF DIGESTION

The marvelous growth of modern medical science began about 300 years ago with Harvey's discovery of the circulation of the blood. Among the animals in which he studied the visible motions of the heart was the dog. Since Harvey's time the dog has served in many investigations of the disorders of heart action, thus furnishing information used daily by physicians in treating heart disease in man. Sir Thomas Lewis, perhaps the foremost living authority on this subject, testifies that the painless sacrifice of a relatively small number of dogs has yielded a "wealth of knowledge which so long as medical science exists will continue to confer great and lasting benefits on mankind."

As men and women pass into the later years of life, they are likely to have an increasingly high blood pressure. It may even become dangerously high. When this condition is found, suitable hygiene must be instituted to prevent catastrophe. The common method now in use of determining blood pressure in man was proved accurate by tests on dogs. Whenever a physician applies the simple cuff to the arm, he and his patient should remember their debt to the dog.

The so-called "prone-pressure" method of resuscitation is used in civilized countries all over the world as a means of giving artificial respiration to revive persons apparently drowned, the victims of electric shock, and the unfortunates overwhelmed by noxious gases. This method was devised by Schäfer, Professor of Physiology

at Edinburgh University. It was first proved efficacious by tests on a few dogs which were successfully revived. Dogs were selected rather than other animals because they alone had chest walls nearly enough like man's in elasticity to serve the purpose. The prone-pressure method of resuscitation has already been the means of saving innumerable human lives and it will continue its beneficent service.

Vital facts about the work of the digestive glands and the course of digestion of different foods in the stomach and intestines have been learned by experiments on dogs. In 1904, Pavlov, the noted Russian physiologist who carried on these studies, was given the Nobel prize in medicine for his many new contributions to our knowledge of the digestive system. Since successful treatment depends greatly upon normal conditions, Pavlov's discoveries are in daily use by physicians.

Fig 1 Each of these boys is seven years old. Both have rickets. Today, through dietary experiments on puppies, we know how such deformity can be prevented

The well-known children's disease, rickets, had long been a mystery and the rational treatment of it awaited explanation. By feeding experiments on puppies the cause of this disease was found to be the lack of essential food factor commonly present in animal fats. The way to prevent or cure the disorder was at once obvious and today sufferers from rickets can be cared for success-

fully. Rickets is one of many diseases affecting both man and animals. Veterinarians and dog breeders make use of the same dietary measures as are employed in our hospitals for children.

THE DOG IN RELATION TO SURGICAL PROGRESS

In no realm has progress been more rapid or more serviceable to mankind than in surgical technic. When a new operation must be tried it may be attended by great risk. Shall the risk be taken by the sick man or woman, or by a lower animal? Small animals are too tiny for surgical operations, therefore the size of the experimental animal is important, and many operations now performed daily on man were first tried on the dog. Harvey Cushing, the renowned brain surgeon, has testified that knowledge of ways to operate on the pituitary gland—a small body at the base of the brain—was derived from a series of surgical experiments on dogs, and that every patient operated on for pituitary disease, and thereby possibly saved from a life of blindness, may thank the dog for this blessing. Furthermore, the amount of kidney substance as well as the amount of the small bowel that can be safely removed—questions made important by accident and disease—was first learned by surgical tests on dogs. The dog helped in discovering methods of uniting the ends of the cut bowel, and of uniting the stomach with the bowel by way of a new opening. By experience with the dog, surgeons have learned to operate on the chest. Operations on the heart, even on the interior of the heart, were first perfected on the dog and later done effectively on human beings. A recent line of surgical progress has been concerned with the relief of the very dreadful pain of that form of heart disease called angina pectoris. Through experiments upon dogs the nerves leading from the heart, and responsible for heart pain, were located and the fact determined that these nerves might be cut without disturbing the action of the heart. Sufferers from angina, who formerly had but transient relief through large doses of drugs, may now be cared for surgically—a result entirely due to experiments upon dogs.

THE DOG AND THE TREATMENT OF DIABETES

Another grave condition afflicting mankind is diabetes, a disease characterized by defective utilization of starchy food. In 1889 experiments showed that dogs developed diabetes if the pancreas was removed. Attempts were at once made to treat the disease by feeding pancreas, but it was not until 1922 that Banting and Best in Canada succeeded in making an extract of dog pancreas which could be given to patients and which controlled the disease. This extract is called insulin. Today insulin is made of beef pancreas. Dr. Elliott P. Joslin, the distinguished American authority on the treatment of diabetes, says of the

discovery of Banting and Best, "Insulin revolutionized the treatment of the diabetic. Before insulin was discovered the average patient literally suffered from hunger and thirst and was without hope because he could not find another diabetic who was living comfortably five years longer than himself. The parents of a diabetic child were panic-stricken and doctors broken-hearted when they learned a child had the disease. One of the most noted children's specialists in the United

FIG. 2. George developed diabetes when five years old. Bob soon became his companion and the picture was taken three years later. George is now a fine young man.

States wished he might never have another diabetic child to treat; so sad was it to see a child starve to death. The average duration of the life of diabetic children was surely less than a year, and that of the largest group of diabetic children in the world under careful observation was less than two years." Today all this is changed. Prior to the discovery of insulin, through experiments on a small number of dogs, no such pictures of diabetic children as those which illustrate this article existed. A short period of miserable invalidism was followed by death. Dr. Joslin writes again, "Thirty years ago when I began treating diabetic children I counted the days they lived. It is hard to believe, but it is true, that now I am beginning to measure their lives in decades of years."

It has been estimated that in the United States alone there are now 1,000,000 people who already have diabetes or will develop it. To this vast horde, knowledge gained by experiments upon the dog gives comfort, hope, and useful lives. If the dog had aided us in no other struggle against disease, we could never repay him for the ammunition he has given us in fighting diabetes.

THE DOG AND THE TREATMENT OF PERNICIOUS ANEMIA

A few years ago pernicious anemia was one of the most distressing diseases with which man was afflicted. It usually affected adults in good health, and, while it required a long time to kill, it invariably did so. Today the patient with pernicious anemia can continue to live usefully and contentedly.

Experiments upon rats and other animals had shown that a diet rich in liver promoted growth in an unusual way. Physicians had thought that

By permission of Lea and Fubiger

FIG. 3. Betty, age two years and eleven months, injecting her own insulin. Many diabetic children do this every day.

in pernicious anemia the patient needed something to promote formation of the blood, but no one had an idea of the nature of the necessary substance. Dr. Whipple and his associates in the University of California undertook the systematic study of the blood under various conditions in dogs rendered anemic by bleeding. In 1922 they found that such dogs, if fed a diet rich in liver, restored the lost blood more quickly than if given any other food. With this knowledge, gained by experiments upon the dog, two practicing physicians in Boston, Dr. Minot and Dr. Murphy, who had long struggled over the terribly distressing task of attempting to prevent patients with pernicious anemia from dying, began to feed such patients with liver. The results were almost miraculous. Pernicious anemia treated with liver was not a fatal disease. The liver supplied something by means of which these unfortunate people could manufacture blood. In the beginning, patients had to eat raw liver. Then various means of concentration were found possible. Today small capsules containing liver extract are furnished the patient. This extract,

when taken daily, controls the disease and allows a wholly normal life.

It is an interesting fact that about one year before the discovery of insulin Dr. Minot, the principal in the discovery of the liver treatment of pernicious anemia, found that he had diabetes. When insulin became available he was treated with this substance. Experiments upon the dog, resulting in the discovery of insulin, in this way saved the man who, later, taking advantage of other experiments upon the dog, developed a method for controlling another formerly fatal disease, pernicious anemia.

THE DOG AND THE TESTING OF DRUGS AND PROTECTIVE APPLIANCES

Still another way in which the dog is helpful to mankind is in the proving of drugs. The strength of some of the most important medicinal

By permission of Lea and Fubiger

FIG 4. Several dogs used in anemia experiments to demonstrate the potency of liver for blood regeneration after blood loss. It was a short step from the experiments on these dogs to the cure of pernicious anemia in man.

agents can be learned only by being tested upon animals. For example, the United States Government requires that the drug epinephrin, also called "adrenalin", must be standardized by injection into dogs. This drug is used universally to check bleeding and to abolish the acute distress of asthma. Cannabis indica, an important sedative, must also be standardized by canine tests. The dangers of many chemical substances in common use have been discovered by experiments on dogs. In this way wood alcohol was first shown to be harmful and capable of causing blindness and death.

Dogs have been of indispensable value in reaching conclusions as to the amounts of dangerous gases, such as carbon monoxide, which can be permitted in the air of tunnels and mines, or in manufacturing processes. They have had an equally important part in the development of protective appliances worn in atmospheres containing poisonous gases, in diving, and in work in compressed air.

THE DOG AND THE TREATMENT OF DISEASE IN THE DOG

Not only have experiments upon the dog alleviated human suffering but they have been profoundly helpful to the dog himself. Two instances will illustrate the striking advances which have been made.

Hookworm in dogs. In 1915 there was no satisfactory treatment for hookworm disease of dogs — a disease widespread over the United States. It was so severe in parts of the South that it was impossible to raise dogs successfully. As a result of experiments on dogs, Dr. Hall of the Bureau of Animal Industry in Washington found that carbon tetrachloride is a satisfactory drug for removing the worms. Ascertaining the value of this drug involved the use of 30 dogs which had been condemned to death in the pound. These dogs were given doses of the drug and painlessly killed after four days. The value of the drug was judged in the only satisfactory way known at present, by collecting the hookworms passed after treatment and ascertaining whether any remained in the dogs' intestines. Since 1921 another and better drug for hookworm, tetrachlorethylene, has been discovered by work on the dog. This has been used with success by the veterinary profession not only upon innumerable dogs but upon cats, foxes and sheep.

It is often a contention of antivivisectionists that dogs are so different from man that nothing of value can be learned through them. The result in the treatment of hookworm is one of the many instances which refute this statement. Carbon tetrachloride and tetrachlorethylene, discovered by experiments upon dogs to benefit dogs, are the drugs used today in treating hookworm in man. The good these drugs have done is evident in the bettered health of millions of human beings who otherwise would be ailing or incapacitated.

Distemper in dogs. Distemper is a highly infectious disease of dogs, attacking chiefly animals from a few weeks to a year old. It is widely disseminated throughout the world, and, in those countries where it has not become established, the introduction of an infected animal at once gives rise to a severe outbreak among exposed dogs. The mortality is invariably high; most authorities consider 50% to be a conservative figure.

It is hardly necessary to describe the picture of a puppy stricken with distemper; for who has not seen one or more aspects of this disease and who does not know the suffering it entails? If the puppy does not die—and, as we have said, 50% do—the disease often leaves its mark in the form of a severe nervous affliction, chorea, or a lingering paralysis. The disease is strictly an animal plague, however; man goes free of it. Why, then, did so many dog owners and dog lovers in the British Isles contribute generously during the

years 1923-1928 to the "Field Distemper Council," which planned to carry on investigations to determine the cause, prevention and treatment of the disease? It was because these persons cherished dogs as friends and wished to save them from preventable illness and death. The subscribers were men, women, and children from all ranks of society. They gave knowing that their donations would be used to carry on animal experiments, to do vivisection, as it is invidiously termed, in the hope of discovering the cause, prevention and cure of distemper. They were willing that dogs should be used in the attempt to save more dogs; and their intelligent perception that the few could be used to rescue the many has been amply justified. As a result of the experimentation, the British scientists developed a vaccine for prevention of distemper and a serum for its effective treatment. The vaccine, the use of which is spreading in this country, prevents distemper in 99% of instances. Indeed it is conservatively estimated that in the United States alone many tens of thousands of puppies are saved each year by means of it.

THE GREAT WAR AGAINST PAIN

The medical profession is continuously engaged in a much greater war than the World War—a struggle against the needless pain, crippling, and premature death not of men alone but of animals too. The recent great victories over disease have been largely won by means of the knowledge gained through experiments upon animals. Man is better justified in enlisting the dog in the struggle against pain and disease than he has been in utilizing his aid in actual warfare, for the dog shares in the victories that are gained.

In the United States all institutions in which animals are used for medical and biological research have adopted regulations providing for the comfort and sanitary surroundings of the animals. All operations must be sanctioned by the laboratory director. He is held responsible for

the importance of the problems studied and the propriety of the methods applied. Furthermore, the regulations require all operations likely to cause greater discomfort than anesthetization itself to be done under anesthesia and to be followed by painless death. Only the director can make exceptions to these provisions, and he can do so only in the cases in which anesthesia, or death of the animal, would defeat the purpose of the experiment.

The advances that have been described indicate that the dog has played an essential rôle in bringing relief from pain and freedom from many sorts of avoidable death. Yet men and animals still suffer and die because their maladies are not understood. The death-rate from cancer is high and this mysterious disease is even more common in dogs than in men. Recent work in England has shown that the means to cure cancer in man can be utilized for animals as well. The skin cancers of dogs yield to treatment with x-ray and radium. In this instance the means of cure was tested first on man because his need was the more pressing; but it has helped the dog too.

The loyalty, devotion, and self-sacrifice of the dog have often been emphasized. The instances that have been given prove that the sacrifices made by dogs have resulted in rich and manifold contributions to human and animal welfare. It is plain that much remains to be learned before both dogs and men shall be free of dreadful scourges which menace their health and existence. Because the dog has rendered to us and to his own kind such immeasurable benefits in the past, we turn to him now with assurance of further benefits. Of the dog used by the medical investigator, William James wrote with appreciative understanding: "If his poor, benighted mind could only be made to catch a glimpse of the human intention, all that is heroic in him would religiously acquiesce." We who know the beneficial results coming from these "intentions" should do homage to the dog through whom they come.

OBJECTIVES OF THE BRONX COUNTY MEDICAL SOCIETY

By WILLIAM KLEIN, M.D., BRONX BOROUGH, NEW YORK CITY

THE inaugural address of the President of the Bronx County Medical Society, delivered on October 19, 1932.

The trinity of objectives of the Bronx County Medical Society must be the following:

Scientific medicine, guarding the public health, and a decent economic status for the physician. Scientific medicine is the easiest of all three. The County Society has already succeeded in arrang-

ing programs that will be helpful to the general practitioner in his daily trials and tribulations.

Guarding the public health is a big problem. The doctor has from time immemorial been the one who did the work, but the credit and, if you please, the cash, went into other channels. It came to pass that the public lost much faith and good will towards the doctor. The reason was simply because the doctor was a secluded person

and organized medicine did not take the trouble to inform the public as to who did the real work. This tendency assumed rather alarming proportions in our own midst. It is high time that we come to the public and inform them of the real truth. We cannot remain cloistered any longer. To this end our Society shall endeavor to accomplish something concrete for the benefit of the public as well as for our own members.

Public health problems have assumed the aspect of a peculiar state of affairs. For the past decade or more, the tendency of City, State and National authorities has been to assume more and more the responsibility of the work that was previously done by the general practitioner. The pendulum along this line has swung too much toward paternalism. The encroachment became almost confiscatory. While the doctor was really the man who accomplished much in this field, public health became a political football which was thrown into the eyes of the public at certain periods of the year. No one foresaw the consequences that would follow the cessation of this work in times of economic depression. At present the philanthropic organizations must abandon this work. Even the City and State have come to a realization that they cannot continue along these lines. The result is a state of affairs that may have serious consequences. Our Society is ready to resume this work, and, in cooperation with certain authorities, hopes to gather the loose ends and stand by the public needs. The indigent poor

must not point a finger at our profession for not doing all we can for them. Along these lines certain definitely outlined plans are already in operation. Others are shaping themselves and with a little effort will be taken up and, I am sure, work out for the benefit of all concerned. Above all, our Society will jealously guard the contact between the family physician and the patient.

The economic distress of our profession, I believe, is worthy of serious thought. In times of hardships many plans and suggestions are forthcoming. Each is sure to bring about the millennium. It would not be wise to be rash and decide upon one course or another without due deliberation and foresight. The immediate and necessary thing to do now is to take our opportunity and cause the family that was weaned away from the family doctor by too much paternalism to revert back to him. The patient will be cared for and the tendency to pauperization must be kept at a low tide.

All this and many other future activities cannot be accomplished by your officers without your hearty cooperation. The cynical indifference and at times the unjust criticism of members are never helpful and often a hindrance. Members must understand that the Comitia Minora is doing more than the average member realizes. The open meetings are the outcome of the hard work that is done behind the scenes. I bespeak your indulgence and cooperation with Society work during the coming year.

THERAPEUTIC MASSAGE

By KRISTIAN G. HANSSON, M.D., NEW YORK, N. Y.

Read as part of a course on Physical Therapy in Traumatic Conditions, arranged by the Committee on Public Health and Medical Education of the Medical Society of the State of New York, for New York and Bronx County Medical Societies.

THE purpose of this paper is to present the fundamental principles of massage to the medical practitioner. It is not intended as instruction in this much-neglected branch of physical therapy; for such instruction I refer to Mennell's excellent text book on massage.

Massage belongs to the so-called natural therapeutics. We might trace massage back to the animals licking their injuries with their tongues. The inventive human mind substituted heat for the animal breath, our hands for the tongue, and a lubricant for the saliva. The practical application ranged from the stimulative treatment of the healthy to the laying on of hands of the dying.

It was with Harvey's explanation of the circulation that the scientific basis of massage was first explained. The next development we see in the establishment of schools for massage. The best known of these schools were in Sweden, where they were under medical control.

Much of the action of massage is directly or indirectly on the circulation. When the physiology of the capillaries is better understood, we will probably find further scientific use of massage. For practical purposes we will divide the action of massage into mechanical action and reflex action. Mechanical action is the more important of the two and may be exerted in four ways.

1. By assisting the circulation of blood through the affected part.
2. By aiding the flow of lymph.
3. By tension on structures that can be freed or stretched.
4. By pressure on the abdominal viscera.

By assisting the venous return we can lessen the blood column in front of the arterioles; thus allowing the blood to pass through the capillaries more readily. It is rather important to place the

part under treatment in such a position that one works with gravity instead of against it.

Effect on the Lymphatics.—Stagnation of the lymph is a common occurrence. The pressure in the lymphatics is even less than in the veins and therefore even less force is used in the treatment of edema or lymphatic deficiency. It is important to treat the proximal part first for the same reason that we open the nozzle of a hose before we can get any water out of it. Muscular relaxation is important. Elevation of an extremity alone can reduce an edema but in order to restore the vasomotor tone, massage must be added.

Effect on Repair Tissue.—Injury and disease are healed by the production of connective tissues. When this repair tissue is laid down in the soft parts, contractures often occur. When laid down in a joint, stiffness or ankylosis may follow. Massage will help to prevent or overcome soft tissue contraction and stiffness in a joint. The treatment of such pathologies requires forceful and penetrating manipulation.

Reflex Action of Massage.—We are familiar with the muscular spasm accompanying low back pain, fractures, and other painful pathological conditions. These are reflex contractions for protection. We may therefore say that peripheral irritation may produce reflex contraction. It seems only reasonable to believe, with Mennell, that if an irritating form of peripheral stimulation can produce muscular contraction, a sedative application can produce relaxation.

Our instinctive rubbing of the eyes and temporal regions gives relief from fatigue. The results obtained with massage in generalized fatigue of the nervous system and in insomnia must be explained by a reflex action. Lucas-Champoniere's often quoted treatment of fresh fractures is another example of how one can relax the muscular spasm by means of massage and thus easily reduce the fracture.

Hand Movements of Massage.—Stroking or effleurage is any sliding of the hand over the patient's body. We divide the stroking into superficial and deep.

The superficial stroking is the chief movement to secure reflex action and also the mechanical action on the superficial circulation. The stroking must be unidirectional, slow, gentle, and rhythmical. The direction is the same as that of the flow in the veins and lymphatics. The average stroke should take about five seconds and should be continuous and even. It is better not to touch the patient's body on the return stroke. Each hand movement should be identical: it must be firm enough so that the patient is conscious of the hand throughout the entire stroke. Rhythm is necessary to make stimulus even and to prevent jarring at the beginning and at the end of the

stroke. The time of the return stroke should be the same as the active stroke. Complete relaxation of the operator's hand is essential. Needless hurry and scratching with the fingertips at the beginning or termination of the stroke are the commonest mistakes made.

Deep Stroking or Effleurage.—This requires complete relaxation of the patient. The action is mechanical on the return flow of blood and lymph and also increases the tone of the vasomotor system. It differs from the superficial stroking in the force applied. This should be strong enough to empty the veins but not deep enough to act on the circulation in the arteries.

Compression Movements, also called Petrissage, Friction or Kneading.—These include any localized kneading of the soft tissues. The whole hand or part of it is used in apposition to the other hand. Small or large circular movements are performed with the hands as a whole, the hyperthenar eminence or fingers which work clockwise. The direction of the stroke is toward the heart but the proximal part should be treated first.

Complete relaxation of the patient is necessary. Even and steady pressure is essential and the largest surface of the hand is always preferred to a small surface; *i.e.*, a fingertip exerting strong pressure will produce a protective reflex with muscular contraction—a grave error in technique. The main effect of this movement is on the soft tissues, especially the muscles. While exercises will result in an acid reaction of blood serum due to the accumulation of waste products, heat will produce an alkaline reaction. Massage, however, will restore the normal balance of a muscle, eliminate waste products and increase fresh blood with nutrition and repair material. It will bring a sense of comfort and well-being to the muscles and thus render them more ready for new functional activity. Massage will restore a muscle after exertion much quicker and more completely than rest will.

Percussion Movements or Tapotement.—These are a series of short, rhythmical blows delivered in rapid succession. By means of applying the hands and fingers in different ways, we speak of hacking, clapping, tapping and beating.

Hacking is the most common form. Hands must be relaxed with fingers separated. Both hands are used alternately. As the blow falls, the fingers strike together. The hacking should strike the muscle transversely and will produce a mechanical compression. We can use all fingers separated or only the little finger separated from the rest or all fingers closed striking the patient's body with ulnar surface of the little finger.

Clapping is performed by cupping the hands and letting them strike the body sharply when they produce a deep, clapping sound.

Tapping is done by the finger tips and is the most delicate percussion while beating is the most vigorous form. The fist is half-closed and the palmar surface is used for beating the heavy muscles of the body. The predominant action of these percussion movements is that of stimulation, by which we mean an increase of the normal activities of the muscle. Vibration is a form of percussion. The action in this is also stimulative. The hand vibration is strenuous to perform; hence mechanical vibration is probably superior.

Rules for Patient.—When massage is given for stimulation, the first half of the day is preferable. When it is intended for repair, the latter half of the day should be preferred. No general massage should be given within one hour, at least, after a meal. The skin of the patient should be clean and the patient should be undressed—at least no constricting clothing should be worn. It is wise to make it a rule that a patient must be in the recumbent position, well supported from head to foot—for only in this position can the patient relax completely. This should also be observed when local treatments are given.

Rules for Technician.—In no other form of treatment does the patient and the technician come in closer contact than in massage. The cleanliness and neatness of the operator is therefore a necessity. Another prerequisite for a massage technician is dry and warm hands. Intelligence is, however, much more important than strength in the hands. The technician must place herself in such a position in relation to the patient that there is a minimum strain on her own body.

Lubrication.—There is little or no absorption through the skin and the various preparations in use for massage can therefore be considered as lubricants, to overcome the resistance of the skin. We have two main lubricants, the powder and the fatty acid base production. The powders should be used when the patient has a hairy skin, when there is a tendency to eruptions or when the skin is moist. The fatty acid productions should be used on a dry skin. A lubricant is not always necessary but such application requires more skill. When a lubricant has been used it should be removed by a solvent, such as alcohol.

Prescription of Massage.—Massage should be preceded by some form of heat. For local treatment, moist heat—a towel wrung out with hot water is efficient and convenient. For general

treatment, heat from incandescent lamps is more practical. Massage should be followed by exercises and for this reason a massage technician should be trained also in therapeutic exercises.

Application of Therapeutic Massage in Industrial Cases.—When the employer and the state took over the responsibility for injuries suffered by the employee in his work, we all thought that the medical relation between modern industry and modern man had been solved. This is far from true because the physical therapy clinics that were fostered by the insurance carriers were very inadequate—to say the least. It is true that modern electro-therapy was introduced in these clinics but I believe that the results obtained were worse than if only massage, heat and exercises had been given. So many patients are treated by one operator that it is impossible to do justice to anyone. When this short treatment is divided into heat, electrical treatment, massage and exercises, the patient does not get enough of anything. The physical therapy treatment becomes a farce.

At the present time when there are indications that the general practitioner may become a part in the compensation work, my plea is for honest and rational treatment of the patients. When electrical treatments are indicated, they should be used with discrimination. The general practitioner should become familiar with the advantages and limitations of massage. When injuries are sustained to the soft tissues, rest is the immediate treatment; in order to restore normal circulation massage is added and to regain normal function exercises are necessary.

If the physiological action of massage is understood, the indications are evident. The contra-indications are pathological conditions that might be spread by manipulation. Such pathologies are neoplasms, myositis ossificans and acute infections. Febrile diseases are also contra-indications for therapeutic massage, nor should patients with skin diseases be given massage. Precautions must be used in advanced arteriosclerosis, and edema, and massage is especially dangerous in phlebitis.

A well-balanced mind must be used when we employ physical therapeutic measures. When this is done, massage should be used extensively in industrial therapeutics. It must, however, be applied with intelligence rather than force and this can only be done by well-trained technicians, directed by physicians, who are able to prescribe massage with discriminating understanding.

POLIOMYELITIS

A Plan for a Study and After-Care of the 1931¹ Brooklyn Epidemic

By MURRAY B. GORDON, M.D., BROOKLYN, N. Y.

From the Sub-Committee on Poliomyelitis, Medical Society of the County of Kings.

Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

THIS is a preliminary report of a study undertaken by the Medical Society of the County of Kings of the recent epidemic in Brooklyn. The Committee on Poliomyelitis is a sub-committee of the Committee on Public Health and is composed of 3 pediatricists, 3 orthopedists, 2 physio-therapists (who are physicians), 2 neurologists, 2 public health experts, 1 pathologist and 1 hematologist.

The purpose of the study is the clinical investigation of the acute and chronic stages of the disease, the effects of various methods of treatment, the efficiency of after-care and the ultimate fate of the children.

It was decided to limit the scope to the 1931 epidemic in the Borough of Brooklyn of the City of New York, which comprises the County of Kings of the State. Its population in 1930, according to the census, was 2,560,401. There were 2,166 cases of acute poliomyelitis reported in this borough during the epidemic which lasted from about the first of July to the end of September, 1931. Scattered cases during the next three months brought the grand total from July 1st to December 31st to 2,325 cases. The death rate was about ten per cent.

In the 1916 epidemic, which lasted for about the same length of time, Brooklyn, with a population of 1,928,432 had 4,312 cases with 1,147 deaths, a mortality incidence of 26.6 per cent.

Under 1 year of age	86
One year of age	206
Two years of age	338
Three years of age	296
Four years of age	234
Five years of age	156
Six to twenty years of age.....	677
Above twenty-one years of age....	27
Age not given	146
Total of 1,316 under school age.	
Total of 1,993 under 21 years of age.	

Table 1. Age Distribution of Cases in 1931

The distribution of the cases was about the same in both epidemics and showed a tendency to be grouped more or less in proportion to the varying density of the population. There was a greater relative increase in two sections in the recent epidemic, those of Coney Island and Gerritsen Beach, probably due to an increase in the population within the last ten years. The two pin dot maps illustrate the distribution in 1916 and 1931, each dot designating a case. The colored population was apparently less susceptible

to the disease in spite of its being "sandwiched" in between the affected areas.

The age distribution in the 2,166 cases in the recent epidemic is shown in table 1.

The following procedure of investigation has been planned for the next five years:

STUDY OF EPIDEMIC OF 1931

A. Acute Stage

1. Epidemiology, number of cases, distribution, etc., as compared with that of 1916.

2. Study of all clinical records of hospitals and private physicians by means of a special form.

3. Special emphasis on the preparalytic stage—its clinical course, the evaluation of spinal fluid findings in the diagnosis and the effects of various methods of treatment employed in this epidemic; convalescent serum, transfusion from immune donor, immune horse serum and simple lumbar puncture without any other specific treatment.

4. Comparison of the subsequent course of cases diagnosed in the preparalytic stage as compared with those not seen until the paralytic stage.

5. Respirator cases studied from the viewpoint of the clinical picture, the number which died in the acute and post acute stages. The cause of death in those children who died after discharge from the hospital to be investigated to determine any possible relationship to the paralysis. Present condition of those who are still living.

6. General treatment.

B. Chronic Stage

1. Follow up of patients in hospitals and out patient department and through communication with private physicians for those receiving home treatment.

2. Comparative studies of condition on discharge and that found on periodic examination at stated intervals.

3. Non-paralyzed and recovered cases to be observed and followed up for one year after discharge.

4. Paralyzed cases to be under study for the entire period of this investigation.

5. All deaths subsequent to the acute stage to be investigated to determine any possible relationship to previous or existing paralyses. Causes of death to be reported by Department of Health (Bureau of Vital Statistics).

6. Comparison of death rate in these children and that of general population of the same age and period.

7. Final evaluation at the end of five years as

to the effect of various forms of orthopedic and other therapeutic treatment.

The following plan is to be employed in the after care and preparation for future epidemics:

Community Plan

A central bureau is to be established with representation from the following:

1. Medical profession as represented by Committee on Poliomyelitis of County Society. It is to study the disease as outlined elsewhere in this report and is to keep abreast of all new information on the subject.

2. Nursing as represented by the Visiting Nurses' Association of Brooklyn. This is an organization with a staff of 135 registered graduate nurses who are giving nursing care to the sick in their homes and health supervision to individuals or families requiring their services within the Borough of Brooklyn. The cost per visit is \$1.10 and patients are expected to pay in whole or in part or nothing at all, depending upon their economic conditions. The borough is divided into seven zones, each under the jurisdiction of a supervisor.

The Medical Society of the County of Kings has since 1924 acted through its Committee on Public Health as the Medical Advisory Board of the Visiting Nurses' Association. At that time, standing orders covering the bedside work of the visiting nurses were prepared by a joint committee of the nursing group and the county society. In 1929 the Society prepared similar standing orders for public health educational work.

As a result of this close contact the possibility for cooperative work in any public health procedure is always present. In our plan for the present study, we are receiving valuable statistical case report and other assistance from this association and expect to receive even greater help in follow-up work as outlined elsewhere in this report.

The nurses of the Visiting Nurses' Association have cared for 2,362 poliomyelitis cases in 1931 which included practically all those in Brooklyn and in the adjacent county of Queens. The organization has supplied to the Committee information as to the present condition on almost all of the Brooklyn cases.

3. The City Administration as represented by the Departments of Health and Hospitals. It is to provide all possible facilities in fighting the disease, have police powers during an epidemic and provide adequate beds for all requiring hospitalization. During the recent epidemic, about 1,300 cases were admitted to city hospitals in this borough. The City should also provide transportation facilities for all poliomyelitis victims.

A need exists in the Borough of Brooklyn for

the transportation of crippled children to and from their homes and the various clinics. We are indebted to the Transportation Committee of the Public Health Committee of the Brooklyn Chamber of Commerce for the following information. The Board of Health does not in any way enter into the field of transportation, so that when an epidemic is over the question becomes an individual problem. All of the hospitals in the borough that have orthopedic clinics and physiotherapy departments report that transportation is necessary and are now collecting data on this matter.

The Committee for the crippled of the Brooklyn Bureau of Charities is supporting one bus with chauffeur and attendant six days a week to three hospitals. Transportation to another clinic is provided for by a private individual through the Visiting Nurses' Association. The latter states that 120 children are receiving treatment at their respective homes by their nurses two to three times a week who could be treated at clinics if adequate transportation facilities were available. All in all there are about 80 children, mostly in the pre-school age, who are being transported.

Some of the transportation will be withdrawn soon because of lack of funds and the likelihood of obtaining additional funds from private sources seems remote. It is estimated that a bus operating for approximately 19 children making three trips a week and being in use from early in the morning until late in the afternoon costs approximately \$40.00 per week. On the basis of 100 children requiring transportation the expense involved for the city would be less than \$1,000 per month and at time goes on there will be a decrease in the frequency of visits.

4. Private hospital as represented by the Hospital Council of Brooklyn. Private hospitals should be permitted to take care of acute cases if they can provide proper isolation for those whose parents wish to pay for their care. Free cases should be sent to city institutions. The city should reimburse for free cases in private institutions only in the event that the particular hospital has a special accepted method of treatment which cannot be obtained in a city institution or in the event of lack of beds in city hospitals. About 500 cases were treated in private hospitals during the recent epidemic on both a free and paying basis. There are about 253 paralyzed children who are being treated at present in both city and private orthopedic hospitals.

5. Social welfare organizations such as the Brooklyn Bureau of Charities, Association for Improving the Condition of the Poor and Children's Welfare Federation should be represented.

6. The public as represented by the Chamber of Commerce, Rotary Club and other lay organizations. They should assist in providing transportation and in the raising of money for the

financing of this plan, social welfare purposes, establishment of convalescent homes, etc.

7. The Board of Education should provide proper schooling for those unable to go to school. Older children should be trained for vocational occupation adaptable to their deformities.

For over a quarter of a century there has been organized in the public schools of New York City a system of special education for physically handicapped children. Today this special school and health care includes special classes in public school buildings, hospitals and convalescent homes and also home instruction for home-bound children of normal mentality.

A thorough preliminary education is provided, giving the same training as that imparted to children in regular classes leading to graduation and High School privileges. The direct supervision and administration of the crippled and other physically handicapped children are in charge of an assistant director of health education in the Board of Education who is a physician.

The children attend graded classes in special class-room located upon the ground floor. The rooms are especially equipped with furniture which is adjustable for all types of physical defects. Classes are also conducted in practically all hospitals and convalescent homes, instruction being given to those children who are certified by their physicians as being physically fit to receive it.

Home instruction is provided for those children who are discharged from hospitals to their homes but are too helpless to attend the special classes in schools. The home teaching is given in both elementary and high school work.

The Board of Education furnishes transportation for crippled children to and from home and school but not to clinics.

The Central bureau is to have the following functions and authority:

1. To define and allocate the function of each constituent agency.
2. To co-ordinate and supervise the activities of each.
3. To list all possible donors of convalescent serum so as to assure contact at all times. This is to include all former poliomyelitis patients irrespective of the date of illness. Change of address is to be obtained through field workers of Visiting Nurses' Association or voluntary notification by patient.
4. All prospective donors to be also listed as to type of blood grouping, year of illness, name of hospital in which treatment was obtained or if treated at home, name and address of attending physician at the time. Every case must be authenticated. Every individual who is to be a blood donor must meet all the requirements of professional donors as to Wassermann reaction, general health, etc.

Procedure in Time of an Epidemic

1. On the first appearance of an epidemic, a meeting of all the constituent agencies is to be called and plans formulated for combatting it. Subsequent meetings to be held at least once a week or oftener.
2. The borough is to be divided into definite zones corresponding to those of the Visiting Nurses' Association (at present the latter organization has 7 districts).
3. The central bureau is to control the collection and distribution of all convalescent serum and the allocation of blood donors for transfusion.
4. A supervisor is to be assigned to each district who must be a physician who is capable of performing lumbar puncture and typing of blood. He is to be responsible for the activities of his district.

FIGURE 1.

Plan of organization of Community plan for the study and after-care of Poliomyelitis.

5. Contact is to be made immediately with each individual on the list of the Bureau.
6. Patients in the preparalytic and acute stages are to be typed for blood grouping at the same time that a lumbar puncture is done.
7. A list of all new patients is to be forwarded daily by each hospital to the Central Bureau in duplicate, the bureau retaining one and the Visiting Nurses' Association the other. A similar list of those treated at home is to be supplied by the Health authorities.

Record forms, nomenclature and designation of degree of paralysis should be standardized.

The following procedure is that employed by the Visiting Nurses' Association in the recent epidemic and may serve as an example:

"All the nurses on the orthopedic staff of the Visiting Nurses' Association of Brooklyn have special preparation for this field of nursing.

"When a new case of poliomyelitis is reported to the Visiting Nurses' Association by the Board

of Health, hospitals, Children's Welfare Federation, or other sources, the call is sent to the nurse in that district. She makes a visit in the home as soon as possible. The patient may be in the home under quarantine or may be in the hospital. In either case the nurse instructs the family to call the Visiting Nurses' Association when the child is released from quarantine or returns home. Families usually do this. During the 1931 epidemic Kingston Avenue Hospital sent daily reports to the Visiting Nurses' Association which stated all patients discharged to the family or an institution, change of diagnosis, no case and deaths. This was an enormous aid in reducing the time between the first and second visit of the nurse to the family.

"When the patient is released from quarantine the nurse plans with the mother for medical care:

"1. If the family has a private physician the patient is referred to him for examination and after-care.

"2. If during the acute illness no physician was in attendance or there is no family physician and the family is unable to pay for such service the nurse suggests that the patient attend the nearest orthopedic clinic. She makes subsequent visits to see that this suggestion has been followed.

"If the clinic physician advises massage and muscle re-education and for some worth-while reason the family is unable to take the patient to the clinic for this treatment a Visiting Nurse gives the treatment in the home. The child returns to clinic for examination. The treatments are given in the home when the patient is under the care of a private physician and when the family is unable to afford a private masseuse.

"All patients are visited at regular intervals over as long as is necessary or until discharged by the physician."

PRELIMINARY FINDINGS

Since its organization in September, 1931, the Committee has been in close contact with all of the agencies listed in the plan and has acted as the Central Bureau during this time. It has practically all of the records of the hospitalized cases. Through the Visiting Nurses' Association, the orthopedic clinics, special orthopedic hospitals and private records of orthopedists, it has knowledge of the present condition of the majority of the children. It has a record of every child who is obtaining transportation and home schooling. It has a record of all the children who have died with the cause of death.

Types of Treatment	Convalescent Serum	Transfusion from Immune Donor	Immune Horse Serum	Lumbar Puncture*	Total
Number of Cases	67	25	12	180	284
Number Paralyzed	26 (39%)	4 (16%)	6 (50%)	47 (26%)	83 (29%)
Number Not Paralyzed	41 (61%)	21 (84%)	6 (50%)	133 (74%)	201 (71%)
Number Died	1	1	0	6	8 (3%)

* Designates no other treatment in addition to this.

Table 2. Results of Treatment

"3. If a physician sent the child to the hospital and the family can no longer afford his continuance service, the association sends him a form letter, endorsed by the Kings County Medical Society, advising him of the financial condition of the family, and asking him if he wishes to attend the patient or have him referred to a clinic.

"These suggestions are made even though there may be no evidence of paralysis.

"While waiting for definite orders from the physician the nurse instructs the mother in the general hygienic care of the patient and demonstrates the means of preventing deformities of the affected parts.

It has been impossible, however, to correlate these facts as yet. It was not our intention to include any clinical studies in this preliminary report, but we will briefly refer to two procedures which were used on a large scale in this epidemic, the treatment of the preparalytic stage and the use of the Drinker respirator.

Of 1,304 hospital cases which were analyzed, 284 were admitted in the preparalytic stage. The effects of the various methods of treatment are indicated in table 2.

The administration of convalescent serum (intramuscularly, intravenously and intraspinal) was not followed by as good results as with lumbar puncture alone. Transfusion from an im-

mune donor was more effective but on the whole, only 10 percent better than with no specific treatment. On the basis of the findings, we feel that the last word has not been said on this type of treatment.

This is too small a series to permit any definite conclusions but some generalizations may be permitted of the entire group. Irrespective of type of treatment, 71 percent did not develop any paralysis and only about 3 percent died. This tends to show either that there were milder cases or that recognition in the preparalytic stage, and lumbar puncture with or without any additional treatment tend to cut down on the severity of the subsequent clinical course.

We have record of 65 cases in which the Drinker respirator was used in paralysis of the intercostal muscles. This number does not include any cases of the bulbar type. The results obtained in "respirator cases" are as follows:

Died in acute stage.....	42
Died subsequently (days, weeks or months after removal from respirator).....	7
Still living	16

All of the children who died subsequently succumbed to pneumonia. Of those who are still living, practically all have almost complete paralysis. The longest period in which it was necessary to continue respirator treatment was 9 months. This was in a boy who is still in the Kingston Avenue Hospital and requires the respirator every night.

The Committee wishes to acknowledge its indebtedness to the agencies and hospitals of Brooklyn who by their hearty co-operation have demonstrated that this plan is feasible and practical. We especially wish to thank Dr. Alec N. Thomson, Director of Medical Activities of the Medical Society of the County of Kings. Dr. Alfred E. Shipley, Chairman of the Public Health Committee, Miss Elizabeth Stringer and Miss Marion Ballantyne of the Visiting Nurse Association and Miss Sadie Engel, formerly of the Russell Sage Foundation.

SUMMARY

This is a preliminary report of the Committee on Poliomyelitis of the Medical Society of the County of Kings which is undertaking a study of the recent epidemic in Brooklyn. The Committee consists of 3 pediatricists, 3 orthopedists, 2 neurologists, 2 medical physiotherapists, 2 public health experts, 1 pathologist and 1 hematologist.

A five-year plan is advanced for community study, after-care and control under a Central Bureau consisting of seven organizations: 1. Poliomyelitis Committee of the County Medical Society. 2. Visiting Nurse Association. 3. The City Administration through the Departments of

Health and Hospitals. 4. Private hospitals. 5. Chamber of Commerce and similar lay organizations. 6. Social service and Welfare agencies. 7. Board of Education.

The procedure is divided into the following phases:

1. Study of the epidemic of 1931 in Brooklyn. This will be investigated from both the clinical and epidemiological viewpoints. All clinical records of hospitals and private physicians are to be studied on special forms, paying special attention to the preparalytic stage, the effects of various methods of treatment employed and the subsequent course of cases diagnosed in this stage as compared with those coming under treatment later.

2. All patients are to be followed up for five years or until the time of death. All courses of death subsequent to the acute stage are to be studied to determine any possible relationship to previous or existing paralyses. Respirator cases are to be especially investigated from this viewpoint. Final evaluations of all treatment and methods are to be made at the end of the study.

3. Plans for after-care call for coordination of all the agencies in the Central Bureau with the Committee of the County Society in a prominent role. Periodic examinations, transportation and schooling and means for convalescent care are to be provided.

4. The Central Bureau is to have available at all times a list of all patients for the purpose of obtaining convalescent blood or immune whole blood for transfusion. It is to be responsible for their collection and distribution in times of epidemics. The functions of the Bureau are described.

5. The preparation against epidemics from a community viewpoint calls for cooperative action of all the organizations in the plan. The procedures are described including the subdivision of the city into zones.

6. In times of epidemics, hospitals are to form "poliomyelitis teams" consisting of a pediatricist, an orthopedist, a neurologist, a hematologist and a pathologist.

An evaluation of the various methods of treatment employed in 284 cases in the preparalytic stage shows the following percentage of subsequent non-paralysis:

Convalescent serum, 61; transfusion from immune donor, 84; immune horse serum, 50; lumbar puncture without additional treatment, 74. These figures tend to show that the other methods of treatment are apparently of no better benefit than simple lumbar puncture.

Of 65 cases in which the Drinker respirator was used in intercostal paralysis, 42 died in the acute stage, 7 died within the next few months and 16 were still living at the time of report.

A CLAMP TOURNIQUET

By HARRY COHEN, M.D., F.A.C.S., NEW YORK, N. Y.

Presented before the Surgical Section of the New York Academy of Medicine, Friday, May 6th, 1932.

THERE are many tourniquets now on the market. This is readily conceivable considering the enormous amount of blood and vein work being performed daily. However, it is surprising that with this large number of tourniquets now in use no particular one has met with universal approval and the one most used is still the ordinary piece of rubber tubing tightly wound around the arm and held in place with an artery clamp. This new instrument is therefore presented and is termed "A Clamp Tourniquet." I believe that because of the advantages which it possesses this clamp-tourniquet will replace all the contrivances now in use.

As its name implies it is essentially a clamp and works on the same principle as any other clamp as for example an artery-clamp, sponge-forceps, etc. The tourniquet end or distal part of the clamp is made of flexible steel and curved to fit the average arm. There is a larger model to fit an average thigh and leg for varicose-vein work.

The clamp is made of steel, of rugged construction yet very light in weight, firm, strong, dependable, practical and as near fool-proof as possible. It is a surgical instrument in every sense of the word and can be sterilized where sterilization is necessary as when used in blood transfusions. It is positive in action. It takes but a few seconds to apply and its release is instantaneous. After the clamp is applied the pressure can be regulated by means of a fine adjustment screw. In this manner the pulse can be made to disappear or become palpable again by a few turns of this adjustment screw. It is of especial value and ideal for office use for the introduction of any solution intravenously and where assistants are limited or even absent. The clamp is applied and the vein for injection made prominent; the needle is then inserted into the vein and then by means of the fine adjustment screw the doctor or even the patient himself can release the obstruction

to the vein without disturbing the needle. The solution is then injected into the vein without the aid of any assistants.

Professional donors have remarked that the clamp-tourniquet exerts a more even pressure on the arm, does not tire or pain the arm, does not

FIG. 1.
A Clamp Tourniquet

pinch the arm, does not slip and can be tolerated a longer time without discomfort. They usually inquire why others do not use the clamp. The clamp has been employed by the technician of our hospital for the past few months for the taking blood for blood-chemistry, blood-sugars and Wassermanns. In this department it has been found almost indispensable. The clamp has also been used on the forearm to control a hemorrhage in a traumatic laceration of the radial artery. In this case the demonstration of the clamp was prompt and spectacular.

RUBELLA*

By JOHN RANDOLPH GRAHAM, M.D., NEW YORK, N. Y.

RUBELLA is generally conceded to be the mildest of the Acute Exanthematous diseases, and inasmuch as it is devoid of serious possibilities to the patient infected, the medical profession at large treat it more or less as a joke. Why, then, it may be asked, waste time in considering so unimportant a subject? Well, the explanation or excuse is that after a good many years of intimate contact with all its phases, the writer finds it about the most interesting of all the eruptive diseases; and, furthermore, he is of the opinion that from a viewpoint of diagnosis, it offers as many puzzling problems as all the other exanthemata combined. With this thought in mind, I would like to go into the details of this affection rather minutely, if I may, though I shall try to be as brief as possible.

The correctness of the assertion made above as to the diagnostic troubles afforded by Rubella, can be verified to the satisfaction of any one sufficiently interested to glance through the literature bearing on this disease; for it will be found there that since it was first accurately described about the middle of the 18th century, it has on frequent occasions figured as the storm center of heated controversy and discussion. That it has been studied with great interest, the long list of synonyms noted in the average textbook also bears witness.

Rubella can with truth be described as the creature of many moods. It can be, unmistakably, *itself*, but it also has the peculiar faculty of resembling real measles in one instance, scarlet fever in another, and then it may simulate both measles and scarlet fever in successive stages of the same attack. For those of us to whose lot it has fallen to see much of this interesting disease, the varying ways in which it presents itself to the eye of the observer, make it a very fascinating subject for study, and it has always been particularly hard for the writer to understand how such a profuse and intense cutaneous disturbance as is so frequently seen in rubella, can at the same time be so ephemeral. A characteristic feature of this malady, however, is that the most marked of the rashes often disappear over night.

Rubella was made a reportable disease by the Board of Health of New York City in 1904. The number of cases varies greatly year by year, the largest number recorded being in 1917, when 8,556 reports were registered, a total of 2,000 more than the scarlet fever reports for the same year. Naturally, because of its extreme mildness, a great many cases never get in the records. A few years ago the Division Chief in one of the boroughs of the city noticed that an unusual num-

ber of rubella cases was being reported, and that at the same time there was a notable drop in the scarlet fever figures. Recalling the fact that there was a strong tendency to error in differentiating between these two diseases, he inaugurated a follow up campaign, but found nothing to indicate that an abnormal number of mistakes in diagnosis were being made. With rubella fairly prevalent each spring, and with the notable decrease in recent years of the incidence of scarlet fever cases, accompanied also by a marked lessening of the severity of the symptoms in this disease, there has been added a new and interesting feature to the matter of eruptive disease diagnosis. It may be stated, in this connection, that a good part of the work of the Department of Health diagnosticians is along the line of rectifying errors of diagnosis, resulting from the similarity of the symptoms found in rubella and scarlet fever.

Unquestionably, instances in which measles is confounded with rubella are frequent enough, but the short period of isolation and the absence of rigid supervision by the department in the former disease, result in comparatively few requests for revision of diagnosis. A striking fact in base hospital service, as experienced by the writer, was that although there was considerable rubella, characterized, let me say, by eruptions that were wonderful to behold, there was almost a total lack of recognition of the true nature of the affection by the majority of the medical officers.

The opinion that rubella is a mild form of scarlet fever or a modified measles is met with from time to time. The fallacy of such an idea is readily proven by the fact that this disease reproduces itself exactly after a different period of incubation than that which precedes scarlet fever or measles.

Rubella is probably spread by the secretions, and, perhaps, by the exhalations from the nose and throat. It is not as contagious as measles, but more so than scarlet fever. The exciting organism has never been isolated. It occurs in this locality, only in the period from January to June inclusive, and I would personally view with suspicion a diagnosis made at other times in the year. To be more exact, our annual visitation usually starts about March 15th, the outbreak occurring very suddenly; it gains in force for about two weeks, holds its own for six weeks or two months, and then subsides as suddenly as it began. It is more prevalent in school children, between six and fifteen years of age, than at any other period of life. It is exceedingly rare under one year, and adults appear to be quite immune except when gathered in camps, institutions and

* Read before the West End Medical Society, March 26, 1932.

other places where grownups are closely associated with each other.

Symptomatology: The incubation period appears to be the longest found in any of the eruptive diseases—between two and three weeks. Often there are no prodromes, the child frequently going to bed perfectly well, and awakening in the morning with the face peppered with the rash. Generally, though, the patient will complain of a little headache, malaise, drowsiness, and perhaps may sneeze a few times before the rash appears. This rash is first noted behind the ears, on the scalp and on the face, being particularly prominent around the mouth, a point, you will observe, of great value, when it comes to considering its differentiation from scarlet fever. It spreads with great rapidity and involves in quick succession the neck, trunk and extremities, the whole movement rarely taking over 24 hours to complete its development. The eruption fades with about the same rapidity that characterizes its appearance, and it is not uncommon to find a brilliant rash on the legs, with the face and neck entirely clear, and the intervening areas clearing. The initial character of the rash is macular as a rule; it is also spoken of as slightly papular. This latter characteristic is difficult of detection, however, while the macules are discrete, but when the rash becomes confluent, the elevation becomes quite distinct. The macules range in size from that of a pinhead to that of a split pea, the lesions of the latter size commonly predominating. The edge of the macule when fresh is clean cut, the larger lesions having an oval shape and in the early life of the rash, the macules appear to be set on the skin, which seems very white by contrast. It should also be stated that there is another type of eruption in this disease, not merely so frequently observed as the macular form, just described, but it occurs often enough to cause much trouble. I refer to the scarlatiniform type of rubella. In this type, the scarlet like eruption very early and quickly spreads from pinhead sized macules as nuclei. You can generally detect these small macules outlined in the fresh rash, giving it a punctate appearance. This form I believe to be just as truly rubella as is the more common macular form. In this connection, we should not lose sight of the fact that there is always a tendency for the lesions in this disease to coalesce, even where the eruption is primarily of the discrete macular type, and a superficial examination in such cases may also lead one to make an erroneous diagnosis of scarlet fever. Let me remind you that coalescence of the rash in rubella does not indicate any undue severity of the attack, as a similar condition in real measles frequently does.

The color of the rash is light pink, and when fresh is much lighter than the fully developed

rash of either scarlet fever or measles. There is no real conjunctivitis, but the conjunctiva may be slightly injected. The face looks puffy, the eyelids especially so; the eyes are watery, the nose runs and the observer gets the impression that the patient has just been crying. There is no photophobia; there is sometimes a slight hoarseness and a hardly noticeable cough, and there is always more or less sneezing at the onset of the attack.

Examination of the chain of lymphatics behind the sterno-mastoid muscle reveals a very significant condition. These glands while much enlarged, are practically painless, and the individual glands stand out prominently, being outlined to the touch as though they were beads arranged under the skin. A large isolated gland is always found at the tip of the mastoid process, and this is, I believe, pathognomonic of the disease. It is often stated by adults that they noticed this enlarged gland twenty-four hours before the appearance of the other symptoms, and it is more than likely that it is a regularly premonitory disturbance. Other groups of lymphatics may be enlarged, though nothing unusual is noted about the gland at the angle of the jaw.

The throat is red but does not call forth complaint from the patient. The uvula is congested and this congestion spreads up on the soft, and sometimes on the hard palate. On either side of the median line of the palate may be seen *Forscheimer's* spots. These consist of small, dark red granular bodies on the lighter mucous membrane, or as *Forscheimer* himself describes them, "small discrete dark red, but not dusky papules." These spots make their appearance early in the attack, and fade with the rash. The tongue is lightly coated and may possibly display some red papillae. The coating in some instances clears off, leaving the tongue a pale red, and this change naturally adds to the perplexity of the physician, who possibly has already been in doubt as to whether he is dealing with scarlet fever or rubella. It can be affirmed in this connection that the rubella tongue is never the clear, moist, beefy-red tongue, studded with papillae, which is well known as the *strawberry* tongue of scarlet fever.

The temperature will range between 99 and 101 degrees, seldom higher. Furthermore, it does not outlast the full development of the rash. The pulse is moderate, often not at all increased in rate, a notable fact, considering the marked cutaneous disturbance. Very rarely vomiting is said to occur, but this is a symptom which, when present, may well furnish food for reflection as to the correctness of our diagnosis. No emphasis seems to be laid in the literature bearing on this subject upon the itching which is a concomitant of the rash, but the writer well remembers the intolerable pruritus and the intense burn-

ing of the skin which tortured him when he had this disease as a child.

Desquamation is not often seen; when observed, it is fine and branny. In some of the intense eruptions, however, it can be extensive and profuse. The question of second attacks frequently comes up in this, as in the other acute exanthemata. The writer for many years checked up on the erroneous differentiations in the realm of eruptive diseases for the Department of Health, and while doing this work he observed the frequency with which non-contagious eruptions were diagnosed as one of the contagious diseases: it requires, therefore, a lot of corroborative evidence to make him believe that second attacks of rubella or any other eruptive disease are at all common.

As to the blood picture, it is said that the leucocytes are increased in number and the eosinophiles are diminished or absent during the stage of eruption, and I have seen it stated that there is a definite increase of lymphocytes, even preceding the appearance of the rash.

Sequela and complications are rare. As in the other infectious diseases involving the skin or the respiratory tract, the kidneys, ears and lungs may be attacked, but I have personally never seen or heard of a single instance of such complications in rubella.

Diagnosis: We may reasonably expect to find the following combination of symptoms:

1. Sudden onset, with signs of a cold in the head, the eyes being suffused and the nose running.
2. Moderate rise in temperature and possibly in the pulse rate.
3. Throat congested, but not troublesome, and the palate studded with Forscheimer's spots.
4. A rash, generally macular in character and pink in color, appearing early, spreading rapidly and fading just as rapidly. It markedly involves the face, is especially prominent in the circumoral area, and has a strong tendency to coalesce.
5. A much enlarged post cervical lymphatic chain, with one gland standing out prominently at the tip of the mastoid process.
6. The patient withal, is obviously not very sick.

Such an association of symptoms means rubella, But in addition to the picture drawn here, to those familiar with the disease there is even in atypical attacks an indefinable something which in most instances gives one his clue at a glance.

In discussing differential diagnosis, it may be said that the various toxic rashes and indeed scarlet fever and measles can usually be eliminated by careful study of the case. The latter

two diseases, however, are so frequently mistaken for rubella that they call for special consideration. Taking up first,

Scarlet Fever: The fact must be emphasized that the modification of the character of the attacks of scarlet fever in the last few years, taken in conjunction with the undoubted similarity of many of its signs and symptoms to those found in rubella, has laid an added burden of vigilance upon the conscientious diagnostician. In scarlet fever, however, the onset is liable to be more stormy and may be accompanied by vomiting; the throat is invariably truly congested; the pulse very much increased in rate, in proportion to the symptoms present; the temperature is higher, and drops by lysis as a rule, in contrast to its rather sudden fall in rubella; the rash is distinctly punctate, does not markedly involve the face, there is circumoral pallor, and the eruption fades deliberately; the lymphatic gland at the angle of the jaw is always enlarged and generally tender in scarlet fever, but there is no involvement of the post-cervical chain, nor of the gland at the tip of the mastoid, so characteristic of rubella; finally, desquamation always occurs in scarlet fever.

Measles: The principle points to bear in mind in differentiating measles from rubella are as follows: There is in measles a prolonged prodromal period; the rash is much slower in appearing, in developing and in disappearing; the patient is quite evidently ill, the constitutional disturbance being severe; there is marked conjunctivitis and a distinct bronchitis; there is a leucopenia, and last and most important, there is the Koplik spot, the most outstanding and dependable single sign in the whole field of eruptive diseases.

In conclusion, let it be admitted that in spite of all that has been said, and even though you may be the happy possessor of a practical experience that extends over many years, you will more than once meet with a case of eruptive disease, the identity of which at first glance appears shrouded in mystery. It may resemble rubella, or scarlet fever, or measles; or it may exhibit signs characteristic of each of these affections, and one cannot definitely tie himself down to a decision. Dr. William L. Somerset, at whose feet the writer sat for many years, and from whom he learned practically all he knows about this branch of medicine, very wisely recommended that in such a situation the patient should be isolated over night and looked over again next morning. This harms no one, and it is remarkable how diagnostic difficulties, that appear insuperable today, can vanish into thin air by tomorrow.

ALOPECIA ASSOCIATED WITH HYPOTHYROIDISM IN A CHILD

By I. NEWTON KUGELMASS, M.D., NEW YORK, N. Y.

From the Department of Pediatrics, the Fifth Avenue Hospital, New York

ALOPECIA is a rare condition in childhood requiring systemic study for diagnosis and therapy. It may be a congenital developmental anomaly characteristic of certain families or it may appear as an early manifestation of progeria or infantilism. It may be a manifestation of thyroid dyscrasia early in infancy or approaching puberty. It may be the only clinical expression of lues or the end effect of an infectious disease; it may be the result of a post-inflammatory fungus infection or a non-inflammatory microspore. It is never an expression of nutritional deficiency as in deprivation of vitamin G in experimental animals or of an anxiety neurosis as is the case in adults.

General alopecia of the scalp in a boy of nine is indeed a rarity. It may be the result of an anomaly of development but usually the loss of hair over the occiput is partial and acquired. In luetic the anterior of the scalp is frequently free from hair; in severe seborrhea of the scalp the loss of hair may be extensive; in acute infectious diseases it is less likely to affect the hair in children than in adults; in hypothyroidism the hair is scanty and dry and brittle. Fungus infections are the more common offenders, favus forming light yellow flakes around the hair follicles which on healing result in scarring and even permanent baldness without affecting the rest of the body. Microsporon occurs on the scalp without inflammatory changes producing grey scaly foci. The hair becomes dull, breaks readily and the alopecia is necessarily transient. The non-inflammatory trichophytosis spreads readily amongst children. It is characterized by small desquamating foci from which the hair protrudes.

When hair is shed after reaching the limit of its existence the epithelial cells surrounding the hair papillae continue to multiply in the formation of new hair. Alopecia results from a failure of the blood vessels of the papillae to furnish the required nutrition or from the dysfunction or destruction of the epithelial cells as a result of failure of endocrine and sympathetic stimuli essential for their functioning. Systemic disturbances must needs be included in a fundamental consideration of the etiologic factors involved in the progressive development of alopecia in children. It must be determined to what extent the normal growth stimuli are interfered with before the problem is considered local in origin.

R. F., an Italian boy, nine years of age, began suddenly to lose his hair from the posterior aspect in June, 1927. This loss continued to

become manifest in well defined areas throughout the head until complete alopecia occurred in the course of that year. Treatment for two years in various dermatological clinics by local applications and ultra-violet irradiation was without avail. At a general hospital the child was considered as a glandular problem with an undescended testicle as the etiological factor. This was corrected surgically without any subsequent effect upon bodily growth of hair. Each new therapeutic procedure proposed, whether external or internal, seemed to bring about a fine fuzz over the calvarium but no actual continued growth of hair.

We have approached the problem of alopecia in children from a systemic standpoint with striking results. Physical examination of the boy, first seen in August, 1931, showed nutritional dystrophy, coarse sallow skin and complete absence of hair from the scalp, eyebrows, armpits and genitals. The nasal breathing space was restricted, the mucous membrane congested and subsequent roentgenographic evidence of a sinusitis. The mucous membranes were pale and dry, the pharynx injected. There was a marked cervical and moderate general lymphadenitis. The thyroid was not palpable. The heart normal but slowed, the lungs clear, the spleen palpable at the costal margin, the liver not enlarged, the abdomen distended with gas and the musculature flabby. The hemoglobin was 65 per cent, the red cells 3.0 million, the white blood cells and differential normal. The blood sugar 78 mg. %. The basal metabolism minus 14. The complement fixation test negative. Smears for fungi negative.

The boy was put on a raw base-forming diet including raw milk, eggs, fruits, vegetables and meat reinforced with cod liver oil at each meal. The glandular therapy consisted of anterior pituitary (Zondek) 1 cc. subcutaneously and anterior pituitary 5 grs. and iodized thyroid $\frac{1}{2}$ gr. offered in ice water between meals. The anemia was corrected by the administration of 10 grains of ferric ammonium citrate, 1/100 of a grain of cobalt chloride and 1/100 grain of copper chloride. The scalp was massaged with cod liver oil at bedtime. Improvement was observed within a month, and a complete growth of hair was acquired after four months of the treatment.

The old teaching of Hebra considering the skin picture as a complete entity apart from the functional physiology of the rest of the body no longer maintains. The skin is the largest organ of the body and reflects in the thousand hair follicles to the square inch a multiplicity

of systemic factors. The case presented is illustrative of a dermatological error corrected by pediatric approach in the examination and treatment of the whole child.

Alopecia areata is a self-limited disturbance. But generalized alopecia associated with hypothyroidism only results in recovery after the readjustment of the endocrine mechanism. Four years of alopecia without semblance of acquisition of new hair following local treatment in contrast with the regaining of bodily hair fol-

THE APPEARANCES OF THE SCALP:

(A) One month after systemic therapy; (B) Two months; and (C) Six months.

lowing a systemic therapy for four months is certainly conclusive of the etiologic relationship of the alopecia with the condition of hypothyroidism.

The first determination of the basal metabolic rate gave a result of minus 19 while the second one taken before glandular administration gave a minus 14, as given above, and after four months of therapy the basal rate rose to plus 12. While the initial basal metabolic rate was not markedly low it has significance when interpreted with the clinical manifestations presented by the boy on first examination. While a basal metabolic rate of minus 14 in another boy of 13 would be at the border line of so-called low normal, obviously no such evaluation could be given

this problem. A single laboratory or clinical fact never determines the status of a clinical problem. The fine textured hair which was first lost at 9 was subsequently replaced by dry, coarse, and sparse growth which fell out again following local therapy. It was not until the combination of thyroid and pituitary treatment was instituted that a complete crop of hair was regained. Adolescence undoubtedly accelerated the rate of recovery. The present basal metabolic rate is plus 12.

The boy's activities, behaviour and psyche have undergone considerable change paralleling the six months of treatment. During the previous four years he had no considerable interest in activities, failed to participate in play with his friends, became markedly retarded in his school work, complained of cold to the extent of excessive interest in radiators and was not observed to perspire at all in comparison with previous performance. These negative developments have been transformed to the extent that the boy is now radiant, active and adept at his school work.

The raw base-forming dietary instituted as part of the therapy was based upon the rôle of the nutritional minutia in the maintenance of the metabolism of end tissues of the body. We have come to appreciate that during food deprivation the gross constituents of the dietary provide for the adequacy of the parenchymatous organs at least for the time being. During such periods of dietary limitation the end tissues—hair, nails, teeth and skin—undoubtedly suffer from lack of mineral minutia which have been demonstrated necessary for their function. It is for this reason, for example, that during illness there are kinks in the hair and ridges in the nails and teeth as indications of deprivation of minutia in minerals. It is on this ground that raw foods were advocated for the continued inclusion of those mineral elements that are most apt to be missed in the daily dietary.

NEW YORK STATE JOURNAL OF MEDICINE

Published semi-monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication.

THE PHYSICIAN AS A HOST

What is the secret of a doctor's well deserved popularity? One answer is found in this paraphrase of a full-page advertisement in the leading New York dailies

"His guests will find that he knows the answers. The NEW YORK STATE JOURNAL OF MEDICINE is behind the scenes with him giving him the answers to every phase of his active life."

The family doctor is the host to the patients whom he visits or receives. They judge him by his ability to answer their verbal questions and to satisfy their unexpressed longings for life-giving truth. The nine regular departments of the Journal are balanced in size and content so as to enable the doctor to be the satisfying host as well as the gentle healer.

MEDICAL RESEARCH ON LIVING ANIMALS

The New York Anti-Vivisection Society and the New York State Committee Against Vivisection have announced an intensive effort during the next session of the State Legislature to pass a bill to prevent the use of dogs in animal experimentation. Their action is doubtless based on sincere sympathy for dogs engendered by a personal sentimental attachment to one or more of them. However, stripped of emotionalism and reduced to essential elements, the members of the New York State Legislature must decide this question in a common sense way as to what is best for the public and the State.

One alternative is to retain the existing law and the universally accepted rules of procedure which have proven quite sufficient to prevent animal experiments in unauthorized places or cruelty in any form; to uphold the tradition of research and education established the world over by universities of all lands and scientists of all branches these hundreds of years; and to allow untrammelled the continued progress by research workers in the interest of public health and medical progress.

The other alternative is to yield to the desires of the emotionalist, and to stultify the very men who are responsible for the brilliant achievements which have lessened human suffering and prolonged human life, and to ignore the prominent leaders of education and science who are the heads of our universities and constitute boards of regents.

If the citizens of our commonwealth are put

in full possession of the facts, there is but one logical conclusion possible and that is, that the scientist must not be hampered in his work in any way.

In the meantime, however, these well meaning people are flooding the State with arguments based on sentimentality and endorsed by a few physicians evidently activated by similar emotions.

The outstanding facts of uncontrovertible achievements in medical progress due directly and solely to animal experiments on dogs, and for which purpose no other animal was suitable, are well set forth in an article on page 1354 of this Journal.

This present effort to restrict research and hamper progress is not new. In the past the medical profession of New York State has fought this battle in the legislature unaided, and we have had little difficulty in convincing the representatives of the people of the merits of our cause.

Now that the proponents of the restrictive measure are using means other than those concerning the need of the dog in research, namely, political activity having to do with the election or defeat of candidates for the legislature, we must appeal to educators and influential citizens, not for purposes of political activity but solely for the dissemination of the truth.

It is the duty of the members of the Medical Society of the State of New York to do this, and we plead for your help.

COMMITTEE ON MEDICAL RESEARCH.

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

X-Rays—The leading article in this Journal of December, 1907, is entitled "The present status of the Roentgen Rays," by Dr. Arthur Holding of Albany, who says:

"The Roentgen rays are still the x - or unknown rays, although the generally accepted theory is that the wave lengths of this light are far shorter and their rate of vibration far more rapid than those of ordinary light. These short waves of light are destructive to the human organism, as witnessed by the development of carcinomata, and azoospermia among the x -ray operators. Therefore, today, the radiographer avoids all exposure to the rays. This has led to the passing of direct fluoroscopic examination.

"When we remember that the truest of all passions is blind, it is not to be wondered at that 'enthusiasm' has sometimes reported a recession of symptoms as a cure, or mayhap, has reported an improved case as cured. I have known of such instances among specialists other than elec-

tro-therapeutists. But it is today generally known that:

"1. The x -ray causes degeneration of epithelial tissues, especially those of the skin and its appendages.

"2. The x -rays cause endarteritis.

"3. The x -rays cause destructive of lymphatic tissue.

"Furthermore, the x -rays have proved curative in intractable or inoperable cases of tubercular adenitis, pruritus, acne, sycosis, lupus vulgaris, lupus erythematosus, spleno-myelogenous leukæmia, pseudo-leukæmia, and eczema. The rays are a specific cure for epidermoid cancers. While we are not willing to say that the x -rays are a specific cure for all cases of cancer and sarcoma, we must admit that they do have a beneficial effect in cases of malignancy to which the rays can be applied directly. It is our duty to increase this action rather than to deny its presence."

MEDICAL PROGRESS

The Treatment of Burns in Out-Patients with Reinforced Tannic Acid Dressings.—Over a period of six months J. H. Hunt and P. G. Scott have treated a series of 63 consecutive cases of minor burns, in the out-patient department of St. Bartholomew's Hospital, with a modification of the recognized tannic acid method. If the crust formed by the usual method is covered with a dressing and bandage it tends to soften, become septic and detached. This difficulty has been overcome by reinforcement of the crust, either with a thin layer of gauze, gauze and collodion, or collodion alone. In the majority of second and third degree burns the method of choice is to paint the burned area with a 5 per cent solution of tannic acid in water, and apply a dressing soaked in the same solution. No anesthetic is required. Next day when the dressing is removed the burn will be found covered with a thin brown crust, and the dressing is repeated. On the third and fourth day this crust is reinforced with collodion. The surface then remains hard and dry and the crust separates toward the end of the second week, exposing the new epithelium which has grown beneath it. For the first aid treatment of all burns and scalds the authors urge the use of dressings soaked in a 5 per cent solution of tannic acid in water (20 grains of the powder to an ounce of warm water). Vigorous cleaning and scrubbing are avoided, as these do more harm than good. The tannic acid solution is applied with a soft camel-hair brush instead of a spray, because with the brush exudates are wiped away, allowing the tannic acid direct access to the burned surface. The effect of reinforcement is entirely mechanical. It prevents separation of the crust at the edge where it is in contact with the skin and its organisms. The results with this procedure have been very encouraging, especially in burns of the face and hands which often give so much trouble.—*The Lancet*, October 8, 1932, ccxxiii, 5693.

Treatment of Malignant Diphtheria with Glucose and Insulin.—As the death rate from diphtheria in Leeds had been steadily rising, and the type of disease had become much more severe, with the result that treatment with antitoxin was often disappointing, Hester E. de C. Woodcock decided to attempt an auxiliary line of treatment by giving intravenous glucose together with intramuscular insulin. This treatment was suggested by Schwenker and Noel (1930) as a result of their researches into the disorders of carbohydrate metabolism occurring in diphtheria. The routine procedure consisted in giving, on admission, 20,000

units of antitoxin intramuscularly. Two or three hours later 20 to 40 c.c. of a 50 per cent solution of glucose in distilled water were given intravenously with 20,000 to 40,000 units of diphtheria antitoxin intravenously and 10 to 20 units of insulin intramuscularly. This treatment was followed by daily doses of antitoxin until the membrane began to clear, or at any rate ceased to spread. In the first few cases the glucose and insulin were given only occasionally, while in the later cases this medication was repeated daily. In all, 25 cases were treated and the results compared with 11 cases of similar severity in which antitoxin alone was used. The figures show that in the glucose-insulin cases the mortality rate was 68 per cent, in the antitoxin cases 81.9 per cent. In the glucose-insulin series the paralysis rate in the fatal cases was 29.4 per cent, in the toxin antitoxin series 33.3 per cent. In the recovered cases of the glucose-insulin series the paralysis rate was 87.5 per cent, in the antitoxin cases 100 per cent. While the series is too small to be of statistical value, the impression was that, after treatment with glucose and insulin, the discomfort and distress, even in patients who succumbed rapidly, were relieved. The author believes the treatment is worth while from this point of view alone. She emphasizes the fact, however, that continued intravenous medication is difficult and frequently impossible. The veins of small children are not always easy to negotiate, and in severe cases of all ages the veins collapsed very readily, especially as the disease advanced.—*The Lancet*, October 22, 1932, ccxxiii, 5695.

Diathermy Treatment in Nephritides.—Fresh interest in the treatment of nephritis by diathermy, says H. Cohen, has recently been aroused by the good results reported by Ewig and Gantenberg in acute cases. Opinions differ, however, as to the indications for the treatment, some authors recommending its use only in acute cases, others in chronic, and still others in both types of cases. Cohen accordingly treated 15 cases of nephritis with diathermy, among which were 1 acute case, 5 sub-acute cases, 8 chronic cases, and 1 case of nephrosis. The method employed was to give on every other day a 2-hour diathermy treatment with 3-3.5 ampères, using one electrode of 30.30 cm. on the abdomen and the other of 15.20 cm. on the kidney region, the patients having been previously prepared by bed rest and proper diet. In neither the 8 cases of

chronic nephritis nor in the single case of nephrosis was an effect worthy of note observed; but in 4 of the 5 subacute cases (2 of which are outlined by the author), the impression was gained that the course of the disease process was possibly shortened somewhat. In the single acute case, which was in a very critical condition following an angina attack, with complete anuria for 26 hours, the patient died in a state of uremia and cardiac insufficiency on the day following the treatment. It is extraordinarily difficult to form any exact judgment of the effect of diathermy upon subacute nephritis, since even with the use of such measures the course of the disease is very variable. If we take into consideration the fact of the rest in bed and the special diet, the judgment expressed here might be regarded as a more or less subjective one. It is clearly objective, however, in the cases of chronic non-hypertonic nephritis and in the case of nephrosis, in which, despite months of treatment administered, no visible effect upon the course of the disease could be observed. It is Cohen's opinion, on the basis of his own experience, that diathermy finds its chief indication in cases of delayed recovery from acute nephritis. —*Deutsche medizinische Wochenschrift*, September 30, 1932.

Arterial Resection and Ligation.—To test the correctness of his impression that resection of important arteries is better tolerated than their ligation, Pierre Stricker undertook a series of experiments in rabbits. For purposes of comparison the local peripheral temperatures were ascertained between the claws, after careful drying. After ligation of the principal artery of one paw and resection of the same artery on the other, a marked transitory drop in temperature was observed in both paws, but for some 2-3 weeks the temperature remained higher on the resected than on the ligated side, before equilibrium was restored. Thus in one animal the difference was 0.6°F . a few hours after operation, 1.9° 24 hours later, and 4.4° on the second day, in favor of the resected side, which for 10 days remained above 85°F ., while on the ligated side it was always below that figure. By the third week the two curves had merged in one. When operation was done lower down, on the femoral arteries, equilibrium was restored by the 15th day, but when done higher up, on the common iliac, it resulted in death of the animal from ischemia in 2-3 days. Hence it was necessary for this test to use 2 animals, tying the common iliac of one paw in one and resecting it in the other. The ligated animal developed moist gangrene and died on the 15th day; the resected one suffered only a dry gangrene of the extremity, and continued in excellent health. When two

younger rabbits were used for the same experiment, resection was so well tolerated that the animal did not even limp and there was merely a slight paresis of the claws for a few days. The difference in local temperature was 4.8° on the third day, 2.3° on the eleventh, and none after a month. The ligated animal, on the other hand, developed gangrene and had to be killed on the eighth day. In a third experiment, also on young rabbits, the resection caused so little disturbance that 3 days after operation one could not tell which side had been operated on, with a differential temperature of only 0.2° in favor of the non-operated side, whereas the difference in the ligated animal varied between 9.6° and 5.8° , an abscess developed and death ensued on the twentieth day. The difference of temperature between the two sides remains appreciable much longer in the ligated than in the resected animal, sometimes for as much as 8 weeks in the former, as against 1 week in the latter. These experiments show afresh the role of the periarterial sympathetic and the benefits obtainable through its suppression by arteriectomy. —*Lyon chirurgial*, September-October, 1932.

Treatment of Human Anthrax with Creolin.—According to Warringsholz, who is a veterinarian, human anthrax is found sporadically in all countries. In Germany it reached its low point in 1919 with 18 cases and 2 deaths, its high point in 1928 with 252 cases and 22 deaths, to fall again in 1931 to 118 cases and 11 deaths. Although for the last 30 years creolin has been extensively employed by veterinarians in their treatment of anthrax in cattle, Warringsholz, despite its good results, had failed until 1929 in his efforts to persuade physicians to make use of it as their first treatment in their human cases, owing to its supposed toxicity. Since that year two cases, of which he reviews the histories, have come to his notice in which a physician has consented to administer creolin externally and internally, as soon as the diagnosis was made. In an adult running a high temperature, the dosage should begin with an even teaspoonful (6-8 gm.) every 2 hours, preferably in cream on account of its disagreeable taste. Gelatin capsules are inadvisable, since their action is too slow in a disease where speed in treatment counts for everything. As the fever declines the intervals may be lengthened to 3 hours, giving a total of about 70 gm. a day, or, if proportioned to body weight, about 1 gm. per kilo. It is important not to discontinue treatment too early, since relapses are frequent. Administration should be continued for at least 1 week after the temperature has become normal. Creolin is superior to serum in its action and is much cheaper; it is without toxicity,

even in such large dosage as is called for in anthrax. For this reason it can be administered prophylactically in cases regarded as suspicious. It has the further advantage of being easily obtainable in any drug store, or if necessary a veterinarian can be appealed to for it. To those who might offer the objection that 2 cases prove nothing, that the first cure may have been due to a previous injection of neosalvarsan, and that the second case ran a mild course and would have recovered anyway, Warringsholz replies that in the first case, which was very severe, neither a drop of temperature nor any indication of improvement had followed the neosalvarsan injection, and in the second the appearance of fresh signs of inflammation a week after the carbuncle of the right arm had seemingly healed, would indicate that the case was not so mild after all. The thousands of animals cured by creolin in the course of the last 30 years afford sufficient proof of the specific action of creolin in anthrax. — *Münchener medizinische Wochenschrift*, September 16, 1932.

The Dangers of Serotherapy.—On the basis of 3 personal cases, G. Combi, writing in the *Schweizerische medizinische Wochenschrift* of September 10, 1932, emphasizes the need of caution in the use of serum injections in cases in which infection is merely suspected. That such injections should not be given lightly without assured data is evident from the occasional cases that have been published in which symptoms of paralysis have followed their administration. In most of the cases reported antitetanus serum, administered prophylactically, has been the offender; in some cases, antidiphtheria, and in exceptional instances antistreptococcus, antigonococcus or antituberculosis serum has been responsible. Practically all cases observed have been in adults. The usual order in which symptoms appear is urticaria, arthralgia, and, after a few days, paralysis. The most frequent localization is the brachial plexus, with violent pains in one or both shoulders, motor disturbances, functional impotence, and with muscle atrophy as a constant and dominating symptom, the reflexes being lost or greatly diminished, whereas sensibility is little if at all affected. It is the general opinion that the serum responsible for the disturbances acts through the heterogenous protein it contains. While the nature and mechanism of the lesions are not well established, the sudden appearance of the symptoms and the presence of urticaria make it probable that there is a vascular disturbance within the nervous tissue, but whether this is due to hemorrhage, thrombosis, interstitial edema, a simple congestion of the connective tissue, or some other mechanism is not yet clear. The

predilection of the paralysis for the superior radices of the brachial plexus seems due to a mechanical factor which Sicard found in the anatomical course of the nerve roots to the dura mater of the brachial plexus; these, being the shortest in length, would be the most readily compressed by edema of the epidural space. The subject is of some importance in its medicolegal aspect. If a paralysis develops in the course of a treatment, its relation to the serum is evident; but if, as is usually the case, the paralysis appears after a prophylactic injection of antitetanus serum, insurance companies may consider themselves obligated to compensate only for trauma, and not for the results of preventive measures.

The Spine Sign in Poliomyelitis.—L. Charles Rosenberg calls attention to the value of the spine sign in the preparalytic stage of poliomyelitis. The sign consists in definite resistance to anterior flexion of the spine, but unfortunately it is not present during the period of systemic invasion before the beginning of meningeal irritation. The sign can be elicited in an older child by standing him on the floor and asking him to bend over and touch his feet without bending the knees. At the bedside of a child with feverish symptoms suspicion will be aroused by noticing that the back is held rigid when the patient is told to turn over. In the case of an infant lying prone the feet may be grasped by the physician in one hand while the other hand is placed on its back; then the limbs are swung from side to side and are elevated, causing extension of the spine. With the physician's hand under the abdomen, upward pressure may be made while the legs are lowered, thus causing flexion of the spine which will be resisted if the maneuver causes pain. — *Archive of Pediatrics*, October, 1932.

Acute Bacterial Endocarditis.—Cadis Phipps reports the results of a study of 44 cases of endocarditis resulting from various forms of bacterial invasion. Of these 21 cases were due to *Streptococcus hemolyticus* of which 17 were in males and 4 in females, the ages of the patients varying from 11 to 74 years. In about 60 per cent of the cases there were evidence of old lesions, especially arteriosclerotic changes in the endocardium. In 11 cases, 9 male and 2 female, with ages from 2 to 70 years, the infecting agent was a staphylococcus. *Bacillus coli communis* was responsible for 5 cases, 3 male and 2 female varying in age from 13 to 75 years. In 2 cases, both females, aged 21 and 26 years, the gonococcus was the infecting agent. The meningococcus was responsible for 2 cases, one male and one female, age 20 and 21 years. One case of *Staphylococcus albus* was in a girl of 17 years. In one

case in a man of 31 years, ¹¹¹ with pneumonia, the infection was a double one—*Streptococcus hemolyticus* and *Staphylococcus aureus*. Finally, there was another case, in a man of 45 years, of double infection—*Staphylococcus aureus* and *Bacillus coli communis*. The diagnosis of acute bacterial endocarditis will rest upon a picture of sepsis arising in the midst of some acute or chronic infection, together with the appearance of murmurs, often in addition to preexisting ones. Blood cultures are useful, but a negative one does not exclude the possibility, nor a positive one prove the existence of a diseased valve. The prognosis is practically always fatal, but recovery might be possible in meningococcus endocarditis for which we have a specific serum. The treatment is almost entirely symptomatic (digitalis, salicylates, etc.) The author obtained a cure some years ago, following a blood transfusion, in two cases, but has never since seen any benefit from such a procedure. In meningococcus endocarditis only does serum treatment offer any hope of cure.—*The New England Journal of Medicine*, November 3, 1932.

A Study of the Pathogenesis of Myocardial Fibrosis ("Chronic Fibrous Myocarditis").—Madelaine R. Brown calls attention to much misunderstanding of the term "chronic myocarditis." For the clinician it means myocardial insufficiency, as evidenced by the poor quality of the heart sounds and decompensation; while the pathologist uses it to describe areas of fibrous tissue in the myocardium. A more accurate term would be "scarring of the myocardium" or "myocardial fibrosis." In a material consisting of 1,000 consecutive autopsies she found 110 in which were described areas of scar tissue in the myocardium. In these 110 cases myocardial scarring was associated with arteriosclerosis 59 times, with syphilitic aortitis 24 times, with rheumatism in 10 instances. Of the 12 remaining cases, 3 at least gave evidence of old healed rheumatism, 4 were cases of tuberculosis, 1 chronic nephritis, while 3 were in children in whom the process was quite different. Of the 110 cases 98 were plainly associated with arteriosclerosis, syphilitic aortitis, or rheumatism. In the series of 1,000 cases the clinical histories gave evidence of such infectious diseases as pneumonia, typhoid fever, diphtheria, scarlatina and malaria quite as often in the 890 cases without myocardial scarring as in the 110 cases with this lesion. It is therefore impossible to ascribe the scarring to these infections. In this series direct invasion of the heart muscle in syphilis and rheumatism played a minor rôle in the pathogenesis of myocardial scarring. None of the cases in the series gave evidence of having suffered the effects of any known toxin. Disease of the coronary arteries

was present in 70 of the 110 cases. The rheumatic group showed the least myocardial scarring. The arteriosclerotic cases, 59 of the 110 cases, showed every degree of narrowing of the coronary arteries, often with calcification and complete occlusion, in which terminal thrombosis played a part. The evidence in this series thus indicates that disease of the coronary arteries is the important agent in myocardial scarring ("chronic fibrous myocarditis").—*American Journal of the Medical Sciences*, November, 1932, clxxxiv, 5.

Acute Osteomyelitis in Children.—Cecil P. G. Wakeley, writing in the *British Medical Journal*, October 22, 1932, ii, 3746, quotes statistics from hospitals in the United Kingdom which indicate that acute osteomyelitis is a disappearing disease and is not as fulminating as formerly. This is due to the fact that the general health of children is much better. Tonsils and adenoids are removed at an early age, thus doing away with septic infection from the throat and many complications occurring after infectious fevers. In addition debilitating and deficiency diseases are treated very effectively. In all probability trauma plays no important part in the causation of osteomyelitis, though the text-books have always stressed it as an initial cause. In children osteomyelitis begins on the diaphyseal side of the epiphyseal plate, and over 50 per cent of the cases occur in the femur and tibia. The abundant blood supply to the growing end of the bone and its anatomical arrangement favor the occurrence of embolism which would cause devascularization of the bone adjacent to the metaphysis. As a diagnostic aid the x-rays are of little use in the early stages of the disease. If the surgeon waits until there is something definite in the x-ray picture, he will wait too long, and valuable lives will be lost. Every case of acute osteomyelitis requires immediate drainage, since any delay may result in extension of the primary focus to the medullary cavity. In the early stage this cavity is not involved and should not be opened as a routine measure. Simple trephining of the diaphysis just above the epiphyseal plate often is all that is required. In well-established cases the medullary canal must be opened and one-third of its circumference removed. The making of multiple drill holes down to the focus of infection is not an efficient method of drainage, as there is a tendency for granulations to fill up the holes and for pus to become pocketed beneath them. Wakeley is convinced that if the case is a late one and the whole of the diaphysis is involved, diaphysectomy is the only method to be adopted, followed later by a bone graft. In the after-treatment of these cases he recommends packing the gutter in the bone with antiseptic gauze and changing the dressing every other day. Immobilization in a plaster splint is essential.

LEGAL

THE SCOTTSBORO CASE

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

Seldom in the history of the administration of the criminal law in this country has a case caused such widespread comment or attracted so much public interest as the so-called Scottsboro case. The case made its way through the courts of Alabama and was carried to the Supreme Court of the United States on a writ of certiorari, and only a few days ago that court delivered its opinion in the matter. The decision of the highest court of the land relates to matters of such general interest and involves constitutional rights so fundamental, that it seems appropriate to consider the case at some length in these columns.

From the facts it appeared that on March 25, 1931, two young white girls were riding on a gondola car of a freight train in Alabama. They were in the company of some white boys who were likewise hitchhiking. There were a number of young negroes in adjoining cars, and while the train was traveling at a fair speed the blacks crossed into the gondola car where the girls were. In some manner a fight started between the whites and the blacks, and all of the white boys except one were either thrown or driven from the train by the negroes. According to the story told by the girls, each of them was then forcibly raped by six different negroes in turn. Word was sent ahead and when the train arrived at Scottsboro, Alabama, a sheriff's posse and a large crowd of people met the train and took into custody the negroes. Apparently a few of the negroes had made a getaway before the train was stopped. There was considerable excitement attendant upon the arrest of the negroes, and they were in such danger of mob violence that the sheriff called for the militia to assist in safeguarding the prisoners.

Six days after the crime was committed eight of the negroes were indicted for the crime of rape, and on the same day they were arraigned and entered pleas of not guilty. On April 6th, only six days after the indictment, the trial of the defendants began, the collective case against them having been severed so that they were tried in three groups. The juries found the defendants guilty. The Alabama law permits juries, in their discretion, upon a conviction for rape, to send the defendants to prison or condemn them to death. In the exercise of this discretion the juries imposed the death penalty upon all the defendants.

From the judgments of conviction appeals were taken to the Supreme Court of Alabama, which court affirmed the conviction of seven of the defendants and ordered a new trial as to the remaining defendant because he was under sixteen years of age and should have received special treatment as a juvenile delinquent. From the decision of the court affirming the conviction, there was a vigorous dissent by the Chief Justice.

The case had attracted widespread attention and various organizations became interested in the defense of this case, with the result that the case was carried to the Supreme Court of the United States on the ground that the defendants had been denied due process of law and equal protection of the laws under the Fourteenth Amendment to the Federal Constitution. Specifically, it was contended (first) that they were not given a fair, impartial and deliberate trial; (second) that they were denied the right of counsel; and (third) that negroes were excluded from the juries in the trial of their case. The highest court of the nation, with two of the Justices dissenting, reversed the conviction on the sole ground that the defendants had been deprived of their constitutional rights to the proper assignment of counsel. The other grounds of error were not considered by the court.

The defendants had been indicted and arraigned on the same day. On the day of the arraignment the defendants were apparently not asked by the court about counsel, or asked if they wished to communicate with friends or relatives. The court on that day stated that "all the members of the bar" were appointed for the purpose of the arraignment of the defendants. The responsibility for conducting the defense was not fixed upon any one member of the bar and was in fact not definitely fixed on any of the bar.

Six days after the arraignment the case was called for trial, and the trial court asked if the parties were ready to proceed. The district attorney answered in the affirmative and no one responded for the defendants. A certain Mr. Roddy, an attorney from Chattanooga, then addressed the court and stated that while he had not been employed in the case he had been consulted, and would like to appear as counsel associated with such counsel as the court might appoint to represent the defendants. A discussion ensued among the trial judge, the said Mr. Roddy and various members of the bar in a

very casual manner, in the course of which Mr. Roddy stated that he had come to Alabama, though inexperienced in Alabama practice, to help the defendants if possible. One of the members of the local bar finally agreed to "help do anything" he could for Mr. Roddy, the Chattanooga lawyer. The trial proceeded immediately with this very vague arrangement as to counsel for the defendants. Clearly, whatever may have been the merits of the case, the defendants were at a disadvantage. Counsel representing them went into the case practically without preparation or without investigating the facts. As the opinion of Mr. Justice Sutherland, who delivered the majority opinion for the Supreme Court of the United States, states:

"The defendants, young, ignorant, illiterate, surrounded by hostile sentiment, haled back and forth under guard of soldiers, charged with an atrocious crime regarded with a special horror in the community where they were to be tried, were thus put in peril of their lives within a few moments after counsel for the first time charged with any degree of responsibility began to represent them."

The court's further comment is interesting:

"It is true that great and inexcusable delay in the enforcement of our criminal law is one of the grave evils of our time. Continuances are frequently granted for unnecessarily long periods of time, and delays incident to the disposition of motions for a new trial and hearings upon appeal have come in many cases to be a distinct reproach to the administration of justice. The prompt disposition of criminal cases is to be commended and encouraged, but in reaching that result a defendant, charged with a serious crime, must not be stripped of his rights to have sufficient time to advise with counsel and prepare his defense. To do that is not to proceed promptly in the calm spirit of regulated justice but to go forward with the haste of the mob."

After having concluded that the defendants had been denied their rights to counsel, the court in its opinion proceeded to explain the reasons why such a denial of the right to counsel contravened the "due process clause."

The court showed that the fundamentals of our system of government, starting with the colonies prior to the War of the Revolution, and as embodied in the United States Constitution, had ever jealously guarded the rights of a defendant charged with a crime. The Sixth Amendment to the Federal Constitution which was cited by the court reads as follows:

"In all criminal prosecutions, the accused shall enjoy the right to a speedy and public trial, by an impartial jury of the State and district wherein the crime shall have been committed, which district shall have been previously ascertained by law, and to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining Witnesses in his favor, and to have the Assistance of Counsel for his defense."

The court quoted the famous words of Webster that by "the law of the land" is intended "a

law that hears before it condemns," and discussed the requirements of a hearing such as is required under due process of law as follows:

"What then does a hearing include? Historically and in practice in our own country at least, it has always included the right to the aid of counsel when desired and provided by the party asserting the right. The right to be heard would be, in many cases, to little avail if it did not comprehend the right to be heard by counsel. Even the intelligent and educated layman has small and sometimes no skill in the science of law. If charged with crime, he is incapable, generally, of determining for himself whether the indictment is good or bad. He is unfamiliar with the rules of evidence. Left without the aid of counsel he may be put on trial without a proper charge, and convicted upon incompetent evidence, or evidence irrelevant to the issue or otherwise inadmissible. He lacks both skill and knowledge adequately to prepare his defense even though he have a perfect one. He requires the guiding hand of counsel at every step in the proceedings against him. Without it, though he be not guilty, he faces the danger of conviction because he does not know how to establish his innocence. If that be true of men of intelligence, how much more true is it of the ignorant and illiterate, or those of feeble intellect? If in any case, civil or criminal, a State or Federal court were arbitrarily to refuse to hear a party by counsel, employed by and appearing for him, it reasonably may not be doubted that such a refusal would be a denial of a hearing, and, therefore, of due process in the constitutional sense."

The court in concluding that the judgments of conviction should be reversed and new trials granted the defendants, stated in part:

"All that it is necessary now to decide, as we do decide, is that in a capital case, where the defendant is unable to employ counsel, and is incapable adequately of making his own defense because of ignorance, feeble-mindedness, illiteracy, or the like, it is the duty of the court, whether requested or not, to assign counsel for him as a necessary requisite of due process of law; and that duty is not discharged by an assignment at such a time or under such circumstances as to preclude the giving of effective aid in the preparation and trial of the case. To hold otherwise would be to ignore the fundamental postulate, already adverted to, 'That there are certain and immutable principles of justice which inhere in the very idea of free government which no member of the Union may disregard.' In a case such as this, whatever may be the rule in other cases, the right to have counsel appointed, when necessary, is a logical corollary from the constitutional right to be heard by counsel."

The court further stated:

"Let us suppose the extreme case of a prisoner charged with a capital offense, who is deaf and dumb, illiterate and feeble-minded, unable to employ counsel, with the whole power of the State arrayed against him, prosecuted by Counsel for the State without assignment of counsel for his defense, tried, convicted and sentenced to death. Such a result which, if carried into execution, would be little short of judicial murder, it cannot be doubted would be a gross violation of the guarantee of due process of law; and we venture to think that no Appellate Court, State or Federal, would hesitate so to decide. * * The duty of the trial court to appoint counsel under such circumstances is clear, as it is clear under circumstances such as are disclosed by the record here; and its power to do so even in the absence of a statute, cannot be questioned. Attorneys are officers of the court and are bound to render service when required by such an appointment."

"The United States by statute and every State in the Union by express provision of law, or by the determination of its courts, make it the duty of the trial judge, where the accused is unable to employ counsel, to appoint counsel for him. In most states the rule applies broadly to all criminal prosecutions. In others it is limited to the more serious crimes and in a very limited number to capital cases. A rule adopted with such unanimous accord reflects, if it does not establish, the inherent right to have counsel appointed at least in cases like the present, and lends convincing support to the conclusion we have reached as to the fundamental nature of that right."

It should be kept in mind that the merits of

the case were not before the Supreme Court of the United States. It is difficult to imagine a more reprehensible crime than that of rape, but whether or not the defendants were guilty of the crime charged, they were entitled to have their constitutional rights safeguarded by the court. Far more than the individual case was involved in this appeal, and the highest court of our land demonstrated once again its zealotry in safeguarding and protecting the constitutional rights of every citizen, irrespective of race, creed or color.

CLAIMED NEGLIGENT PRENATAL CARE AND DELIVERY

A doctor engaged in general practice was consulted by a young married woman with respect to her condition of pregnancy. The doctor examined her and found her to be in about the sixth month and that apparently her condition was normal. He advised her to return in about a month and at that time to bring to him a specimen of her urine.

She did not return, or communicate with him, however, until about ten days after the date her delivery should have been due in normal course when he was called to examine her at her home. He found that the child was alive and in normal position in the womb, and that from her condition the patient would deliver in about a week. The doctor directed her to notify him when labor started.

Five days later the doctor was again called to the patient's home and an examination showed no dilatation. The following morning examination revealed one finger dilatation, and that afternoon and evening the doctor examined her but found no further dilatation. The doctor at that time decided that her condition was not progressing normally and he arranged for her to enter a hospital and called an obstetrician into consultation on the case. The said consultant advised that a cesarean section was necessary and performed the said operation. The child when delivered was not breathing although his heart was beating. The general practitioner, who was assisting at the cesarean delivery, gave respiration to the child with oxygen, also hot and cold tubs and adrenalin into the heart directly. The child be-

gan to breathe, his color improved and he became normal in about two hours, at which time the doctor left the child in care of a nurse.

Together with the obstetrician, the general practitioner continued to care for the mother who, however, failed to improve normally from the cesarean operation but developed pulmonary oedema, intestinal stasis, sepsis and her kidneys refused to function. Although enemas were administered and irrigation done, the doctor and the others called by him to treat the woman were unable to do anything to cause her kidneys to function, and finally seven days after delivery the patient died. The child, which had been apparently in good condition when the doctor turned him over to the nurse, had failed to continue to improve and had died late the day of his birth.

Suit was thereafter brought against the general practitioner by the husband as administrator of his wife's estate to recover damages, charging the defendant with having negligently caused the death of the wife. His chief complaint was that the doctor, in his care of the patient during her period of pregnancy, was negligent in failing to discover that she was suffering from kidney trouble.

After the action had been noticed for trial and had appeared on the calendar for trial, the plaintiff's attorney, apparently realizing that he was unable to prove by medical testimony that the doctor had failed to follow proper practice in his treatment of the woman, voluntarily discontinued the action.

NEWS NOTES

ANNUAL MEETING ARRANGEMENTS

PRELIMINARY ANNOUNCEMENT.

The committee on Arrangements of the Medical Society of the State of New York has outlined its plans for the One Hundred and Twenty-Sixth Annual Meeting of the Society to be held April 3, 4 and 5, 1933, in the Waldorf-Astoria Hotel, Park Avenue and Fiftieth Street, New York City. The times and places of the ten previous annual meetings are shown in the following table:

Time	Place	President
1923 May 21-24	New York	Arthur W. Booth
1924 April 21-23	Rochester	Orrin S. Wightman
1925 May 11-14	Syracuse	Owen E. Jones
1926 March 29-April 1	New York	N. B. Van Etten
1927 May 9-12	Niagara Falls	George M. Fisher
1928 May 21-23	Albany	James E. Sadlier
1929 June 3-6	Utica	Harry R. Trick
1930 June 2-4	Rochester	J. N. Vander Veer
1931 June 1-3	Syracuse	William H. Ross
1932 May 23-25	Buffalo	W. D. Johnson

The place of this year's meeting will be the Waldorf-Astoria Hotel. This hotel has abundant space for the meeting and exhibits, as was demonstrated by the meeting of the American College of Surgeons last year. The date is considerably earlier than usual, owing to the meetings of numerous other medical societies, especially those of national importance.

The general features of the meetings of previous years will be preserved, and some new ones will be introduced.

Clinic Day: The opening event of the annual meeting will be a clinical day on Monday, April 3, when leading clinicians of New York City will conduct clinics in several hospitals in both the morning and the afternoon.

House of Delegates: The House of Delegates will meet at two o'clock on Monday, April 3, and will continue in the evening and the following morning. The members will dine together in the Roof Garden during the recess between the two sessions on Monday.

Scientific Sessions: Dr. Arthur J. Bedell, Chairman, and his associates on the Committee on Scientific Work, are arranging the programs of the eight scientific sections, whose meetings will be held on Monday and Tuesday, April fourth and fifth.

A general session will be held in the Grand Ball Room on the afternoon of Tuesday, April fourth. The full programs of all the scientific sessions will be published a month before the meeting.

Dinner and Anniversary Meeting: An Anniversary Meeting of the Medical Society of the

State of New York must be held in accordance with the Charter of the Society. This meeting will take place in connection with the annual dinner, which will be held on the evening of Tuesday, April fourth. The Committee expects to secure speakers of national reputation.

Public Meeting: Tentative plans are being considered to hold a public meeting on the evening of Wednesday, April fifth, in the Grand Ball Room.

Scientific Exhibits: The features of the scientific exhibit, which has proved successful in past years, will be repeated in an amplified form. The committee in charge for its arrangement and management consists of Dr. Arthur J. Bedell, Albany, Chairman; Dr. Frederic E. Sondern, New York; Dr. E. R. Cuniffe, Bronx, and Dr. P. E. Bechet, New York.

Commercial Exhibits: A pleasing feature of the annual meeting will be the exhibit of medical wares shown by manufacturers and dealers. The importance of this exhibit is equal to that of any other feature of the annual meeting, for without the modern tools of his profession, and his instruments of precision, the physician would be compelled to practice the medicine of his forefathers. Ample space and a convenient arrangement of booths will contribute essentially to an ease of demonstration of the wares.

Committees: The scientific phases of the annual meeting are in charge of the Standing Committee on Scientific Work, consisting of the following members:

Dr. Arthur J. Bedell, chairman, Albany
Dr. Edward C. Reifenshtein, Syracuse
Dr. Edward R. Cuniffe, Bronx
Dr. Edward C. Hughes, Syracuse
Dr. Brewster C. Doust, Syracuse
Dr. Davis F. Gillette, Syracuse
Dr. Daniel R. Reilly, Cortland
Dr. Henry W. Williams, Rochester
Dr. Paul E. Bechet, New York
Dr. Frederic E. Sondern, New York

Committee on Arrangements: The general arrangements for the annual meeting are under the Standing Committee of Arrangements assisted by a local committee of the following physicians living in Greater New York:

Dr. Samuel J. Kopetzky, Manhattan
Dr. William Klein, Bronx
Dr. Edward R. Cuniffe, Bronx
Dr. Edward C. Podvin, Bronx
Dr. Terry M. Townsend, Manhattan

Dr. David J. Kaliski, Manhattan
Dr. Iago Galdston, Manhattan
Dr. John J. Masterson, Kings
Dr. Charles H. Goodrich, Kings
Dr. Alex N. Thomson, Kings
Dr. Frank D. Jennings, Kings
Dr. H. P. Mencken, Queens
Dr. Carl Boettiger, Queens
Dr. Edward A. Flemming, Queens
Dr. James R. Reuling, Queens
Dr. Andrew J. McGowan, Richmond

The following committee has charge of the plans for press releases and publicity generally.

Dr. Chas. Gordon Heyd, President, Medical Society of the State of New York

Dr. Frederic E. Sondern
Dr. Iago Galdston
Dr. George W. Kosmak
Dr. Clarence G. Bandler
Dr. John A. Gerster
Dr. Samuel J. Kopetzky (ex-officio).

Publicity: The annual meeting of the Medical Society of the State of New York is an event of civic importance, and the need of organized publicity of the proceedings has been demonstrated in past meetings. General publicity of this year's sessions will be handled by Mr. Dwight Anderson. Radio Publicity will be handled by Dr. Iago Galdston, and Mrs. R. S. Hirshman.

The Committee on Arrangements,
SAMUEL J. KOPETZKY, *Chairman.*

SECOND DISTRICT BRANCH

The twenty-sixth annual meeting of the Second District Branch of the Medical Society of the State of New York, composed of the four counties on Long Island, was held in the Garden City Hotel, Garden City, Long Island, on the afternoon and evening of Thursday, November 12, 1932. The meeting was highly successful owing to the efforts of the President, Dr. Louis A. Van Kleeck; the Secretary, Dr. Alec N. Thomson, of Brooklyn, and the Chairman of the Scientific Committee, Dr. Irving Gray, of Brooklyn. Seventy members were present at the scientific session, which was held in the afternoon, and two hundred at the supper meeting in the evening when many ladies were present also.

The ladies were entertained during the afternoon by a lecture on contract bridge by Janet A. Krantz, after which demonstration games were played.

Garden City is in the aviation section for Greater New York, and several members saw Long Island from the air in a transport plane.

The scientific session consisted of a symposium on the subject: "Diseases of the Bones and Joints," presented from six points of view of six physicians, all Long Island practitioners:

"Internal Medicine," Dr. Tasker Howard, Brooklyn.

"Surgery, Diagnosis and Treatment," Dr. Frank S. Child, Port Jefferson.

"Roentgenology," Dr. Richard A. Rendich, Brooklyn.

"Pediatrics," Dr. Walter C. A. Steffen, Flushing.

"Physical Therapy," Dr. Jerome Weiss, Brooklyn.

"Arthritis," Dr. George E. Anderson, Brooklyn.

The papers were highly practical and interesting and will be published in the *Journal*.

The after-dinner speaking in the evening was

of unusual practical value both in subject and presentation.

Dr. Henry F. Vaughan, Commissioner of Health of Detroit, Michigan, described that city's plan of cooperation between the Department of Health and the family doctors. The Department does not conduct free clinics, but sends patients to their family doctors. It took up the subject of diphtheria immunizations first, and secured the approval and cooperation of the County Medical Society in a campaign to get the physicians to agree to set aside certain office hours when they would give the immunizations at one dollar for each injection. Each signed a card stating the days and hours on which he would give the immunizations at reduced rates. But he could make his usual charge to those who came at other hours. If a patient could not pay, the doctor gave the treatment and sent the bill to the City Health Department which paid it at half the usual rate.

There are about 1,100 doctors in Detroit, and 750 signed the agreements early in the campaign. The City Department then canvassed the remainder principally by means of public health nurses, and secured the agreements from 300 more. Practically all the physicians in Detroit are cooperating in the plan.

When a child needing an immunization is brought to the City Department of Health, the city physician refers the mother to a list of co-operating doctors near her home, and afterward checks up the case with a call from the public health nurse.

Dr. Vaughan described the results of the plan, and summarized the advantages. The doctors were benefited in four ways:

1. No free clinics.

2. It introduced them to well persons and encouraged them to do preventive practice among the well group.

3. It promoted cordial relationships of the doctors with the Department of Health and other groups doing preventive health work.

4. The doctors received pay for their work.

The Health Department benefited financially, for the cost of the preventive work has been far less than that of the hospital care of diphtheria cases before the preventive work was started.

Dr. Vaughan concluded with an outline of plans for introducing a similar method in dealing with smallpox and tuberculosis, and in periodic health examinations.

(A description of the Detroit plan is contained in the September, 1932, issue of the *American Journal of Public Health*.—EDITOR'S NOTE.)

Dr. Charles Gordon Heyd, President of the Medical Society of the State of New York, spoke on the subject, "The Stand the Organized Medical Profession Should Take." He said that the medical service available to the people of the State of New York was the first in the world. Its effectiveness may be appraised by the tremendous reduction in deaths and sickness and the lengthening of the years of life. Doctors of the United States give a million dollars worth of free treatment daily. They are the greatest givers in the whole land. The value of the free services of doctors in hospitals, if estimated at current rates, would exceed all other costs of running the hospitals. Dr. Heyd developed the unjustness of saddling this cost on a small group of citizens,—the doctors,—when it should be distributed over the entire community.

Dr. Heyd called attention to the great results of mass health work, meaning such activities as the purification of water, the disposal of sewage, and the pasteurization of milk. The next great advance in health work will be that doctors shall engage in the individual practice of preventive medicine, and shall be paid for it. The field is not merely in communicable diseases, but also in diabetes, heart disease, kidney affections, and other insidious conditions whose control are the hands of the *individual* rather than the community.

Dr. Frank L. Babbott, Jr., President of the Long Island College of Medicine, outlined the plans of the College in teaching preventive medi-

cine (directed to the individual), and community health (directed to the community). The College makes a personal approach to each student by means of a health examination; and at the end of the year it tabulates the records and presents the results to the class as a concrete example of actual conditions among a group whose members know one another intimately. Dr. Babbott believes that this method of approach will make a deep impression on the future practitioner of medicine.

Dr. Babbott also described the close cooperation of the Division of Preventive Medicine and Community Health with that of Internal Medicine, so that when a subject, such as typhoid for example, is taught, its epidemiology shall be taught as fully as the diagnosis and treatment of the sick patient.

Dr. Frederic E. Sondern, Chairman of the Committee on Research of the Medical Society of the State of New York, called attention to the urgent need of enlisting the support of every member of the State Legislature in opposition to any bills that may be introduced during the approaching session that will hamper medical progress by restriction on animal experimentation. (See this Journal pages 1354 and 1374.)

Dr. Sondern, who is also Chairman of the Committee on Insurance, urged the physicians to keep up the indemnity insurance sponsored by the Medical Society of the State of New York.

Dr. Orrin Sage Wightman, Editor-in-Chief of the NEW YORK STATE JOURNAL OF MEDICINE, gave a brief talk on the *Journal*, and asked for a show of hands by those who actually read its several departments, such as "Medical Progress" and "Book Reviews," and wish them to be continued. The members gave striking evidence of their desire to continue all the departments of the *Journal* in their present size and scope.

The officers elected were:

President, Louis A. Van Kleeck, Manhasset.

First Vice-President, Carl Boettiger, Richmond Hill.

Second Vice-President, Irving Gray, Brooklyn.

Secretary-Treasurer, Alec N. Thomson, Brooklyn.

SUFFOLK COUNTY

Annual Meeting: The one hundred and twenty-seventh annual meeting of the Suffolk County Medical Society was held in the Henry Perkins Hotel, Riverhead, on Thursday, October 27, 1932, with the Vice-President, Dr. J. H. Marshall, in the chair, and 35 members present. A business session was held from eleven to one o'clock, at which items which had been proposed by the

Comitia Minora were discussed. Luncheon was served in the meeting room, after which the scientific program was carried out. The meeting adjourned at four o'clock.

The Secretary, Dr. E. P. Kolb, reported that the Comitia Minora had met monthly excepting during the summer, and had spent much time in friendly, informal discussion of a number of top-

ics concerning the Society. The members felt that the discussions of specific topics by a small group of leaders would relieve the general meetings of the Society of unnecessary debates, and would enable the officers and committeemen to give prompt answers to questions which might be asked.

The discussions and conclusions of the Comitia Minora were printed in the monthly *News Letter* of the Society, and so the members would come to the meeting informed on the questions that were before the Society, and prepared to take intelligent action.

It was further felt that the method of procedure of the Comitia Minora would greatly facilitate the action of the Society at its general meetings.

(These expectations were amply justified by the facility and completeness of the action of the Society. The reports of the officers and committeemen were already known to the members, and the trend of the proposals was understood. The business was therefore transacted with facility and according to a time schedule.—*Editor's Note.*)

It was unanimously voted that the Library Service, offered by the Kings County Medical Society, be approved.

The Public Health Committee reported on a proposed plan of mosquito elimination based on that of Nassau County. While some malarial-carrying mosquitoes were breeding, there were no known cases of malaria. However, the Public Health Committee and the Comitia Minora had reported the opinion that mosquitoes generally constitute a public health problem, in that they are causing intense annoyance and discomfort to everybody in certain areas, especially low grounds.

The attitude of the committees was supported by the Society with one member dissenting on the technical ground that boards of health would find it utterly impractical to undertake mosquito elimination.

Dr. W. H. Ross, for the Economic Committee, reported on the cordial cooperation of the County Welfare Department with the physicians in the care of indigent patients. Dr. Ross also reported on the unsatisfactory relations of the insurance companies to physicians treating injured workmen, citing especially their insistence that workmen should consult a particular doctor designated by the companies. The Committee asked for the records of specific cases in order that it may take effective action. The Economic Committee without specific evidence is like a district attorney going before a grand jury without concrete evidence against the accused.

The Society gave its enthusiastic approval to the action of the Comitia Minora in appointing a committee to prepare a memorial dinner to seven of its members who had attained a half century of the practice of medicine. Drs. F.

Overton, Ross, and Healy were appointed to prepare such a dinner on Wednesday, November 9, at Leo's Inn, Patchogue.

Dr. Louis VanKleeck, President of the Second District Branch of the Medical Society of the State of New York, paid his official visit to the Society, and told of the splendid response to his plan of calling a conference of the chairman of each committee of the four county societies on Long Island. A conference of the chairmen of the Legislative committees had already been held, and one of the Economic committees will be held in the near future.

Dr. Alec N. Thomson, Secretary of the Second District Branch, and Medical Director of the Kings County Medical Society, spoke of some of the details in the leadership of the Suffolk County Society in demonstrating the good results of co-operation not only among the individual members, but also among the medical societies.

The Society adopted an amendment to the by-laws that the Society should meet four times a year instead of two, as at present.

The following new members were admitted to the Society:

Dr. Leslie T. Clary, Kings Park.
Dr. Charles Tainbor, Port Jefferson.
Dr. Cyril E. Drysdale, Northport.
Dr. Frank E. McGilvery, Smithtown Branch.
Dr. T. W. Falkner, Huntington (by transfer from Jefferson County).

The following officers were elected:
President, Dr. J. H. Marshall, Southold.
Vice-President, Dr. Louis A. Garben, Islip.
Secretary, Dr. E. P. Kolb, Holtsville.
Treasurer, Dr. Grover A. Silliman, Sayville.
Censors: Dr. W. H. Barnhardt, Central Islip.
Dr. J. Mott Heath, Greenport.
Dr. Burge P. MacLean, Huntington.

Delegates to the State Society:
Dr. C. C. Murphy, Amityville, and Dr. A. E. Payne, Riverhead.

Alternates:
Drs. J. H. Marshall and W. H. Barnhardt.
Representative on the Second District Branch Executive Committee:

Dr. W. H. Ross, Brentwood.
The presidential address of Dr. C. C. Murphy was read by the Vice-President, Dr. J. H. Marshall.

The scientific program consisted of two moving pictures.

Dr. Frank S. Child, Port Jefferson, showed two reels on the treatment of osteo-myelitis with fly maggots. These pictures had been taken by Dr. Child in the Mather Memorial Hospital and the St. Charles Hospital for Crippled Children, both situated in Port Jefferson. (See this *Journal*, August 1, 1931, page 937.)

Four reels on the subject of Cancer Research, made by Dr. Francis Carter Wood, Jr., were

shown by courtesy of the Suffolk County Cancer Committee. The opinion of the members was that while the subject was presented clearly and interestingly, yet it would be vastly improved if the repetitions and the non-essential scenes were eliminated so that the series could be shown within twenty or thirty minutes.

Anniversary Dinner: The anniversary dinner to the seven members of the Suffolk County Medical Society who had been in practice for half a century, was held on the afternoon of Wednesday, November 9, 1932, in Leo's Inn, Patchogue, with fifty-four members present. The honored guests were introduced after dinner in accordance with the following program, Dr. John B. Healy, Babylon, presiding:

OUR GUESTS

Seven honored guests today we see,
Wise men for half a century,
Our elders in the healing art,
Endeared by deed and warmth of heart.

Dr. George H. Donahue, Northport, P. & S., 1882, introduced by Dr. D. C. MacClymont, Northport:

Our Donahue—calm, true, and kind,
His modesty with skill combined.

Dr. William B. Gibson, Huntington, McGill, 1878, introduced by Dr. Burge P. MacLean, Huntington:

Our Gibson—patriarch and sage—
Whose wit and wisdom grow with age.

Dr. William A. Hulse, Bay Shore, Bellevue, 1883, introduced by Dr. William H. Ross, Brentwood:

Our friendly Hulse, financial fan,
Real doctor and true gentleman.

Dr. John Nugent, Southampton, University of Michigan, 1881, introduced by Dr. Morley B. Lewis, Sag Harbor:

To Nugent sly, our hats we raise,
By drollery he gives us praise.

Dr. George A. Smith, Superintendent of the Central Islip State Hospital, Bellevue, 1881, introduced by Dr. E. M. McCoy, Central Islip:

Our Smith, endowed with occult powers,
Boon comrade in our crazy hours.

Dr. Arthur H. Terry, Patchogue, P. & S., 1882, introduced by Dr. Frank Overton, Patchogue:

Our Terry wise, with equal skill
To make a poem or a pill.

Dr. Ralph Waldo, Westhampton, N. Y. U., 1882, introduced by Dr. R. E. Wyman, Westhampton Beach:

Our Waldo, who for rural joys,
Forsook the city and its noise.

The introducer of each guest presented him with a fountain pen on behalf of the Society.

Rev. Thomas W. Connolly, East Islip, gave an invocation before the dinner, and closed the exercises with an address on the priestly work of the doctor in comforting the sick.

The addresses, both introductory and responsive, were of a high order, and had been prepared with care. They will be published in the monthly *News Letter* of the Suffolk County Medical Society.

There were present five sons of the guests who are following their fathers' example and are practising medicine:

Dr. Gordon Gibson, Brooklyn.

Dr. Arthur H. Terry, Jr., New York.

Dr. John H. Nugent, Southampton.

Dr. Paul Nugent, East Hampton.

Dr. Paul Waldo, St. Luke's Hospital, New York.

The Suffolk County Medical Society had given a similar dinner to two of its members a half century in practice, Dr. Edwin S. Moore, Bay Shore, and Dr. Clarence C. Miles, Greenport, on December 11, 1925.

EDWIN P. KOLB, *Secretary*.

RENSSELAER COUNTY

At their regular meeting Thursday, November 10, 1932, the Medical Society of the County of Rensselaer were the guests of the Leonard Hospital.

A very interesting variety of cases was presented by the Medical and Surgical staff of the hospital. They were as follows:

1. Dr. Wm. Kirk: Case of Cardio-Vascular Disease with Cerebral Hemorrhage and Hemiplegia.

2. Dr. B. T. Baker: Reports of cases of Mastoiditis.

3. Dr. E. F. Connally: Case of Gas Bacillus Infection of arm following compound fracture of arm.

4. Dr. S. H. Curtis: Case of Diabetes Mellitus complicated by obliterating arteritis of leg with infection.

5. Dr. John Connor: Case of Toxaemia of Pregnancy.

6. Dr. E. M. Wells: Case of Gunshot injury to eye.

7. Dr. C. W. Hamm: Case of General Septicæmia of Blastomycetes origin with complications.

8. Dr. E. F. Connally: Case of Intestinal Perforation due to presence of a chicken bone.

The attendance was good and the discussion was active.

Two years ago the society abandoned the custom of having all meetings at the Health Center and also limited their papers to members of the society instead of an occasional or regular out-of-town speaker at each meeting.

The members have supported both plans about equally as well, the attendance averaging between one-fourth and one-third of the total membership.

At the close of the scientific program the nom-

inating committee reported the following as candidates for office during the year 1933:

President Emeritus, Dr. Osman F. Kinlock.

President, Dr. Warren St. John.

Vice President, Dr. Walter McShane.

Secretary, Dr. Clement J. Handron.

Treasurer, Dr. John F. Russell.

Delegates, Dr. A. J. Hambrook and Dr. John Reid.

Alternates, Dr. John J. Quinlin and Dr. John Connor.

Censors, Dr. C. W. Hamm and Dr. T. F. Judge.

It was announced at the close of the meeting that one of the speakers at our annual banquet would be the President of the Medical Society of the State of New York.

Meeting adjourned at 10:55 p.m.

WM. B. VAN AUKEN, *Reporter*.

FRANKLIN COUNTY

The regular annual meeting of the Medical Society of the County of Franklin was held in the Nurses' Lecture Room of the Alice Hyde Memorial Hospital, Malone, N. Y., November 2, 1932, with the President, Dr. H. B. Brown in the chair, and twenty-two members and seven visitors present.

The following officers were elected for the year 1933:

President, Dr. J. W. Kissane, Malone.

Vice-President, Dr. G. C. de Grandpre, Tupper Lake.

Secretary-Treasurer, Dr. G. F. Zimmerman, Malone.

Censor for three years, Dr. F. W. McCarthy, North Bangor.

Delegate to State Medical Society, Dr. C. C. Trembley, Saranac Lake.

Alternate, Dr. J. E. White, Malone.

Drs. Caroline Macartney Gorman and Philip William Gorman of Fort Covington were elected to membership.

The reports of the Secretary and Treasurer were read and approved.

Dr. R. G. Perkins brought up the County fee bill to be discussed by the Society. The following members joined in the discussion: Drs. Brown, White, Perkins and Stamatiades. All the speakers agreed that the fee bill for County Services was equitable; that no reduction should be countenanced, and that the members should unite in opposition to any curtailment of the present schedule, especially for tonsil operations.

Dr. White brought up the resolution of last annual meeting, petitioning the Committee on Legislation of the State Medical Society to foster

such legislation compelling insurance companies in the case of auto accidents to assume the payment of hospitals and physicians for attendance on the victims, such bills to be paid directly by them to the hospital and physicians concerned.

Dr. VanderVeer stated that the matter had been brought up in the Legislature last year, but had died in committee.

It was moved and seconded that the resolution be re-affirmed and sent to the Legislative Committee of the New York State Medical Society. Carried.

Dr. Albert Pfeiffer of the State Department of Health stressed the advantages of a County Venereal clinic. He outlined the steps to be taken in its establishment, and instructed the members in the procuring of material for examination by the State Department of Health.

It was moved by Dr. Perkins, seconded and carried, that a committee interview the Board of Supervisors regarding the establishment of a venereal clinic for the County of Franklin, exclusive of the Indian Reservation.

Drs. Van Dyke, Trembley, and Stamatiades were named for that committee.

The following papers were read at the Scientific Session:

1. Bronchoscopy—Dr. Warriner W. Woodruff, Saranac Lake.

2. Diagnosis and Treatment of Common Skin Diseases in General Practice, Dr. Marion B. Sulzberger, New York.

Dr. J. N. VanderVeer gave an interesting talk on the Economics of the medical profession.

G. F. ZIMMERMAN, *Secretary*.

THE DAILY PRESS

ANIMAL EXPERIMENTATION

The plea of Drs. Cannon and Drinker for freedom in animal experimentation, printed on page 1354 of this *Journal*, is supported by an editorial in the *New York Times* of November fifth, which says, in commenting on a lecture by Dr. Cannon before the New York Academy of Medicine:

"It is a pity that Dr. Cannon should find it necessary, in view of the bills annually introduced in Legislatures by well-meaning sentimentals, to review once more the achievements of

experimenters who have made it possible to stamp out epidemics.

"Dr. Cannon appeals to the public 'to sustain medical investigators in their endeavors' and not to leave the struggle with legislators to physicians alone. It has become a social duty to report contagious disease. Those in whom the spirit of progress lies will agree with Dr. Cannon that it is also a social duty not to interfere with legitimate animal experimentation."

SIGNS OF A HARD WINTER

The *New York Sun* of November 16 discusses some of the current predictions regarding the coldness of this winter. It refers to some accurate observations regarding the reliability of popular weather signs based on casual observations, and says:

"The few tests that have been made of nature as a weather prophet reflect no credit on her prophesying powers.

"One scientist recorded for twenty years the amounts of nuts stored by squirrels, and whether muskrats built their houses above ground, 'supposedly a sign of a hard winter. He found no connection between what the animals did in the fall and the kind of winter that followed.

"Southward migration of birds early in the fall means a hard winter, tradition says, but long

records of the biological survey show no connection.

"However, there are plenty of other natural 'signs' of a hard winter. Weeds may grow tall, to give birds and animals more food above the snow; the apple crop may be earlier than usual; barnyard fowls may grow a thick down under their feathers; owls may retire earlier than usual to the woods; the beaver may gather his winter food supply a month earlier than normal; the field mouse may make its burrows with the opening to the south; or onion skins may be thick.

"Any of these, according to ancient legend, are 'certain' signs."

A weather-wise farmer up-State says that he knows that this winter will be cold because women are wearing their dresses longer.

THE DETENTION OF THE DANGEROUSLY INSANE

The American system of considering a man innocent, or normal, until he has been proved guilty, or dangerously abnormal, sometimes works out disastrously, as is shown in the following editorial from the *Brooklyn Eagle* of October 29th:

"The act of a man in Queens who killed his grandson and himself the other day might have been prevented. Accounts indicate that he was held in the Kings County Hospital for some days and there treated for alcoholism and held under observation. He was released and three days later appears to have taken his own life and to have killed his grandchild from a motive of irrational resentment against his daughter-in-law, who had originally caused him to be taken away by the police.

"A few days ago occurred in the Middle West another release of a man who should apparently never have been let out from custody. He had

killed a woman some years before and had served a term in prison for the crime. Liberated in due course, he is alleged to have promptly killed another woman, the wife of a prison employe, seemingly from irrational motives.

"There is a background of other cases of the sort. Too many persons with an obsession to commit a violent act are taken into custody, kept for a time and let out, only to follow the obsession to its cruel end. There is need in many jurisdictions for more effective and particular study of persons detained for mental abnormality connected with violent impulses."

If the standards of evidence required by physicians before they operate or give treatments were those required by law courts, there would be a great decrease in law suits against doctors on the ground of neglect. It is lawyers, rather than doctors, who secure the freedom of those dangerously insane.

THE BRINKLEY CASE IN KANSAS

"The blood of the martyr is the seed of the Church"; and John R. Brinkley has posed as a martyr while he conducted his periodic campaign as a candidate for Governor of the State of Kansas. However, the real object of his campaign seems to have been to advertise himself as a "goat gland" specialist. The *NEW YORK STATE JOURNAL OF MEDICINE* discussed him in the issue of December 1, 1930, page 1425. This fall he achieved sufficient notoriety in his campaign for Governor to be discussed editorially in the dailies of New York City. The *New York Times* of August 31, described his methods in an editorial as follows:

"The doctor always gives a good show. It began with prayer by his pastor, who also led the singing. There were solos, music by a band, phonograph records, one of which startled the air with the doctor's campaign song, 'He's the Man.' There was a dance sponsored by the Brinkley Club at the close, 'with peanuts, popcorn, cracker-jack for the crowd.'"

He welcomes the violent attacks by the *Kansas City Gazette*, for they advertised his goat gland methods. Referring to the editor of the *Gazette*, he said, amid great applause:

"From time to time he has had great pleasure, I suppose, in taking the skin off of me. At times he has taken off my hide and my shirt and my pants—and I have enjoyed it. He helped me get elected Governor two years ago, and he is doing all he can every day now to help me get elected again."

The *Times* continues:

"The *Gazette* reporter curiously misunderstands the political psychology of the famous leech. Everybody wanted to see him and many were disappointed:

"The night was dark, the platform, which consisted of the candidate's own broadcasting truck with two sides let down to form a stage, was poorly lighted and it was close to the ground. He spoke from his wizard's cabinet in a sooth-sayer's mysterious voice. He came and went like a wrath, without handshaking, without personal contact with the common people, a man of mystery!

"That is his method. Apart, heard by multitudes but seen by few, he has built up his legend."

The real motive of Brinkley's campaign is revealed later on in the *Times* editorial, which says:

"Once a man came to the doctor's office with a copy of *The Gazette* containing a fluent and fire-tipped editorial. 'Dr. Brinkley,' said the visitor, 'this is the first time I have heard of you. You must have done something big to get Mr. White to write about you like he has, and if you will accept me as a patient I want to give you \$750.' If the *Kansas City Star* and the *Gazette* keep lambasting him, our medico is sure that he will get at least 500,000 votes in November, for the more he is 'scorched,' the 'madder' his friends get."

Brinkley ran a poor third in his race for Governor, but he came out highly successful in advertising his business.

ASTROLOGY UP TO DATE

Those doctors who think that astrology died a natural death a hundred years ago should read the obituary of Miss Evangeline Adams (Mrs. George E. Jordan, Jr.).

The *New York Herald Tribune* of November 11th says:

"Miss Adams' income from her astrological contemplations is said to have touched \$50,000 a year. She governed her entire life by astrology, even to the selection of her husband. She saw his horoscope, became interested and asked that a meeting with him be arranged. Two years later they were married, in the Little Church Around the Corner.

"She was born in Jersey City and in her infancy was taken to Andover, Mass. In her girlhood Dr. J. Heber Smith, then professor of materia medica at Boston University, selected her as a student of astrology. The mathematical talent necessary for her calculation of astrological indications, the sketch of her points out, probably was inherited from Isaac Smith, an ancestor, who made important locomotive inventions. She

studied palmistry for a while in Boston under Cheiro and opened a studio in the Hotel Copley. She came to New York in 1899."

The *Herald Tribune* gave many examples of her prophecies and said:

"She knew that neither Major General Leonard Wood nor Herbert Hoover would win the Republican nomination for President in 1920, and she told the late John W. Weeks that although he had no chance for the nomination 'he would profit greatly by the election.' President Harding appointed him Secretary of War.

"All these feats of astrology Miss Adams revealed in her book, as well as her contribution to eugenics termed 'The New Natology.'

"I have whole families of happy, healthy and lucky children who have been born on an astrological schedule," she said.

"Aquarius was a sign of success and 80 per cent of those in the Hall of Fame were Aquarius people, Miss Adams said. Pisces was a good sign for health, but the natural tendency was toward colds and abdominal disorders."

BOOK REVIEWS

INTERNATIONAL STUDIES on the Relation between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease conducted for The Milbank Memorial Fund. By SIR ARTHUR NEWSHOLME, K.C.B., M.D. Volume I. Octavo of 248 pages. Baltimore, The Williams & Wilkins Company, 1931. Cloth, \$4.00.

The medical profession must agree with the first sentence of the foreword on behalf of the Milbank Memorial Fund in presenting the first volume of the series of International Studies on the Relation between the Private and Official Practice of Medicine with Special Reference to the Prevention of Disease by Sir Arthur Newsholme—"One of the major problems in present day public health administration is that of ascertaining the proper sphere of the private physician in the field of public health."

This volume discusses the Netherlands, Scandinavia, Germany, Austria and Switzerland.

Following a general scheme which presents a preliminary summary, discusses the national or general conditions, the government's provision of medical care for the poor, hospitals and special topics such as midwifery, tuberculosis, venereal disease—and the vast amount of detail to be considered under each sub-head.

Sir Arthur succeeds in presenting the picture as he sees it in a readable way and in an interesting manner.

ALEC N. THOMSON.

THE VITAMINS. By ETHEL BROWNING, M.D. Quarto of 575 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Paper, \$10.00. (Monographs of the Pickett-Thomson Research Laboratory, Volume I.)

To quote McCarrison:—"Vitamins are but the links in the chain of essential substances requisite for the maintenance and harmonious regulation of the chemical processes in the tissues."

The Pickett-Thomson Research Laboratory of St. Paul's Hospital, London, assigned to Dr. Browning the task of compiling the heterogeneous mass of some 3,000 contributions to the knowledge of vitamins into an organized monograph. The result is an extensive work, well classified, complete, and written in a fascinating style. Part I deals with vitamins in general. The author introduces this part with an historical sketch of the discovery of the vitamins. The long line of experimentation starting with the first observations of Lunin in 1881 is accurately recounted and makes interesting reading. It represents a fitting introduction to this important book. There follow chapters on the origin of vitamins, descriptions of various theories regarding their mode of action such as the hormone theory, the chemical and physiological nature of vitamins, vitamin-mineral relationships, effects of vitamin deficiency on health and nutrition, and chapters on biological and chemical quantitative methods for estimating the vitamin content of foods. Part II is concerned with a detailed description of the chemical and physiological properties of the Fat Soluble vitamins and Part III deals equally with the Water Soluble vitamins. There follows an up-to-date and complete listing of all foods used for human consumption with a quantitative tabulation of their vitamin content.

The author has wisely condensed all this data in a final summary and conclusions in which she takes the opportunity to present a critical interpretation of contributions to this relatively new field of knowledge. The reader is thus fortunate in having the privilege of ob-

taining the expert opinions of an experienced observer on the relative merits of the many conclusions drawn from experimentation. The author closes the book with a bibliography of over 100 pages and containing some 3,000 references.

It is the feeling of the reviewer that this is one of the best books on the subject of vitamins and would prove of great value to any one interested in learning the part played by the so-called accessory food factors in the biological history of man.

WILLIAM S. COLLENS.

THE PENALTY. Must We Pay It? By DR. ABRAHAM STRACHSTEIN. 12mo of 136 pages, illustrated. New York, Good Health Publishing Co., (c.1931).

This little book is intended for the edification of laymen and ventures a synopsis of gonorrhea and syphilis from the standpoint of etiology, symptoms, course, diagnosis, treatment and prophylaxis. The advisability of such a work for general distribution may be open to question. General advice is essentially the same as contained in the literature distributed by hygiene and health societies, as well as the popularized lectures on the so-called social diseases. The author has apparently been successful in imparting fundamental scientific data in the language of the lay reader.

The introduction is devoted to a discussion of the prevalent "unwarranted attitude toward the social scourge." The author believes that regular courses on sex matters should be given in high schools and colleges, as well as public lectures in large meeting places. He advocates wide distribution of this knowledge through the national government as well as through magazines and periodicals by authoritative writers.

AUGUSTUS HARRIS.

A MANUAL OF PHARMACOLOGY. By TORALD SOLLMANN, M.D. Fourth edition. Octavo of 1,237 pages. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$7.50.

In this revision of one of the standard works on the subject some of the sections which have been re-written are those on Barbiturates, Arsphenamine fate, Cinchophen toxicosis, Gold, Liver extract, Bismuth, Mercury, Pituitary, Quinine and plasmoquin, and Sexual hormones.

As in previous editions, the main facts bearing on medical practice appear in the ordinary type and matters of less practical use are presented in smaller type. This arrangement is useful in facilitating quick reading.

It is important that this book be kept up-to-date as it is one of the mainstays of the practitioner and always a safe guide in the matters of which it treats.

W. E. MCCOLLOM.

PHYSIOLOGY OF BACTERIA. By OTTO RAHN. Octavo of 438 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc. (c. 1932). Cloth, \$6.00.

This is an advanced contribution to biology and bacteriology. As the author states, it is an attempt to co-ordinate the various simplest functions of life, to study each function itself and its effects upon the other functions. He divides his vast subject into four parts—endogenous catabolism, energy supply of the cell, growth and mechanism of death.

The work is not merely a review of the literature on the subject, it is very critical, presenting the strong and weak points of all theories, and a great many of the author's own experiments on all doubtful points.

J. COHN.

SURGICAL PATHOLOGY OF THE FEMALE GENERATIVE ORGANS. By ARTHUR E. HERTZLER, M.D. Octavo of 346 pages, illustrated. Philadelphia, J. B. Lippincott Company, (c.1932). Cloth, \$5.00. (Hertzer's Monographs on Surgical Pathology.)

This volume is profusely illustrated, mostly by the author's own specimens.

The book is very interesting reading. It is concise and to the point, and is excellent for quick reference. The author's vast experience in that branch of surgery can be used with great advantage. PHILIP OGINZ.

MENTAL NURSING (SIMPLIFIED). By O. P. NAPIER PEARN, M.R.C.S., L.R.C.P. 16mo of 304 pages, illustrated. New York, William Wood & Company, 1932. Cloth, \$2.00.

As the subtitle implies, the book is a simplified abstract of the principles of mental nursing. It is so simplified that "he who runs may read it." It is very brief, practical, and I suppose, will have a following in those who need brief reminders when dealing with mental patients. IRVING J. SANDS.

MODERN GENERAL ANESTHESIA. A Practical Handbook. By JAMES G. POE, M.D. Second edition. Octavo of 231 pages, illustrated. Philadelphia, F. A. Davis Company, 1932. Cloth, \$2.50.

The author properly calls this second edition a small volume. Its limitation to the practice of the ART accounts for this. Incidentally, one is ready to compliment him upon another limitation; and that is to write out of his own experience. So we have here another one of those smaller books which call attention to the precision of the work of the anesthetist—to those many details sometimes not regarded as important, which, however, are the very secret of ability and success. For instance, the recognition of the usual ignorance of the student whose impression of the importance of the subject has been carefully protected by the lack of instruction while at the college, and by the indifference with which the subject has been relegated in the hospital to some non-medical person. So, while the book is directly addressed to the student who has to learn the ART from the very beginning, Doctor Poe's sixteen years of experience enable him to suggest to his older fratres some matters of apparently minor interest, yet proving to be of major importance. For instance, holding the head sideways, changing the method according to the need, the description in detail of the therapeutic stage, the carefully worked-out chart of signs. The very fact that the writer has so consistently recognized the need of the student, gives his work a particular value to that ever-increasing number of surgeons whose knowledge of anesthesia is so lamentably circumscribed. In the third edition the author will add to the chapter on preparation of the patient, it is hoped, greater details in the matter of preliminary medication; none of the books cover that important subject sufficiently. A careful review of the nation of t circumstances set a atropin will be of certain value. Perhaps Doctor Poe will find it of sufficient importance to include also some description of other apparatus which is more readily procurable in other portions of the country. A discussion of the principles of their construction would certainly be at least interesting. A. F. E.

REFLEX ACTIVITY OF THE SPINAL CORD. By R. S. CREED, D. DENNY-BROWN, J. C. ECCLES, E. G. T. LIDDELL and C. S. SHERRINGTON. Octavo of 183 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$3.50.

"Reflex Activity of the Spinal Cord" possesses all of the attributes we have learned to associate with books

originating from the laboratory of C. S. Sherrington. Its purpose, to quote from the preface, is to present "a concise account of elementary features of reflex mechanism, as illustrated particularly by the mammalian spinal cord." Despite the use of the words "elementary features" by the authors, the full worth of the book probably can only be appreciated by the advanced student in neuro-physiology. In fact, the beginner, unacquainted with this subject, would quickly be lost in the maze of details presented. Starting out in an elementary vein, the contents soon become quite involved, with the result that they necessitate being read as one would a text-book. Since they are limited to a discussion of reflex in the strict sense of the word, no reference is made to the higher centers, the anatomical range extending as far as the mid-brain.

The first and second chapters deal with the structural consideration of the reflex arc, the nerve cell, the synapse and the gray matter of the spinal cord. The remainder of the contents is taken up with the physiological aspect of the matter. Such subjects as the mechanism of the flexor and stretch reflexes, inhibition, spinal "shock," occlusion and the various elements making up the latent period, which are but sparingly referred to in text-books of physiology and neuro-anatomy, are herewith discussed in detail. The phenomena of rebound, reciprocal innervation and decerebrate rigidity are also investigated. Many charts and graphs are presented in order to clarify and make the subject matter more complete. A discussion of the anatomical features of muscle receptors in mammals, together with plates illustrating the various types, is especially interesting and instructive. The bibliography, although not voluminous, appears to be quite complete in its scope. DAVID I. ABRAMSON.

RECENT ADVANCES IN PATHOLOGY. By GEOFFREY HADFIELD, M.D., F.R.C.P., and LAWRENCE P. GARROD, M.A., M.B., B.Ch., M.R.C.P. Octavo of 390 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, 1932. Cloth, \$3.50.

In this volume the authors present a résumé of the latest investigations in a number of important or interesting disease processes. New discoveries in pathology and allied sciences are constantly changing our conception of disease. This volume provides much new knowledge in a very readable form. One does not have to be a pathologist to read it.

There is a full discussion of the functions of the reticulo-endothelial system, the latest in cancer research and chapters on cardio-vascular disease, pneumonia and the pneumoconioses. The discussions of necrosis of the liver and Bright's disease give the latest thought on these subjects and should clarify one's ideas about them. The chapter on the encephalitis problem is excellent and timely, with a simple, workable classification. In the concluding chapters, the authors present the latest findings in parathyroid and adrenal physiology and pathology. The illustrations are numerous and good and there are many references to the newest literature for more detailed study. E. B. SMITH.

THE EXPECTANT MOTHER'S HANDBOOK. By FREDERICK C. IRVING, M.D. 16mo of 199 pages, illustrated. New York, Houghton Mifflin Co., 1932. Cloth, \$1.75.

A handbook for mothers by the Professor of Obstetrics at Harvard. It goes rather deeply into the anatomy and physiology of reproduction, and the biological aspects of pregnancy, and is written apparently for the benefit of the patient with somewhat more than average intelligence and education. The general hygiene of pregnancy is well handled. Not much space is devoted to the baby itself, but many questions which arise in the patient's mind are adequately answered. Of handy size, and well printed, it is a good book for the type of patient who has an intelligent interest in her condition. CHARLES A. GORDON.

OUR NEIGHBORS

CONTRACT PRACTICE IN TEXAS

The expulsion of a number of members of the Medical Society of the County of Dallas, Texas, on the ground of doing contract practice was noted in this Journal of August 1, 1932, page 936. *The Texas State Journal of Medicine* for November, 1932, has a three-page editorial on the case. The expulsion by the County Society was upheld by the State Medical Association, but with the provision that the members be reinstated immediately on their abandonment of the objectionable contracts.

The State Association appealed to the American Medical Association, which sustained the decisions of the Texas State Association and the Dallas County Society.

The editorial in the November issue of the Texas State Journal explains the grounds of the decisions as follows:

"Prosecution in this case was based primarily upon Section 2, Article VI, of the Principles of Medical Ethics of the American Medical Association. This section reads as follows:

"It is unprofessional for a physician to dispose of his services under conditions that make it impossible to render adequate service to his patient or which interfere with reasonable competition among the physicians of a community. To do this is detrimental to the public and to the individual physician, and lowers the dignity of the profession."

"This amendment was approved by the board of councilors, but it is of interest to note that the board of councilors in rendering its decision based the same on the provision of the Principles of Medical Ethics involved, declaring the by-law out of order because not necessary.

"The Judicial Council of the American Medical Association, in its effort to interpret the above section of the Principles of Ethics, some time ago published five basic points of consideration in connection with contract practice. We quote these:

"1st. When the compensation received is inadequate, based on the usual fees paid for the same kind of service by the doctors in the same community.

"2nd. When the compensation is so low as to make it impossible for competent service to be rendered.

"3rd. When there is competitive bidding in order to secure the contract.

"4th. When a free choice of physicians is denied.

"5th. Solicitation of patients, directly or indirectly."

"The contract believed to be of less ill-effect was as follows:

"Upon the payment of \$200.00 per month, the services of your staff are available to the officers and employees of this bank for consultation, examination and treatment of minor cases of illness in our building when necessary. However, employees are not required to accept this service, but are free to employ the services of their family physician at their expense if they so desire.

"Any treatments given our employees at the clinic and all home visits are made at the request of the employee, without any knowledge or liability on the part of this bank, and we presume the charges made in such instance are in accordance with the economic standing of such employee."

"The other contract was as follows:

"For the consideration herein stated, the clinic agrees to render all necessary surgical and medical treatment for members of the Association, such members to be composed of white employees, male and female, of the Dallas Railway Company and Texas Interurban Railway, through physicians connected with the Dallas Medical & Surgical Clinic, the Clinic agreeing to appoint a competent person, graduate in medicine and surgery as Chief Physician and the Clinic agreeing to furnish consultation service and active assistance when necessary so as to fully cooperate in the performance of the services herein contemplated."

The contract continues in considerable detail regarding offices, x-ray, and other details:

"The decision of the Judicial Council of the American Medical Association, which is final so far as our own tribunals are concerned, is as follows:

"The fundamental issue in dispute in this case is the ethical character of certain contracts held by the appellants to give medical service to groups of people on a monthly per capita plan of payment. No essential facts of the contracts were in dispute.

"It is contended by the appellants that these contracts are not in violation of all or any of five conditions which the Judicial Council has declared at various times are conditions, which obtaining, make a contract unethical. The Dallas County Medical Society which sentenced these appellants to suspension contended that these contracts violated all five of these conditions. When, in its constitutional function as authority over ethical matters, the Judicial Council expounds the

PERSISTENT, AGONIZING NEURAL PAINS RELIEVED!

In a series of cases of obstinate, agonizing distress resulting from neural pain, definite relief was obtained from the following basic treatment, as outlined by Dr. M. D. Bloomfield in American Medicine, September, 1932.

Plan of Procedure Followed:

1. Removal of all suspected and visible foci of infection;
2. Physiotherapy in the form of diathermy, heliotherapy, irradiation therapy, and hydrotherapy;
3. Dietetic measures instituted toward corrective assimilation and metabolism;
4. Magnesium sulfate for its eliminative hepatic and detoxicating effect;
5. Mono-Iodo-Cinchophen for the absorptive and alterative effect of the nascent iodine and the analgesic and sedative action of the cinchophen.

Mono-Iodo-Cinchophen is available for clinical use under the name Farastan. This is the same product which has proved so effective in the alleviation of pain, reduction of swelling, and increase of motion in arthritic and rheumatoid conditions.

(Continued from page 1392)

subject of contract practice and lays down certain principles which, when present, create an unethical contract, it is not to be assumed that those are the only principles which may have that effect. A fundamental of medical ethics is that anything which in effect is opposed to the ultimate good of the people at large is against sound public policy and therefore unethical. On the five points mentioned the appellants presented a strong argument which might be convincing if a narrow or local view only is considered. Nevertheless the Judicial Council is of the unanimous opinion that this type of contract is unethical on the basis of being contrary to sound public policy.

"The appellants were at the same time convicted of violation of a by-law of the society forbidding the holding of certain contracts and pleaded error in the trial on a technical procedure. This phase of the appeal was not pressed by either side, but from such records as were submitted to the Council it is of the opinion that no reversible error was proven.

"The action of the Board of Councilors of the State Medical Association of Texas is confirmed."

The concluding comment of the editor of the Texas Journal is as follows:

"It was not charged in the Dallas case, we believe, that there was any direct solicitation of patients by the group involved, but it was not clear, and the facts were not presented in the pleading, that those responsible for the organization of the group to be served did not solicit members. Certainly that would be an element that could not be very well controlled by the medical profession, and most doctors have every reason to be leery of high-pressure salesmen. We are convinced that this phase of the situation is of extreme importance. No matter how we safeguard any plan looking to the insurance of our people in the matter of health and sickness and incidental medical service, there is always the thought to be considered and the possibility, may certainly, that financial consideration will eventually prevail, and control will pass to those not so considerate of medical ethics and public policy."

ADMINISTRATIVE FUNCTIONS OF STATE SOCIETY OF IOWA

An editorial in the October Journal of the Iowa State Society discusses the administrative functions of the Society, as follows:

"It is the central office, through which flow all currents of Society policy and activity, guided, directed and unified by the Society officer. Each officer, department and committee fills a particular role in the scheme, some advisory, others more specifically administrative. In the House of Dele-

gates each year are determined the policies which shall shape the Society for a twelve months' period, and it becomes the responsibility of the officers to interpret and enact these policies.

“The commodity which the physician offers for sale cannot be measured by the yardstick, pound or liquid measure. Nor can its quality or amount be ordered by the customer. As merchant of his wares, it is the physician's peculiar province to determine the needs of the customer. This determination, multiplied to the needs of a population, becomes tangibly involved in the economic and political problems of a state. The medical profession, willingly or not, finds itself imbued with the responsibility of gaining by legislation enactment of those measures which it deems necessary to the health of the public. Thus, through its Committee on Public Policy and Legislation, is directed the legislative function of the state society. By cooperation with the Department of Health, through the Law Enforcement Division, the health laws of the state are enforced.

“That health legislation should have its origin and leadership in the medical profession is self-evident. For some time, popular lay journals have been furnishing much material to further excite our already health-sensitive public, with the result that numerous lay organizations have sprung up, like mushrooms, to direct the interests of the public in health matters. These activities should have the direction and guidance of the medical profession.”

A second administrative function of the State Society is directed cooperation with the various state and local lay health agencies. Here, again, the activities of these agencies should be supervised by the medical profession. This fact was recognized in the Forty-third General Assembly by the passage of the permissive county health unit law. A united county medical society, the unit of organized medicine, has the qualifications, the willingness, the interest in its own citizenry, to promote and execute the health activities of the county. Where state or federal subsidy is needed, the request for such subsidy will win its merited consideration if coming from the medical profession.

“The correlation of the activities of the various county societies is a third administrative function of the Society. In the strength of the integral units, the component county societies, lies the strength of the parent organization. The State Society is directed by the policies of these units, but upon the wise guidance of these policies and the furtherance of fraternity, depends the effectiveness of their combined purpose. Certain agencies of the State Society render specific assistance to the individual members, such as medico-legal defense and protection. The Medical Economics Committee has been effective in ad-

vising the members as to the fallacy of schemes offering pseudo-ethical collection services, and participation in various professional listings of doubtful value to the physician. These are sub-heads under the general classification of 'service' to the members of the organization, but their numbers and types are numerous. They represent, as a group, one of the more concrete aspects of the administrative function of the Society.

"Prosaically entangled in the execution of all activities of the Society is the administration of its fiscal affairs. The very momentum of Society enthusiasm, doubling and trebling the activities and expenses, places a heavy burden on the Society's dollars. A judicious budgeting of these dollars, and an occasional forceful tightening of the purse-strings is by no means the least of the administrative functions."

JOURNAL IN PENNSYLVANIA

The editor of the *Pennsylvania Medical Journal* describes the several departments of the Journal in the October issue, and says:

"The Journal is the house organ of our State

Medical Society, and is delivered to you every month. It brings to you a wealth of material and information, and keeps you regularly advised of the advancements in the art and science of medicine, and the activities of organized medicine, within and without the State.

"The members must read their State Journal to know why cooperation is essential, and how they can best do so. Unless we solve our own problems, working as a unit with our State Officers, the laity will solve them for us, much to our humiliation, embarrassment, and detriment. Hence the need for 100 per cent concerted action.

"The 'Table of Contents,' the Publication Committee and editorial personnel, and other matters pertaining to the business of the Journal, are always to be found on page v of the advertisement section. On and after October 1, 1932, authors submitting voluntary contributions will be required to inclose postage for return of the article, should it not be accepted for publication. A voluntary contribution is an article that has no relationship with the official transactions.

"The Transactions must be published within one year from the Annual Session of the State Society, and require eleven numbers of the Journal. This affords the acceptance of a limited number of voluntary contributions each year, and they are all published at one time in the October number.

"The Officers of the State Society, the Chairmen of Committees, and the Section Officers are always to be found on page vi of the advertisement section.

"The Officers, and Committee Chairmen of the Woman's Auxiliary to the A.M.A., are always to be found on page viii of the advertisement section.

"**EDITORIALS:** These columns are used to convey editorial thoughts upon subject matter that is expected to be of more than passing interest to the reader. Any member editorially inclined is cordially invited to contribute to these columns, subject to approval by the Editor. The various committees and commissions could use the editorial columns to distinct advantage, as has been so ably demonstrated by the editorials submitted by the Committee on Mental Hygiene for monthly publication, during the past few years."

The editor also discusses the other departments of the Journal including the following:

- Original articles
- Comments and excerpts
- Hospital activities
- Public health
- Physical therapy
- Industrial medicine
- Tuberculosis abstracts
- Officers Department
- Medical legal notes
- County Society Reports
- Deaths, marriages, births, etc.
- Book reviews
- Advertisements.

The Pennsylvania Journal is comprehensive in its scope, and its varied items make a strong personal appeal to the members of the county societies.

ADVERTISING CHARGES IN COLORADO JOURNAL

The September number of *Colorado Medicine* discusses a complaint that the costs of advertising a medical ware greatly increase the cost of the product to the customer. The editorial says:

"Occasionally a doctor criticizes manufacturers or dealers for their advertising expenditures, in the belief that products could be sold more

(Continued on page 1399—adv. xix)

(Continued from page 1398—adv. xviii)

cheaply if advertising costs did not have to be figured into the price of each product. Happily these objectors are few; but there may be others who think the same way without having ever put their thoughts in writing, and for them this is written.

"Whenever a manufacturer trims his costs he increases his profits, or reduces his prices, or does both. No manufacturer is in business 'for his health,' so when the most firmly entrenched companies spend increasing amounts to keep their products advertised before the medical profession, no other proof of the economy of such advertising should be needed."

The editor then prints a letter from a prominent national advertiser which says:

"Your state medical journal requires 1,700 copies of our colored insert, which cost approximately \$13.50. The carrying charge for this in one issue of the journal is \$45.00, making a total cost of \$58.50. This makes the insert that goes to each physician cost 3.4 cents. It always represents two products or two groups of products.

"From this it can be seen that if we should make an allowance in the price of the product equivalent to the cost of advertising, the fraction of saving to any one patient or to the total amount of the items prescribed by any one physician would be so small that it could not be represented in any of the terms of our U. S. coins.

"Another point that is particularly important is that the greatest possibilities of price reductions come through economies resulting from increased production in response to a demand which advertising helps to create.

"In the case of the colored inserts, practically three-fourths of the amount expended by the manufacturer goes to the journals that carry the advertising; and of the advertising on black and white pages, practically all of it is paid to the medical journal. If it were not for the advertising undoubtedly most of the state medical journals could not be maintained except at a heavy cost to the state societies, which would necessitate charging a very high subscription rate, one that would work a hardship on many physicians. The same is true of other medical journals, so that after all the amount the advertiser pays out rebounds directly to the benefit of the physician."

FULL-TIME SECRETARY IN KANSAS

The August issue of the Journal of the Kansas Medical Society records the following action regarding the employment of a full-time lay secretary:

"At the annual meeting last spring, a resolution was presented empowering the Council 'to arrange for the reorganization of this Society and

to provide for the employment of a full-time lay executive secretary.

"The plan as proposed was not in any way a reflection on the ability or the work of the officers of the Society. Naturally, the officer of any organization who is employed full-time, devotes his entire time to the work of the organization he represents. Consequently, a full-time secretary would give his entire time in the interest of the organized medical profession.

"According to information available in the Journal office, fourteen state medical societies employ a full-time secretary. Eight of these, namely, Colorado, Georgia, Indiana, Iowa, Maryland, Ohio, Oregon, West Virginia and Wisconsin employ a lay secretary. California, Maine, Massachusetts, Minnesota, Missouri, New Jersey and Texas employ a full-time secretary who is a doctor of medicine. The salaries received by lay secretaries vary from \$3,600 to \$8,000, with an average of \$5,770; the minimum salary of the

medical secretary is reported as \$3,000, maximum \$7,245, the average being \$4,620.

"The full-time secretary, if employed, in reality would be the business manager of the Society. The Council and regular committee would lose none of their power, and undoubtedly would be more active in society affairs. It is not believed the full-time secretary could arrange more attractive programs for the annual meeting, but probably could stimulate the attendance, for he would make personal contact with all of the component societies at their regular meetings. Prior to the meeting of the legislature, he could make a tour of the state, become personally acquainted with each member of the House and Senate and present for their consideration the attitude of scientific medicine. It would be possible for him to be in daily and constant attendance at the legislative sessions and, through the legislative committee, keep the members advised as to contemplated medical legislation. He would, in addition, have many other duties."

DOCTORS IN THE PRIMARIES OF CALIFORNIA

The October issue of *California and Western Medicine* contains the following editorial describing the part taken by the doctors of Los Angeles in the primary elections:

"In the recent primary election the Los Angeles County Medical Association showed how the medical profession may make its influence felt in the selection of candidates to the legislature and other state offices.

"The officers of the Association made an accurate survey of each of the thirty assembly districts of Los Angeles County, and then appointed special subcommittees or key-men for each of the assembly districts, sending special letters of information to all members in each district so that contacts with the key-men were made easy. In a preliminary announcement in the Bulletin of the Los Angeles County Medical Association, printed on August 18, Secretary Harry Wilson stated:

"The association is interested, as any group of intelligent and patriotic citizens should be, in good government. The Association urges its members to support only those candidates who stand for good, constructive government. It asks its members to learn more about the candidates in their districts than they have been accustomed to learning in the past, and for a very definite reason.

"The Association feels that good government is sufficient for the protection of the medical profession. It asks its members not only to vote intelligently, but to aid in the cam-

paigns of such candidates they as individuals, select as worthy.

"After the primary election it was possible to estimate somewhat the effectiveness of the work which had been done, and it was most gratifying to note that the end-results fully warranted all the efforts that had been put forth. If the largest county medical unit of the California Medical Association was able to do these things in a metropolitan community, where political forces are many and difficult to overcome, then other county units should be able to get results equally efficient. The open letter which Dr. William R. Molony, president of the Los Angeles County Medical Association, submitted to the Los Angeles County Medical Association after the primary election, was printed in the September 15 bulletin and is as follows:

"Politically minded! Our critics have been saying so—these many years, that we have lacked this quality. But no more—at least for this year—can we be accused of being careless and asleep at the switch. The enthusiastic cooperation of the members of our Association during the recent primary campaign was most gratifying and is a source of added zest to the members and officers of the Los Angeles County Medical Association.

"The major credit must go to the group of earnest men who comprised the executive division of the Legislative Committee and who in turn were the 'key-men' in their respective assembly districts. In practically every district the nominees of both the Republican party and the Democratic party were men and women endorsed by the Los Angeles County Medical Association as candidates worthy of our support for good government, education, and public health.

"The Los Angeles County Medical Association has a membership of more than 2,100. Your influence is more widespread and penetrating than any other similar group in the county, and if you do not fully capitalize this asset it is in a sense your own fault. We should not exert our power for selfish purposes, but rather for good government, proper medical standards, and for the public health."

MEDICAL LEADERSHIP IN OREGON

The July number of *Northwest Medicine* has an illuminating editorial on medical leadership, which says:

"Dr. Nicholas Murray Butler has recently given a clever division of the people, or the nations of the earth, into three classes. He said: 'There are

a few who make things happen, the many more who watch things happen, and the overwhelming majority who have no notion of what happens.' Everyone is born into the third, and by far the largest group. Advance to the second group comes through effort and education. As the sum total of concepts and experiences increases, interest and curiosity become aroused and we make opportunities to 'watch things happen'. The first and smallest group are those 'who make things happen'. This group has all of the attributes of the second group, plus initiative and action.

"A survey of the membership of our medical societies on the basis of the above classification may stimulate ways and means of developing medical leadership from group two and an enlightened support from group three. The most efficient way to eliminate group three from our medical society membership is to encourage service on some committee activity where one will contact members of the other two groups. To hear the problems of the profession discussed in small groups where thought-provoking plans are submitted cannot help but stimulate thought and interest. When interest is aroused, action soon follows. With the problems of state medicine, contract medicine and group medicine before the medical profession, we cannot afford to permit many members to remain in group three. The more enlightened the county and state medical society membership becomes with regard to the above problems of future medical practice, the sooner we will develop an intelligent leadership capable of formulating policies and practical solu-

tions to these problems which will be worthy of intelligent and cooperative support."

MEDICAL AIMS IN MICHIGAN

The October issue of the *Journal of the Michigan State Medical Society* prints an editorial in which it enumerates the following ten ideals of the editor:

"1. Reports of every county meeting and what your local society is accomplishing. Reports should be in the State Secretary's hands not later than the fifteenth of each month.

"2. News items of general interest.

"3. Patronage of our advertisers. Give them your business in preference to non-advertisers.

"4. Subscribers to our Medical History—two volumes at \$7.50 per set. They are a splendid and appreciated gift to friends, hospitals and libraries.

"5. A resolve to participate actively in the work of your county society, and to accept and discharge committee duties.

"6. The extending of an invitation to every eligible doctor, urging him to affiliate.

"7. Not knowingly or unknowingly to be the cause for a damage suit against a fellow physician by ill-advised remarks or comments.

"8. Cooperation with your local health officers.

"9. Advising your patients to permit your vaccinating and immunizing their children and to do it yourself at a reasonable fee.

"10. Calling consultation and assistance in all serious cases and those in whom the diagnosis is undetermined."

THE DR. C. O. SAHLER SANITARIUM

Pleasantly located in the suburbs of the charming city of Kingston. Within easy access of New York, and with all modern facilities for treatment of selected cases of Organic and Functional Disorders of the nervous system and invalidism from any cause. Average price of rooms—without bath—\$5.00 per day including ordinary medical and nursing attention. No cases of insanity or communicable diseases accepted. Booklet on request. Telephone Kingston 948. Raymond S. Crispell, M. D., Medical Director.
Kingston-on-Hudson, New York

COLUMBIA UNIVERSITY NEW YORK POST-GRADUATE MEDICAL SCHOOL

offers a course of six months' duration in

UROLOGY

beginning January 3, 1933

Under the direction of Dr. Joseph F. McCarthy. The course approximates 34 hours a week, and includes: Demonstrations of urologic operations and diagnostic procedures; cystoscopy and endoscopy; operative urologic surgery on the cadaver; urographic studies and interpretation; pathology, bacteriology, and biochemistry of genito-urinary diseases; newer methods of endoscopic revision of prostatic hypertrophy, etc. The class is limited to ten. The seminar is a full-time six months' course and part-time work will not be permitted. For further information, address

THE DIRECTOR,

302 EAST 20th STREET, NEW YORK CITY

TEACHING ECONOMICS TO INTERNS IN WISCONSIN

The instruction of internes in medical economics is described in the July issue of the *Ohio State Medical Journal*, as follows:

"A plan recently inaugurated by the Educational Committee of the Medical Society of Milwaukee County, Wisconsin, of holding conferences for hospital interns, the purpose of which is to discuss some of the practical social and economic problems which confront the young physician just entering practice, suggests similar activities on the part of other medical groups located in centers having hospitals where intern training is given.

"Commenting on the activities of the Milwaukee committee along this line, the *Milwaukee Medical Times*, official publication of the society, said editorially:

"Unfortunately many young physicians do not realize the importance of some business training until they are out of practice. They are then too busy to give this side of their practice much attention, which often results in deplorable situations. A review of the estates left by physicians is an eloquent reminder of this, fact. It is obvious that if all medical schools would include in their curricula a short course in medical economics and simple business methods, this condition in which physicians too often find themselves, would be greatly improved. The Educational Committee has come to the conclusion that it can do something to meet this situation."

"Many county medical societies or academies of medicine in Ohio would be in a position to add some such activity to their programs."

PRESS PUBLICITY IN SOUTH CAROLINA

The September issue of the *Journal of the South Carolina Medical Association* contains the following editorial on press publicity:

"For the first time the South

**Diuresis is recommended
in many forms of
Heart Disease
as an adjunct to other
appropriate treatment.**

Poland Water

**may be relied upon
to induce diuresis
without any
untoward effects.**

For Information

**POLAND SPRING
COMPANY**

Dept. C

680 Fifth Avenue
New York

Carolina Medical Association enters upon a publicity program through the newspapers of the State on preventive medicine measures to be carried out by the layman. These articles are being sent out to both the religious and secular press at frequent intervals. The first one was on appendicitis, the second one on the prevention of diphtheria. These contributions have been presented by members of the association on invitation from the Committee on Public Health of the State Medical Association of which Dr. R. M. Pollitzer of Greenville is the Chairman. The copy is prepared and sent out from the headquarters office of the State Association. None of the articles are signed. There has been a splendid response on the part of the press in the publication of these articles. It is entirely a service in the interest of the people of South Carolina."

LENGTH OF ARTICLES IN NEBRASKA JOURNAL

The following editorial in the October issue of the *Nebraska State Medical Journal* will apply to New York as well as Nebraska:

"A contemporary (*Mich. Med. J.*) reminds its readers that medical papers should be brief because there are very few medical journals which can accommodate the lengthy paper. This reminds us to state to our contributors that we have more lengthy papers on hand than ever before. The only thing to do is to cut them into two or three parts for publication. This is not desirable, but necessary. We have a number of times reminded our readers that the short, snappy paper is the one that is read. The lengthy paper tires the reader. Medical journals are picked up by physicians at odd moments and the short, crisp items are read while the lengthy article gets little but a glimpse at the title. No independent medical journalist would accept and publish the long drawn-out papers a state journal must perforce publish. If you wish to reach the reader 'make it short and snappy.'"

CLASSIFIED ADVERTISEMENTS

Classified ads are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1.50; three cents each for additional words.

Exceptional opportunity for doctor to establish in a thriving community, East New York-Brooklyn. Practice waiting. For Rent—7 rooms suite corner, formerly occupied by doctor. Inquire Evan's Pharmacy, 192 Montauk Avenue, Brooklyn. Phone Applegate 7-9581.

POSITION WANTED—Refined, educated, young woman, seeks part time position, in physician's office. Capable—tactful—pleasing telephone voice. Or would act as part time companion, secretary, to physician's patient. Interview welcomed. Phone Academy 2-7895.

NEW INSULIN PUBLICATIONS

There is a growing recognition of the therapeutic significance of adequate carbohydrate utilization, glycogen storage, and related metabolic processes. Since these fundamental mechanisms are so susceptible to therapeutic manipulation it is quite certain that literature on the dietetic management and use of Insulin, and the use of Insulin in non-diabetic malnutrition will prove of interest to many physicians.

From the press of Eli Lilly and Company there recently appeared two publications which have to do with the far-reaching physiologic and pathologic phenomena of carbohydrate metabolism.

The first booklet is entitled "Diabetes Mellitus—A Method of Dietetic Management and the Use of Insulin." The second bears the title, "The Use of Insulin in Non-Diabetic Malnutrition."

The first is a monograph, precise, clear, dependable, in which special effort has been made to simplify dietetic problems. The second is a condensed review of the literature on the use of Insulin in malnutrition dependent on various causes. Specific indications are mentioned together with details of dosage in infants, children, and adults. Both pamphlets are available without cost to physicians. Address Eli Lilly and Company, Indianapolis, Indiana. See page xii.—*Adv.*

ANNOUNCEMENT

The formal opening of the Chinese Lounge, atop the main building of the New York Polyclinic Medical School and Hospital, took place on Thursday, November 10th, at 3 o'clock, with the Honorable John P. O'Brien, Mayor-elect of the City of New York, and the Honorable Henry K. Chang, Chinese Consul-General, officiating. This Chinese Lounge is for convalescent patients. The opening was attended by a large gathering. Refreshments were served. See page iv.—*Adv.*

WARNS AGAINST PROMISCUOUS DOSING WITH VITAMINS

Ever since 1914, when S.M.A. was developed, the producers of S.M.A. have been interested in proper appreciation and application of the vitamins, particularly A and D.

Vitamin research has been carried on without fanfare by S.M.A. Corporation since its formation in 1921. As a result, when the fad for irradiated products swept the medical world, the research chemists of S.M.A. Corporation were not satisfied with an artificial source of Vitamin D, and reserved judgment, continuing to use the old, reliable cod liver oil in S.M.A. and to remind the medical profession of this fact. (S.M.A. and Smaco products are not advertised to the public.)

As another result of this research, S.M.A. Corporation was recently able to announce the availability of Primary Vitamin A (Carotene) for therapeutic use at moderate prices.

This is not only a boon to physicians in making possible the prescribing of Vitamin A alone, as well as Carotene for its own virtues, but it will also make possible further research on the properties of Vitamin A. Such an important announcement could not long remain a secret from the press of the country, and about two weeks after the announcement to the medical profession, an interview was printed in which W. O. Frohring, Vice President and Director of Laboratories, was quoted as follows:

"We are offering carotene to the medical profession in three convenient forms,—Crystalline carotene for research purposes; Caritol, which is carotene in bland oil, and cod liver oil with carotene.

"While it is confidently expected that these products will prove to be of immense value to the public, they are not intended for use by the public except under the direction of a physician."—See page ix.—*Adv.*

VITAMIN "D"

Winter is a jailer who shuts us all in from the fullest vitamin D value of sunlight. The baby becomes virtually a prisoner, in several senses: First of all, meteorologic observations prove that winter sunshine in most sections of the country averages 10 to 50 per cent less than summer sunshine. Secondly, the quality of the available sunshine is inferior due to the greater distance of the sun from the earth altering the angle of the sun's rays. Again, the hour of the day has an important bearing: At 8:30 A. M. there is an average loss of over 31%, and at 3:30 P. M., over 21%.

While neither Mead's Viosterol in Oil 250 D nor Mead's 10 D Cod Liver Oil with Viosterol constitutes a sub-

stitute for sunshine, they do offer an effective, controllable supplement especially important because the only natural foodstuff that contains appreciable quantities of vitamin D is egg-yolk. Unlike winter sunshine, the vitamin D value of Mead's antirachitic products does not vary from day to day or from hour to hour. See page xxviii.—*Adv.*

PAIN!

For the treatment of pain and stiffness accompanying rheumatic and other disorders in the extremities, the application of heat is the most useful single measure known.

The local application of heat has a pronounced effect upon the circulation of the blood and lymph. It results in the relaxation of tissues, in improved metabolism and in helping to carry away the various exudates, inflammatory products and bacterial poisons deposited in the diseased joints and inflamed nerve sheaths.

Experience has demonstrated that there is no more effective application for dilating the superficial and deep vessels than through the use of Antiphlogistine. Its heat-retaining qualities, coupled with its high glycerine content and other components, produce an intensive hyperemia and causes the blood to flow in larger quantities from the deeper tissues to the surface under treatment. Thus, through the dilatation of the blood-vessels and the locally increased osmotic exchange, the pathological products are poured in larger quantities into the blood and there destroyed.

For the pain, stiffness or swelling associated with arthritis in the wrists, ankles, hands or feet; for sprains and strains; in fibrositis of the palmar or plantar fascia in the manipulative treatment of flat foot, where muscular relaxation is desired, the use of Antiphlogistine is always indicated. Physicians are invited to write to the Denver Chemical Mfg. Co., 163 Varick Street, New York, for sample and literature. See page ii.—*Adv.*

ERYSIPELAS

The recent reports by Symmers and Lewis of Bellevue Hospital covering the results following the employment of Erysipelas Antitoxin are most gratifying. These results are based upon the treatment of three thousand three hundred cases.

The season when erysipelas causes disability is close at hand, and physicians should be acquainted with this development and the results following the use of the product of the LEDERLE LABORATORIES.

Full information will gladly be supplied by communicating with them at 511 Fifth Avenue, New York City. See page vii.—*Adv.*

SOME CLINICAL FEATURES OF DEFICIENCY DISORDERS

By CHESTER S. KEEFER, M.D., BOSTON, MASS.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and Department of Medicine, Harvard Medical School
Read before the Academy of Medicine, Rochester, N. Y., April 7, 1932.

Introduction

THE food deficiency disorders have for many years received study by those who have investigated the problems of nutrition, but only in recent years have they attracted the general attention of clinicians. As information accumulates regarding these conditions, it becomes clear that the tissue changes which result are extremely varied and widespread. This state of affairs naturally leads to a great variety of clinical symptoms and signs. In order to recognize these conditions, it is important that we have some understanding of the circumstances under which food deficiency disorders occur and the changes that follow.

It is now clear that food deficiencies may arise, not only as a result of inadequate diets, but they may occur as a complication of processes which interfere with normal nutrition such as a chronic diarrhoea or when added demands are made on the body, as in pregnancy. Finally, it is now known that a deficiency disorder may arise as the result of the failure on the part of the body to manufacture certain essential substances. The example of this type of deficiency is pernicious anemia, which develops, in most instances at least, as a result of a defect in the stomach which interferes with the manufacture of a factor which is necessary for normal hematopoiesis.

If we remember then, that deficiency diseases can and do occur under the circumstances mentioned, we can appreciate the great variety of conditions under which they may be observed.

There are two other factors which must be borne in mind in order that the clinical picture may be interpreted accurately, first, that dietary deficiencies in man are usually multiple and not single, and secondly, that the tissue changes, which occur as a result of deficiency, are so often the site of infection that the fundamental tissue changes due to the deficiencies themselves may be overlooked.

That deficiency disorders in man are usually multiple is not surprising, because single deficiencies may be studied in animals only after the diet has been planned with meticulous care. The

diet of man is never so arranged and is dictated largely by such factors as geographical location, class custom, habits, race, and the general economic status. It is only natural then that diets which are deficient in one way are usually deficient in others. This is supported by numerous clinical observations.

The relation between food deficiency and infection is not thoroughly understood, but the two are commonly associated under circumstances that make one feel that tissue changes resulting from the deficiency disorders predispose to infection. This question has received most attention in connection with vitamin A deficiency. The conditions in which the various deficiency disorders occur are summarized in Table I.

Vitamin A Deficiency: It has been customary in discussing vitamin A deficiency to consider

xerophthalmia or keratomalacia as the characteristic lesion resulting from this defect. It is now recognized that these conditions may not occur until other manifestations of the deficiency have been present for considerable periods of time. The investigations of Wolbach and Howe¹ and others² have conclusively shown that the characteristic changes of vitamin A deficiency occur in the epithelial tissues. There is a widespread keratinization and replacement of the epithelia by stratified keratinizing epithelium in various parts of the respiratory and alimentary tract, in the eyes, paracocular and salivary glands and in the genitourinary tract. The changes in the various organs result in symptoms or allow infection to take place. In Table II the organs in which changes occur together with their clinical features are summarized.

TABLE II
VITAMIN A DEFICIENCY

<i>Pathologic Lesions</i>	<i>Clinical Manifestations</i>
Keratinization of Epithelial Tissues	Night Blindness
Conjunctivæ	Xerosis Conjunctivæ
Cornea	{ Xerosis Cornæ Keratomalacia
Lachrymal Glands	Diminution Tear Secretion
Parotid Glands	Xerostomia
Mouth	{ Xerostomia Leukoplakia
Trachea and Bronchi	{ Bronchitis—Tracheitis Bronchiectasis—Pneumonia
Intestine	Ulcerative Colitis
Genito-Urinary Tract	{ Cystitis Urolithiasis
Skin	Hyperkeratosis Follicularis

The main ocular symptoms in vitamin A deficiency have been recently discussed and summarized by Pillat.³ Night blindness is an inability of the patient to see at twilight, especially after sunset. The diagnosis is made from the history, because there are no characteristic findings on physical examination, the ocular fundi being normal in appearance. It may occur without any other ocular symptoms or it may be associated with xerophthalmia or keratomalacia. The natural history of the development of these lesions is as follows: the first feature is a dryness of the bulbar conjunctiva with a loss of lustre. In the beginning the areas of dryness occur in small patches near the limbus extending toward the lid angle, then they spread in other parts of the conjunctivæ. The sensibility of the conjunctivæ is reduced and finally there is some wrinkling of the conjunctivæ. The process then progresses to the

cornea and produces dryness, a great increase in the number of epithelial cells and numerous bacteria may be observed in scrapings from these areas. Finally if the process is allowed to progress, softening of the cornea with corneal ulcers occur, which may penetrate the anterior chamber and cause blindness.

The lesions in the respiratory tract consist of desquamation of large numbers of epithelial cells with a replacement by keratinized epithelium. This may lead to the development of localized areas of bronchopneumonia and bronchiectasis.

In the genito-urinary tract one finds changes in the epithelium, giving the appearance of leukoplakia. The urine may contain large numbers of epithelial cells and infection and calculi are common. It would appear as if the altered epithelium allows infection to take place much more readily than when normal epithelium is present.

The alterations in the epithelial tissues of the gastrointestinal tract are similar to those described elsewhere and may lead to ulceration and subsequent diarrhoea. It is common to have diarrhoea in patients with vitamin A defects and it promptly disappears following adequate treatment.

Hyperkeratosis Follicularis: This condition of the skin has recently been studied most carefully by Frazier and Hu.⁴ They pointed out that the essential changes in the skin were similar to those observed in experimentally controlled cases of vitamin A deficiency, and since many of their cases were observed in patients with the characteristic lesions of vitamin A deficiency, there seemed to be little doubt as to the cause of these lesions.

They described the natural history of the development of the skin lesions somewhat as follows: At first the skin becomes dry and slightly rough—then spinous papules appear at the sites of the hair follicles, and involve the antero-lateral aspect of the thighs and the postero-lateral aspect of the forearms. These lesions gradually spread to the extensor surface of both upper and lower extremities, the shoulders, and the lower part of the abdomen and to a less extent to the chest, back, and buttocks.

Histologic examination of these cutaneous lesions showed the pathologic process to be one of hyperplasia and hyperkeratinization of the epithelium of the epidermis and hair follicles, with associated metaplasia of the epithelium of many of the sweat ducts to the keratinizing type, degeneration of the glandular structures of the skin and infection.

Striking improvement in the condition of the skin followed the ingestion of cod liver oil. The cutaneous lesions gradually disappeared, leaving delicate atrophic scars surrounded by a zone of brownish pigmentation at the follicular orifices. Over two months may be required for the skin to regain its normal appearance.

Other conditions, such as xerostomia, may result from changes in the parotid glands due to lack of vitamin A. Changes in the lachrymal glands with diminished or absent lachrymation as a result of vitamin A deficiency are also recognized. In reporting a case of xerostomia and lack of tear secretion, Chamberlin⁵ suggested that the changes producing the clinical picture were probably due to a deficiency disorder.

Vitamin B Deficiency: Due to the fact that vitamin B is a complex substance, and that its lack may result in a variety of changes, it is difficult to define with precision the limits of the changes produced in the body by its absence. In spite of this fact, a variety of disturbances have been attributed to vitamin B deficiency and while our views regarding these lesions may have to be revised later, it is well to review the current notions about them, particularly as they are seen in patients. The various fractions of vitamin B have been divided into the anti-neuritic factor (B1 or F), the pellagra preventive factor (B2 or G), and several other fractions which are supposed to be necessary for weight maintenance and growth. The lack of the anti-neuritic fraction leads to changes in the central and peripheral nervous systems with resulting retrobulbar neuritis, abducens, facial and vagal paralysis and peripheral neuritis. Table III summarizes the pathologic as well as the clinical lesions attributed to vitamin B deficiency.

TABLE III

VITAMIN B DEFICIENCY

Pathologic Lesions	Clinical Features
Central Nervous System Lesions	Abducens Palsy Facial Paralysis Recurrent Laryngeal Paralysis Retrobulbar Neuritis
Peripheral Nerves	Peripheral Neuritis
Heart Muscle Lesions	Cardiac Insufficiency Pellagra (?) Acrodynia (?) Combined System Disease (?)

The peripheral neuritis due to vitamin deficiency cannot be distinguished clinically at least from peripheral neuritis due to other causes. The lower extremities are involved more often than the upper and there are changes both in sensation and motor function. As in other forms of neuritis, touch is often lost over a greater area than pain or temperature. At this point it is interesting to note that patients with polyneuritis as a result of chronic alcoholism usually develop pellagra or peripheral neuritis after a prolonged alcoholic bout which is usually accompanied by a great reduction in the food intake. It is likely, therefore, that vitamin B deficiency plays a part

in the development of polyneuritis following chronic alcoholism.

In recent years it has become generally accepted that pellagra is a deficiency disorder and in some circles, at least, it is thought to be due to a lack of fraction of vitamin B known as the pellagra preventive fraction. There is much evidence to support the deficiency hypothesis of pellagra. Besides the characteristic skin lesion of pellagra other clinical features may be striking and include stomatitis, diarrhoea, peripheral neuritis, combined system disease, psychoses, anemia, and edema. Just how many of these clinical conditions can be attributed to the same cause as the skin lesions remains a question for further solution. In many cases it would appear that one was again dealing with multiple dietary defects.

The condition known as acrodynia or erythroedema polyneuritis or Swift's disease is considered to be an atypical form of pellagra by some observers, or a food deficiency of unknown cause by others. It is characterized by erythema of the hands, feet and face; particularly of the cheeks and nose, with desquamation of the palms and soles, excessive sweating, alopecia, insomnia, anorexia and peripheral neuritis. A disease in rats which has been interpreted as analogous to acrodynia in man, has been reported by Findlay and Stern and was produced by feeding autoclaved egg white. Inasmuch as most patients with this disease recover following a good diet, the evidence that it is due to a food deficiency is convincing.

Some patients with vitamin B deficiency develop cardiac insufficiency. The patients, who develop this condition are those who have slight involvement of the central nervous system and a preservation of muscular power. If they are able to carry on normal activities, a burden is placed on the heart which is already embarrassed by deficiency of vitamin. This causes a failure of the myocardium. If, on the other hand, the nervous system is extensively involved, so that polyneuritis develops, the patient is unable to carry on normal activities. As a result, the burden of exercise is not placed on the heart and failure does not occur. Exceptions to these observations are seen in infantile beriberi in which cardiac insufficiency occurs without exercise.

The clinical features presented by these patients may be summarized as follows: Most of the patients complain of palpitation, edema and some shortness of breath on exertion. These symptoms sometimes are preceded by pains in the calf muscles. If the patient is seen early in the course of his illness, it is noted that the heart rate is somewhat accelerated. The blood pressure might be normal. There are no conspicuous changes in the peripheral vessels. The heart is enlarged both to the right and to the left of the midsternal line; the apex beat is diffuse, and not forceful. There is usually a systolic murmur

over the pulmonary area, and the pulmonary second sound is accentuated. The lungs do not show signs of congestion, and the liver is not enlarged. There is usually edema of the lower extremities.

As the disease progresses, all these signs become exaggerated and the edema increases. The liver becomes enlarged, and nausea and vomiting sometimes appear. Striking changes occur in the peripheral circulation. There might be increased peripheral pulsations of the vessels of the neck and extremities, with a collapsing type of pulse and capillary pulsation. The sounds over the brachial and femoral arteries are increased. Examination of the heart reveals an increased enlargement with a systolic apical thrill, and loud systolic murmurs over the mitral and pulmonary areas. The rhythm, however, remains regular and it seems clear that the common arrhythmias do not occur in this disease. Teleoroentgenograms of the heart reveal enlargement of the right auricle and the right ventricle, with a prominent pulmonary artery and superior vena cava. The electrocardiograms do not show anything characteristic. The voltage might be low or high. Minor abnormalities, such as changes in the T waves, may be present.

All these conditions may occur in the cardiovascular system with slight changes in the nervous system. The latter generally consist of minor sensory disturbances and a loss of the knee and ankle jerks.

When the patient is treated with rest in bed with large amounts of vitamin B and a proper diet, striking improvement rapidly occurs. The heart rate falls, the blood pressure becomes normal, the peripheral pulsations and the collapsing and capillary pulse vanish, diuresis sets in, the heart becomes smaller, the murmurs disappear, and the patient becomes normal. The deep reflexes do not reappear until many weeks after the cardiac signs disappear.

In recent years, combined systemic disease has been suspected to be a deficiency disorder. This view gains support from the clinical observation of its occurrence in pellagra, pernicious anemia, also beriberi, lathyrism, ergotism, chronic dysentery, and carcinoma of the stomach. Animal experiments by Gildea, Kattwinkel, and Castle⁶ and by Mellanby⁷ have shown that lesions not unlike those in human cases of combined system disease can be produced by deficient diets. The precise nature of the deficiency is not definitely settled since Castle's results were obtained following a diet deficient especially in vitamin B, whereas Mellanby's results were observed on vitamin A deficient diets. At the present time, the fact of importance is that the lesions of subacute combined sclerosis have been produced in animals on deficient diets, and this disorder should, therefore, be considered a deficiency disease and should be studied from this viewpoint.

Apart from the conditions mentioned as signs

of beriberi, Hoobler⁸ has called attention to disturbances in infants which he feels are the result of a partial lack of vitamin B in the diet. These symptoms include irritability, anorexia, loss of weight, retardation of growth and rigidity. All of these conditions have been observed to disappear following the addition of adequate amounts of vitamin B to the diet in the form of wheat germ oil and yeast. These observations emphasize the importance of giving optimum amounts of essential food substances to all patients.

Vitamin C Deficiency. Scurvy of the infantile or adult type is due to a lack of vitamin C. The pathologic lesions observed are increased capillary permeability with resulting hemorrhage changes in the bones causing increased fragility, and changes in the bone marrow causing anemia. The hemorrhages in scurvy may be extremely widespread. They are especially prone to appear in areas which are traumatized such as in the masseter muscles, about the gums, in the muscles of the legs, into the knee joints, and in infants and growing children into the periosteum. Hemorrhages also occur at the costochondral junctions and occasionally from the intestine or kidney. The hemorrhages into the skin are of two varieties, those resulting from trauma are large ecchymoses or sugillations appearing over the legs. The ones occurring spontaneously appear about the hair follicles and are present only in the parts of body supplied with hair. These hemorrhages may occur without an associated hyperkeratosis follicularis. Petechial hemorrhages may also be produced by applying a tourniquet test.

The changes in the blood vary with individual cases. In some cases the clinical features of scurvy may be present without anemia. In others anemia is present. Mettler, Minot, and Townsend⁹ have studied the anemia of scurvy in man and found that blood regeneration followed the feeding of food rich in vitamin C. In spite of the fact that hemorrhage is a feature of this disorder, it has not been possible to demonstrate any defects in the substances which are responsible for normal blood coagulation. The blood platelets are normal, the clotting and bleeding times are normal, and the clot retracts.

Besides the changes in the blood vessels in the resulting hemorrhage, Aub and Salter have shown that there is a disturbance of the calcium metabolism in scurvy which leads to fragility of the bones; this is reflected in the presence of fractures particularly of the "green stick" variety which are common in children with scurvy.

There are other clinical features which may be observed in patients with scurvy but they are less constant and probably are due to a lack of substances other than vitamin C. They are cardio-respiratory disturbances, polyneuritis, edema and night blindness. Inasmuch as these conditions are observed as characteristic features of other de-

ficiency disorders, it is likely that when they are present in patients with scurvy the cause is a multiple deficiency disorder.

TABLE IV
VITAMIN C DEFICIENCY

Pathologic Lesions	Clinical Features
1) Increased Capillary Fragility	Hemorrhages into skin Muscles Sub periosteum Joints
2) Fragility of Bones	Gums, if traumatized Bone marrow— <i>anemia</i> Internal organs— <i>Intestinal bleeding</i> <i>Hematuria</i>

Rickets, Osteoporosis and Osteomalacia. It is now generally recognized that these various diseases of the bone result from the lack of absorption or proper utilization of calcium and phosphorus in amounts necessary to meet the requirements of the body. Knowledge concerning these conditions has been summarized recently by Marble and Bauer¹⁰ and they point out that some of the conditions are 1) dietary insufficiency of either calcium or phosphorus, 2) deficiency of vitamin D, 3) diets containing a great excess of calcium over phosphorus or vice versa, 4) longstanding diarrhoea, 5) any disease hindering absorption from the gastro-intestinal tract, 6) longstanding biliary or intestinal fistulas and 7) excessive excretion of fat. Reference to Table V will indicate the clinical conditions in which these disorders are observed.

Tetany. What has been said regarding rickets, osteoporosis and osteomalacia also applies to tetany which results from a deficiency of calcium. It must be remembered that tetany may occur as a result of parathyroid deficiency (post-operative or hypoparathyroidism of unknown etiology), but in these instances the mechanism is different from those cited above. Increased loss of calcium from the body such as occurs in lactation, or increased demands for it such as occurs in pregnancy, may also account for some cases of tetany. In any event it is necessary insofar as it is possible to determine the mechanism by which the deficiency of calcium arises, if a satisfactory permanent therapeutic result is to be obtained.

TABLE V
VITAMIN D DEFICIENCY

Pathologic Changes	Clinical Features
Disturbed Ca and P Metabolism	Rickets Osteomalacia Osteoporosis Tetany Dental Caries

Protein Deficiency—Edema Disease—Malnutrition Edema: When the protein intake of the diet is restricted for prolonged periods of time, the proteins of the blood are reduced in amount. This change predisposes to the development of edema. Edema disease has been recognized as a deficiency disorder for many years, and in time of famine or when the protein food has been restricted, it may occur in epidemics. Moreover, it has been described in connection with deficiency diseases such as pellagra, beriberi, scurvy, and it may be observed in a variety of other clinical conditions. Reference to Table I shows that the disorders in which it may be observed are numerous.

TABLE VI

PROTEIN DEFICIENCY—NUTRITIONAL EDEMA

Decreased Total Serum Proteins	Edema
Low Basal Metabolic Rate	Bradycardia
Decreased Blood Fibrinogen	Purpura

The clinical features presented by these patients are striking. (See Table VI.) The outstanding feature is edema which varies from moderate edema of the dependent parts to a generalized anasarca with puffiness of the face, edema of the chest wall and over the back, pleural effusion, ascites and effusion into the knee joints. Ascites is more common than pleural effusion and while pericardial effusion may be observed, it is much less common than effusion into the other serous sacs.

The skin may be rough and dry and in some cases typical hyperkeratosis follicularis is observed when there is an associated vitamin A deficiency. In other cases punched out ulcers appear over the legs. Hemorrhages into the skin and sclerae are observed without other manifestations of scurvy.

The temperature in uncomplicated cases is usually normal, but inasmuch as many of these patients develop infections, it is not unusual to observe fever of mild degree. The pulse rate varies tremendously, the bradycardia described by Burger as a characteristic feature of the disease is not constant and many cases are observed with slight tachycardia. The blood pressure is either normal or low. The heart is not enlarged, and there are no signs of cardiac insufficiency. The electrocardiographic records do not show any alteration in conduction, although left ventricular preponderance, even when the diaphragm is not elevated as a result of ascites, is common. The absence of changes in the cardiovascular system, when contrasted with the changes observed in vitamin B deficiency is striking.

Considerable variations in the basal metabolic rate are observed during the course of the disease. Usually when the edema is most marked, the basal metabolic rate is reduced below normal, during recovery it returns to normal, and in many instances it is elevated 20 to 25 per cent above normal for several weeks and then returns to a normal level again. Similar changes in basal metabolic rate have been observed in patients with undernutrition following typhoid fever, and it is likely that the changes observed in malnutrition edema are in some way related to the metabolism of undernutrition.

The blood does not reveal any characteristic changes in the red blood cells or hemoglobin. In a group of patients reported elsewhere¹¹ it was found that anemia was a variable feature. It was present in some cases and not in others.

One of the outstanding characteristics of the blood is a reduction of the serum protein. In a recent study by Weech and Ling¹² it was found that when the level of serum albumin was greater than 2.9 grams per 100 c.c. edema was never observed and when the level fell below 2.5 grams per 100 c.c. edema was invariably present. They also found that the serum globulin was exceedingly variable; decreased, normal or increased values were found in association with edema. These authors also stressed factors other than the decreased serum proteins in the production of edema in these patients, and pointed out that when the serum protein was low, the administration of sodium in the form of sodium chloride or sodium bicarbonate led to a marked increase in edema and a depression of chloride excretion in the urine. It appears, therefore, that while the level of the serum protein is of importance in predisposing these patients to edema there are other factors of importance in influencing the amount of fluid retained.

The renal function in these patients is usually normal.

One clinical feature which may be observed is diarrhoea. Although the symptom results from dysentery in some of these patients, it may be observed in edema disease when dysentery cannot be demonstrated. The diarrhoea may appear after the edema.

As in all deficiency disorders infections are common. In some cases, as in those with chronic diarrhoea, the infection precedes edema. In others, the infection follows the state of undernutrition. Tuberculosis, infectious arthritis, or non-tuberculous pulmonary infections are frequent.

There are several common conditions in which edema is influenced somewhat by malnutrition and require some comment, namely, cardiac insufficiency, anemia, and cirrhosis of the liver and diabetes mellitus. Payne and Peters¹² and others have noted that the albumin deficits in patients

with cardiac insufficiency appear to be directly referable to malnutrition. I have made similar observations, and in some patients in whom the usual methods of treating congestive heart failure with digitalis and diuretics have failed to cause the edema to disappear entirely, the feeding of a high-protein diet has been followed by a disappearance of the edema and an increase of the blood proteins. The same state of affairs I find exists in patients with edema associated with anemia, and my associate, Dr. Myers, has observed a reduction of the blood proteins in some patients with cirrhosis of the liver and generalized edema. The treatment of protein deficiency is high-protein feeding with protein of good biological value. It has been demonstrated by Liu²⁴ that protein of animal origin is of better quality than that of vegetable origin, and in a patient with malnutrition edema, recovery occurs more rapidly following the ingestion of protein of animal origin than it does following vegetable protein.

It is important, therefore, when dealing with patients with edema, to determine whether or not there is a deficit of the blood serum protein, and, if so, it should be treated accordingly.

ANEMIA AS A DEFICIENCY DISORDER

For many years certain types of anemia have been considered to be due to malnutrition but it has only been since the highly important work of Whipple, Robschiet-Robbins and their associates that the value of various food substances as building stones for hemoglobin and red blood cell formation has been fully appreciated. The discovery by Minot and Murphy in showing the specific effect of liver and liver extract in pernicious anemia has emphasized the great importance of food substances in the treatment of the human anemias. The observations of many other investigators in defining the usefulness of liver, iron, and other substances in other forms of human anemia has advanced our knowledge of the anemias considerably.

In considering anemias as a manifestation of a deficiency disease, it is important to realize that it often occurs under precisely the same circumstances as other deficiency diseases, namely, inadequate diets, disorders of the gastro-intestinal tract influencing normal nutrition and excessive demands.

It should be added that since the work of Castle and his associates a deficiency disease such as pernicious anemia may develop as a result of a disorder of the stomach which prevents the manufacture of sufficient amounts of essential substance from certain food products.

In Table VII the conditions in which malnutrition or a deficiency of certain substances in the diet are responsible in part for anemia are summarized.

TABLE VII
CONDITIONS IN WHICH MALNUTRITION IS A FACTOR IN THE PRODUCTION OF ANEMIA

- (1) Inadequate diets including avitaminosis.
- (2) Chronic dysentery.
- (3) Hookworm infestation.
- (4) Pregnancy.
- (5) Tuberculosis of the intestines.
- (6) Sprue.
- (7) Celiac disease.
- (8) Malabsorption of fat.
- (9) Partial and complete gastrectomy.
- (10) Multiple intestinal structures.
- (11) Chronic alcoholism.
- (12) Chronic hypochromic anemia (achlorhydric anemia).
- (13) Some cases of cancer of stomach and intestines.
- (14) Biliary fistula (external).

The table requires little comment. It is observed that the anemia which is associated with a great variety of conditions results in part at least from malnutrition. The importance of recognizing that anemia is the result of malnutrition in the conditions mentioned is twofold, namely, that it may be prevented by providing in the diet hemoglobin and red cell building substances and secondly, if anemia be present, it can be treated adequately with the same substances. In some cases, the treatment with iron is adequate, in others it is necessary to supply liver, liver extract or other substances which are potent in blood production, if recovery is to be expected.

Multiple Deficiency Disorders: It was stated in the introduction that deficiency disorders in man were seldom, if ever, single. This, undoubtedly, accounts for the variation in the clinical picture presented by many patients with one or another deficiency disease. For example, it has been stated that many patients with scurvy have night blindness. We know now that when the two occur together it is the result of vitamin A deficiency as well as a deficiency in vitamin C. A number of cases of multiple deficiencies are given in Table VIII, and it may be seen that many combinations may be present in various patients. An appreciation of the presence of multiple deficiencies is of importance in analyzing the clinical features of a case and also from the point of view of adequate treatment. In Table VIII, there is presented a group of cases of multiple deficiency disorders, and it is observed that a great variety of multiple defects may be noticed.

TABLE VIII
CASES OF MULTIPLE DEFICIENCY DISORDERS IN ADULTS

- (1) Keratomalacia and Beriberi.
- (2) Keratomalacia and Rickets.

- (3) Keratomalacia, Rickets and Beriberi.

- (20) Tetany and Edema Disease.
- (21) Pernicious Anemia and Scurvy.
- (22) Pernicious Anemia and Pellagra.
- (23) Pernicious Anemia and Edema Disease and Osteoporosis.
- (24) Pellagra and Subacute Combined Sclerosis.
- (25) Pellagra, Osteomalacia and Tetany.

Importance of Tissue Changes Resulting from Deficiency Diseases in Predisposing to Infection: It is now generally admitted that the tissue changes resulting from vitamin deficiency and particularly vitamin A often predispose the patient to infections. These infections have been emphasized in the experimental animal, and also have an important bearing on infection in children and adults. For example, keratomalacia is frequently associated with infection of the eyelids with blepharitis, meibomitis, and hordeolum. The associated hyperkeratosis follicularis may progress so that infection occurs about the lesions, and pustules and ulcers appear. Bronchopneumonia, which is so common in the experimental animal is also common in patients with vitamin A deficiency and the fatal case recorded by Wilson and Dubois¹⁶ showed that there was a hyperplasia of the bronchial epithelium to such an extent that the smaller bronchioles were actually occluded in some areas. With the appearance of such changes in the epithelium it is not surprising to find that infection is common under these circumstances.

Of further interest are the lesions of the intestinal tract. Tilden and Miller have shown recently that monkeys fed on a vitamin A deficient diet often develop an ulcerative colitis and they

interpret these findings as due to an infection superimposed on the changes in the intestinal tract. The occurrence of dysentery in patients with vitamin A deficiency is well recognized and Pillat has described patients with vitamin A deficiency and diarrhoea in whom the diarrhoea disappeared with recovery from the deficiency. In his cases bacillary dysentery was excluded by careful bacteriologic examination of the stools. Diarrhoea and ulcerative colitis, not due to dysentery has been described as a complication of edema disease.

It has been reported by McCarrison that monkeys infected with amoebic cysts continue to carry them without developing active amoebic dysentery until they are given an inadequate diet. Following this procedure, active dysentery appeared.

Periodontal infection and dental caries have also been attributed to dietary deficiencies and the question has been studied especially by Mellanby¹⁸ and reviewed recently by Hanke.¹⁷ Mellanby is of the opinion that vitamin A deficiency predisposes to periodontal infection, whereas Hanke attributes these infections to a lack of vitamin C. Dental caries, on the other hand, have been produced in animals as a result of vitamin D deficiency.

It is seen, then, that deficiency disorders predispose patients to infections as a result of tissue changes, and as these changes may be widespread and affect all epithelial tissues, the manifestations of infection may likewise be extensive.

I have observed obscure pyrexia, arthritis, phlebitis, ulcerative colitis, bronchopneumonia, and pyoderma in patients with deficiency disorders. The precise relationship between all of these infections and deficiency disorders is not clear, and further investigations in this field are necessary before final conclusions can be made. It is essential, however, in studying obscure infections to appreciate that they may develop in tissues made susceptible by changes resulting from food deficiencies.

SUMMARY AND CONCLUSIONS

The clinical features of some food deficiency disorders in man are presented and discussed. It is evident that these conditions are observed not only following restricted diets, but also when pathological processes interfere with nutrition. Multiple dietary deficiency disorders often occur in the same patient and an appreciation of this fact is necessary to establish adequate treatment. Deficiency diseases often predispose the patients to secondary infections.

RELATIVE ADVANTAGES OF TOXIN-ANTITOXIN AND TOXOID*

By WILLIAM A HOLLA MD, WHITE PLAINS, N Y

From The Department of Health of Westchester County

DURING the past few months the Westchester County Department of Health has Schick tested 1500 children who had received three doses of toxin antitoxin during the period of 1927 to 1931. The results showed that of these only 67 per cent were immune, in contradiction to the commonly accepted statement that of children receiving three doses of toxin antitoxin 85 per cent are immune to diphtheria. In other words, these results indicate that parents and guardians of young children are being given an exaggerated sense of security as a means of persuading them to have their children immunized. Undoubtedly by giving larger doses of toxin-antitoxin or more than three doses a greater number of immunes would be obtained. Neither procedure is desirable. It is for this reason that in cooperation with the Laboratories of the State Department of Health we are making a study of three preparations of so called toxoid which is being advocated more and more by those who are not wholly satisfied with the results obtained by toxin antitoxin.

The toxoid which was used in these comparative studies was prepared by the Division of Laboratories and Research of the State Department of Health. There were three preparations (a) a veal infusion toxoid prepared according to the method of Ramon (b) an infusion free toxoid also prepared according to the method of Ramon but with the toxin described by Wadsworth and Wheeler¹ and (c) a preparation of this infusion free toxoid refined according to the present methods of Wadsworth, Quigley and Sickles².

The antigenic or flocculation unit strength of the refined infusion free toxoid was 156 units per c c. To secure an impartial test, the three kinds were numbered and known only to those supplying them at the Albany Laboratory. The dosage used with each type was the same, namely, first dose 0.5 c c, second dose 0.5 c c, third dose 0.5 c c, all being given at weekly intervals and local or constitutional symptoms recorded. The refined infusion free preparation gave the best results, as there was very little pain upon injection, no discomfort during the succeeding week, the local reactions were not encountered in the age group up to nine years and few in the ten to fifteen year group and not of a serious character, consisting of some local redness, swelling and pain about the site of injection. It was noted that intramuscular injections were less frequently followed by such reactions. In the older group the initial injection was 0.3 c c, followed by the regular 0.5 c c weekly injection. At the beginning a subcutaneous test was made, but as this type of toxoid apparently gave few reactions, this was discontinued and doses of 0.3 c c, 0.5 c c, 0.5 c c were given. The veal infusion toxoid apparently caused more pain on injection, gave more reactions. However, none of the reactions were any greater than those seen with toxin antitoxin and the resulting pigmentation from superficial doses of toxin antitoxin was not seen.

Reactions occurred in 33 cases of the 1258 treated (26 per cent), with one or other of the three preparations used. In the preschool group there were seven reactions, which gives (0.05 per cent). Reactions were as follows: redness 17 cases, swelling 1 case, red and swollen 6 cases.

* Read at the Annual Meeting of the Medical Society of the State of New York at Buffalo, N. Y., May 23, 1932.

redness and induration 8 cases, redness, swelling and induration 1 case. The age groups were respectively as follows: 1 year, 3; 5 years, 1; 6 years, 1; 7 years, 2; 8 years, 2; 9 years, 8; 10 to 15 years, 16. From this it will be seen that about one-half of the reactions occurred in the group up to ten years (.013). As most children attending clinics are under ten years, it is apparently safe to use the toxoids, especially the refined toxoid, without first testing.

All clinics for diphtheria immunization in the Westchester County Health District are using toxoid as a routine method and the use of toxin-antitoxin has been discontinued. No child is given toxoid if over ten years unless a positive Schick test has been obtained. The ages were six months to fifteen years, the majority being under eight years. At the present time the minimum age is four months. In children under one year, if the Schick was negative they were given the three doses of toxoid, it being believed they were protected by maternal immunity, and as such immunity would soon disappear, it was essential that they be protected. All cases reported in this series were given a preliminary Schick test and one dose of toxoid at the first clinic. If the result of the Schick was positive, two more doses were given at weekly intervals and within three to five months a subsequent Schick was made and the result tabulated. In the future, the preliminary Schick will be omitted, as the great percentage are positive, but in order to obtain accurate statistics it was performed in the series reported. Weekly intervals of doses were used, as it was easier to hold clinics at succeeding weeks and have a larger percentage return than would be the case at monthly ones. It also obviated considerable work, as only the original visit was made to have the child attend, whereas if held at monthly intervals two follow-up visits would be required. In some areas considerable transportation of children was necessary and this was accomplished more readily by giving treatments at weekly intervals.

The total number of cases treated with one of the three toxoids was 1258, of which 453 re-

turned for a subsequent Schick test within four months with the following results:

Negative to Schick—													
Under 1	1	2	3	4	5	6	7	8	9	10	to 15		
	38	90	49	39	39	49	51	29	16	21	21	Total	442
Under 6 years	304			Negative to subsequent Schick—									
	98.06%.												
6 to 15	138			Negative to subsequent Schick—96.5%.									
Total negative to Schick—442													
Total positive to Schick— 11									Immune—97.57%				
(a) Veal Infusion Toxoid													
Treated and Schicked										89			
Negative to subsequent Schick										86			
Positive to subsequent Schick										3		Immune 96.62%	
(b) Infusion Free Toxoid													
Treated and Schicked										210			
Negative to subsequent Schick										204			
Positive to subsequent Schick										6		Immune 97.1%	
(c) Refined Infusion Free Toxoid													
Treated and Schicked										143			
Negative to subsequent Schick										141			
Positive to subsequent Schick										2		Immune 98%	

All Schicks were made between the third and fifth month following last dose of toxoid.

It is hoped to obtain an immunity at the end of four months with the injection of two doses of refined toxoid and at the present time a series of clinics are being held in which two doses of 0.5 c.c. each are being given at weekly intervals; another group with 0.5 c.c. at monthly intervals; and one with an initial dose of 0.5 c.c. followed in four weeks by 1 c.c. These cases will be Schick tested within four months and the results reported.

Until the latter part of the year no child giving a history of asthma was treated, but as few reactions occurred, it was decided to treat a few cases with asthmatic conditions. In none of these was there any change in the child's condition.

In one instance, a child had given three series of toxin-antitoxin each year for the past three years and was still markedly Schick positive. Within four months of receiving three doses of refined toxoid it was Schick negative.

MATERNAL MORTALITY

By ELIZABETH M. GARDINER, M.D., ALBANY, N. Y.

IT is apparent to any student of maternal mortality that from the many studies that have been published, we know a good deal about the immediate causes of puerperal deaths, a little less about the contributory

causes, and little or nothing about those disease states that may have existed closely prior to or during pregnancy which may have had a bearing on the fatal outcome.

Death certificates at best yield a paucity of

information. When the facts derived from this source are assembled and treated statistically, we do obtain some guidance for the better promotion of preventive effort, in that there is a confirmation of generally existing views as to the relation of age of mother, incidence of hospital or home delivery, the influence of illegitimacy, twin births, nationality, geographical distribution and other pertinent factors.

Without the least reference to any tomes on the subject of maternal mortality, we know that puerperal sepsis, albuminuria and convulsions, and hemorrhage are the three most important stated causes of maternal mortality accounting for practically sixty per cent of the whole number of maternal deaths. It is frequently stated that we have adequate knowledge of the means of prevention, and yet fail to succeed in this endeavor.

We are now emerging from a state of self-castigation for what has been considered a wholly indefensible position as to the maternal mortality rates for the United States as compared with those of European countries. It is quite possible, in fact probable, that the different bases of interpretation and statistical methods employed in the different countries, not to mention the wide difference in variables, make the various rates incomparable, or if they are comparable, we have not now sufficient conclusive data to prove the point. This has already been set forth in the Report of the New York State Health Commission. (See *Public Health in New York State, 1923*, page 262.)

Can we not, for the moment, forget comparative rates? It matters little, really, from the point of view of objective, whether we know New York State's maternal mortality rate, or whether it is higher or lower than that of other states, or for the whole United States, or for Denmark or England. For the goal we are trying to reach, it is convincing enough to know that between five hundred and six hundred New York State mothers die from childbirth every year, year in and year out, and to realize that this is not the whole story; that for every two mothers who die a baby dies also; that many homes are disrupted and motherless children subsequently distributed in orphanages, boarding homes, or in the homes of over-burdened relatives; some of them finally reaching the courts as delinquents or dependents to become state wards.

We have at least two good reasons for continuing our studies of maternal mortality:

1. That while it is assumed that we have knowledge of the means of prevention, we have not yet evolved a perfect plan or even a moderately efficient plan that is so practical

that it can be carried out easily with a sufficiently large proportion of expectant mothers to reduce the mortality.

2. That the volume of mortality implied in the loss of mothers and infants and the economic and social factors involved, in themselves, demand continued serious study.

The New York State Department of Health has been actively interested in the matter of maternal mortality since 1922 when, by the passage of the Davenport-Moore Act, it was specifically charged with the function of the promotion of measures for reducing the number of maternal deaths.

The late Director of the Vital Statistics Division, Dr. Otto Eichel, contributed several statistical studies dealing with this subject. Dr. O. V. DePorte, the present Director, has also published an able and exhaustive study. Dr. Matthias Nicoll, Jr., former Commissioner of Health, delivered an epoch-marking paper on maternal mortality as his presidential address before the State and Provincial health authorities of North America in May of 1929. In 1932 the New York State Health Commission, appointed by Governor Roosevelt, devoted several pages of its report to a consideration of maternal mortality and called attention to a study of fifteen hundred maternal deaths by the Ministry of Health in Great Britain in which it was shown that not less than half of the deaths studied were preventable and that the primary avoidable factors as determined were as follows:

	Per cent
Faulty ante-natal maternal care	36
Error in judgment on the part of physician, midwife, or hospital	36
Lack of facilities	10
Negligence of patient	18

In the Commission Report the recommendation is made that the State Department of Health investigate, for at least one year, every maternal death upstate by careful epidemiological methods, in cooperation with the local medical society, and endeavor to determine the primary avoidable factor in producing the fatal result.

Between 1924 and 1927 the Divisions of Vital Statistics and Child Hygiene collected confidential data, by questionnaire, from the practicing physicians of the state in which there was more than 80% voluntary return. The questionnaire study is still in the process of completion, and will, unquestionably, yield new information of a helpful character, although the very quantity, variety and complexity of the material make it difficult to arrive at conclusions without tedious and exhaustive study. Some of the findings, however may be briefly stated at this time for the rea-

son that they offer some suggestion as to the direction in which future efforts should be pointed.

Less than half of the deaths studied were associated with the birth of living infants.

In about half of the delivered cases the infants were less than full term, and in over 30% less than seven months gestation.

The mortality of mothers of twins was two and one-half times the general rate.

Abortion was a causal or associative factor in nearly one-fifth of the deaths, and a contributory factor in one-third of the deaths from sepsis.

Abortions were associated with a third of deaths of unmarried and nearly a fifth of the married mothers.

Adequate prenatal care was reported to have been had by 58% of the delivered cases, but in half of these the patients had not consulted the physician earlier than the seventh month and a fourth of them much later.

Nearly four-fifths of the delivered cases died in hospitals, but a fourth died in the hospital after having been delivered outside.

Nearly half of the deaths had had some type of interference.

In 729 operative cases there were 212 Caesareans, 151 Versions, 130 Low forceps, 97 High forceps, 15 Manual extraction of placenta.

Of 229 deaths in which labor had been induced 75 were self-induced, 71 therapeutic, 22 criminal, 61 manner of induction not stated.

Of the group in which there was interference (937), 31% died of sepsis as against 40% dying from sepsis in the non-interference group, (598).

In the latter group 23% died of albuminuria and convulsions, 9% died of hemorrhage.

In the interference group 25% died of albuminuria and convulsions, 15% died of hemorrhage.

Correlating the type of interference with the three important causes of death, sepsis, albuminuria and hemorrhage, we found that 16% of the Caesareans died from sepsis, 35% from albuminuria and convulsions, 14% of the versions, from sepsis, 26% albuminuria and 40% hemorrhage.

In the cases registering the use of low forceps, 28% died of sepsis, 28% died of albuminuria, 15% died of hemorrhage.

In the high forceps group, 28% died of sepsis, 25% albuminuria.

Eleven of the 15 deaths where there had been manual extraction of the placenta, died of sepsis. There were no deaths from hemorrhage in the Caesareans, high forceps nor in the manual extractions of the placenta.

In the induced labor group 87% of the self-

induced died from sepsis; none from albuminuria or hemorrhage.

Of the therapeutic induced 15% died of sepsis and 55% from albuminuria; none from hemorrhage.

Of the 83 deaths, comprising 22 criminal and 61 manner of induction not stated (36% of the induced labor) all died of sepsis.

More than half of the questionnaire deaths had complications of pregnancy, chiefly the toxemias, placenta praevia, malposition, abnormal pelvis and retention of dead fetus.

About 30% of the questionnaire deaths had illnesses previous to pregnancy which were thought by the attending physician to have possibly affected the outcome. In this complicated group, it was heart disease in 20% of the cases, kidney 20%, the anemias 12%, metabolic or deficiency diseases 10%, infectious cystitis 7%, respiratory disease 3%. "other infections" 6%.

These factors resolve themselves finally into a consideration of Prematurity, Loss of infant life, Twin births, Illegitimacy, Abortion as a cause and as a vitally contributory factor in sepsis, Inadequate prenatal preparation, High incidence of emergency cases, Interference as contributory to sepsis and hemorrhage and as a measure possibly too delayed of application to deal successfully with eclampsia, Complicating disease, puerperal and non-puerperal.

These items strongly suggest the need for a more comprehensive application of medical diagnosis and foresight during the whole nine months of pregnancy. To be sure there is little in the way of specific precaution that the physician can advise during the prenatal period that will insure an individual against sepsis, but it ought to be possible to energize an educational movement against abortion for other than therapeutic reasons, and by early diagnosis and intelligent care during the prenatal period reduce the frequency of the need for later operative procedures.

Notwithstanding the gloomy character of the facts just enumerated, we should not be led too hastily into making pessimistic assumptions; thousands of mothers may have had some type of interference and survived, or may have carried through their pregnancies handicapping diseases and passed through the ordeal of childbirth successfully. Until we study all pregnancies in a given area, or period, the survivors along with the fatalities, it will be impossible to gauge the degree of hazard of any of the situations that are thrown into sharp relief by studies of deaths exclusively. That such a study will be attempted eventually is certain, but our immediate duty is to improve our methods of studying mortality.

On January 27, 1932, Commissioner Parran

met with the Committee on Public Health and Medical Education of the Medical Society of the State of New York and presented a plan for the cooperation of the State and County Medical Societies in the study of maternal mortality. This plan was outlined in the annual report made by Dr. Thomas P. Farmer, Chairman of the Committee, to the House of Delegates of the State Society, (Journal, Apr. 15, 1932, p. 496) and was approved by the House on May 23, 1932 (Journal, June 15, 1932, p. 753). Dr. Farmer reported that one third of the County Societies had already approved the plan.

Dr. Farmer communicated with the secretaries of the county societies, outlining the objectives and nature of the proposed study, and suggested that the Public Health Chairman of the county societies act as local representatives of the state society in advising with local representatives of the State Department of Health concerning general methods and findings in individual cases.

The study in question is to include all deaths of women in pregnancy and childbirth occurring currently during 1932, the data to be secured as soon after the occurrence of the death as practicable by a qualified physician representative of the State Department of Health, except in those districts where there are County Health Units, when this function will be performed, or delegated by the County Commissioner of Health.

It was agreed that the information would be sought from three main sources:

1. The individual signing the birth or death certificate, or any and every physician or midwife who saw the case.
2. The hospital where death occurred, if in a hospital, for the post-mortem findings, laboratory data and pertinent facts from the case record.
3. The family, when advisable, for information as to economic status, previous illnesses, previous obstetric history or to supplement incomplete data from other sources.

The final report is to be a joint publication of the New York State Medical Society and the State Department of Health, and to be in all respects a confidential, scientific investigation which is made for the purpose of determining, as far as possible, the "primary avoidable factor" in each puerperal death. The method adopted is as follows:

As soon as the certificate of a puerperal death is received in the Albany office, which at present is the fifth of the month following the registration, the essential facts are trans-

ferred to a standard schedule, or form, and search is made for the birth, or possible death certificate for the infant. An investigation is also made to determine whether among the deaths of all women between fifteen and forty-five years of age there may be some deaths from another stated cause but in which, for one reason or another, we are led to believe pregnancy may have existed. Here again birth and death certificates of infants are searched for and matched with those of the mothers concerned.

The data from the birth, or death, certificates of the infants are also transferred to the inquiry form and questions pertaining to the listing of hospitals with the American Medical Association or the American College of Surgeons are also checked in the Albany office. In fact every effort is made to fill out as much of the schedule as possible in the department before sending it to the local representative for further attention.

Commissioner Parran's instructions require that the first call of the interviewer is to be made upon the President and Public Health Chairman of the County Medical Society to acquaint them fully with the purpose and method of conducting the study.

The results of the local inquiry and conclusions to be drawn therefrom to be discussed and agreed upon by the Chairman of the Public Health Committee of the county society and the State Department of Health representative.

All moot questions are to be submitted by the State Commissioner of Health to a Reference Committee comprising the Public Health Committee of the State Medical Society, the State Commissioner of Health, and such other members as suggested by the Reference Committee.

Needless to say the results of this study will be more valuable and indicative if the information given is as complete as possible, and because the inquiry is made within a reasonable time after the occurrence of the death, while the details are fresh in the minds of the attending physicians, it is hoped that we may secure much more conclusive information than has been obtained in our previous studies.

With the full cooperation of all parties concerned, it should be possible for the committee to give some preliminary figures at least, in the early part of 1933. It is hoped that the facts elicited may point the way toward not only a better understanding of avoidable factors, but provide practical suggestions for the better protection of expectant mothers in the State of New York and elsewhere.

MEDICAL ECONOMICS, A RENAISSANCE

By FREDERICK S. WETHERELL, M.D., SYRACUSE, N. Y.

The retiring president's address, read before the Syracuse Academy of Medicine, January 19, 1932.

IS the medical mind today undergoing a "re-birth;" is there an awakening of vital energies and intellectual powers, involving a new way of looking at the subject of economics as applied to the practice of medicine? It seems so without question, if one considers the great number of contributions on the subject by physicians, to say nothing of the opinions voiced by members of the profession in daily conversations with their fellows, and articles in the lay press.

Courage to attempt changes, which are no doubt revolutionary in character, and seem too radical to many, may be gained from the thought of Emerson, who said, "weak young men grow up in libraries believing it their duty to accept the views which Cicero, Locke, and Bacon have given; forgetful that Cicero, Locke, and Bacon were only young men in libraries, when they wrote these books." With this thought, Emerson proceeds with the elaboration of the idea that disagreement with the Past makes it incumbent upon us to break with it, no matter how great the prestige of its messengers. In no sense does he mean that we are to ignore in its entirety the work and thought of genius of other days, the heritage handed down to us; but with that work, and that thought as a guide and check, to alter our ideas and processes of thought so that they may meet the requirements of the age in which we live. Such a premise, surely, needs little affirmative argument when applied to the scientific aspects of medicine. The almost overwhelming number of contributions in the literature of Medicine bear testimony to the willingness, the desire for change and betterment in the applied science of Medicine. The Science of Medicine is secure.

The ultimate, however, in the practice of medicine is application of knowledge gained by scientific investigation to the problems of the sick individual. In the end, this means that the close relation of individual physician to individual patient must be maintained, kept intact as it has been in the past, lest both patient and physician suffer.

American ideals demand the continuation of opportunity for individual achievement. It is unthinkable that a state of affairs may come about, which will in the slightest approach European conditions of medical practice—where, in many instances, individual initiative has been entirely destroyed, and our professional colleagues reduced to penury. All of this often, because of insistence that the physician has no right to mingle in the business of State.

Who is it, pray, that is better qualified to direct the policies of the State relative to medical matters, which, naturally, in the final analysis means the continued health and the recovery from ill-

ness of the individual patient? It is difficult to keep from emotionalism when discussing this subject, but in some way the emotions of the profession at large must be stirred to the effect that interest will be aroused in the necessity of each practicing physician taking part in the official discussions, adding his counsel to the attempts at solution of the far-reaching problem of Medical Economics.

Ingrained in the medical mind, placed there by tradition, is an abhorrence of any thought which relates to matters pertaining to financial reward for service. Proper care of the sick is paramount in the physician's code, and this will never change.

Shun as we will, however, all thought of monetary matters, the fact remains that any unit, or group of units of society, functions well only in so far as its place in the community, its ability to share its burden in the upkeep of the body politic, is kept intact.

Content with things as they have been, many of the older members of our profession decry the apparent tendency of medical organizations to evaluate the doctor's place in society. They protest against the, as yet, poorly organized effort to supervise the activities of certain lay bodies who do not, and probably never will be able to, understand the manner of medical thought—they resent the attempts to see to it that the time-honored prerogatives of the medical profession are not nullified by ill-directed and meddling policies, which take no cognizance of the rights of individual practitioners of medicine. The ideas of these estimable members of the profession must not be ignored for they are a needed check, but their mode of thought must be tempered with a policy of open-mindedness.

Paramount in importance is the right of the physician, conferred upon him by the State, to protect the health of his patient and to serve him in time of sickness, so long as that service is on a par with the service delivered by fellow practitioners of the same group in his community. That there be no abrogation of this right is of prime importance to the patient. To make certain that there is none, is the duty of official medical organizations.

This means that a definite, well-directed effort must be made by the medical profession as a body, to the end that the health problems of that unit of society, the patient, may continue to receive the individual attention of his physician, and that both may retain their self-respect.

All of this involves change in time-honored customs. It is only by concerted effort that progress will be made. Widely divergent views must be made to converge. So far as we, as a group set aside, are concerned, our innate individualism

in matters of policy must be curbed, and our various thoughts thrown into a common mortar, so that the pestle of collective wisdom may grind out a medicament which, as nearly as is possible, will be a specific for the ills with which we are threatened.

After all is said and done, the ultimate benefit of a solution of the problem of Medical Economics, will be derived by the patient. The benefits accruing to the physician are incidental, and only of importance as they secure for him the means which enable him to deliver his services in an honorable and efficient manner.

Any solution of the problem must be such that in no way will State medicine supervene. There are those in our ranks, who feel that such an eventuality would not necessarily be harmful to them, which may be true to a certain extent, in that there will always be a demand for expert services by individuals able to pay for them. They must, however, be convinced that their less fortunate colleagues will be caught in a maelstrom of consequences, which they, themselves, may with difficulty keep out of, and which future generations of physicians can in no way escape. Intelligent public opinion today is not in favor of the plan, and it behooves us to substitute a better one.

What shall it be? What are the solutions? Any answer to these questions is conjectural at this time. A mass of problems is before us, and in this state at least, steps are being taken, gradually and carefully, with an ear to the opinions of the members of the profession, which it is hoped will, in time, effect a solution beneficial to all concerned.

The problems with which we are confronted, affect, to a large extent, the urban physician, and for that reason they are being brought to the attention of this body. The rural practitioner is, however, not by any means exempt from the effects of changes, which may take place. His interest in a possible solution must not lag.

A detailed discussion of the individual items involved in the general mass of the problem is here impossible. Volumes will be written before even one subdivision of the general question is answered.

Two main ideas must be considered. The first concerns the relations of the doctor of medicine, as an individual, to society, the individual members of which expect him to deliver to them, medical advice. The second concerns the relations of the physician to his confreres.

In the attempt to consider them separately, one finds a constantly recurring interdigitation of these two problems. A final solution of either demands solution of both.

Under the first heading, we find demanding attention, to mention only a few: compulsory health insurance, already on the statute books in the form of Compensation Insurance; the cost of

medical education; the cost to the physician for maintenance of his equipment and delivery of his services; care of the indigent and proper distribution of the cost of same; cost of sickness to the middle classes, which includes cost of hospitalization; court testimony; financing of sickness; public health problems; nursing problems; industrial clinics; diagnosis and treatment by irregulars; etc.; etc.; almost ad infinitum.

Already some of the attempts at bringing order out of this apparently chaotic jumble of problems, are nearing fruition in isolated instances. As aforementioned, it is not the purpose to discuss here the various intriguing angles, which present themselves during the unraveling of the tangled skein of medical economics, but to suggest the attitude, which must be assumed by the medical profession, if order is to be obtained.

First and foremost, we must demand of ourselves, as a profession, an unrelenting honesty of purpose and uprightness in our dealings with society and its component parts. The medical profession cannot expect the community to accede to its demands, or listen in a receptive mood to its suggestions, if its sincerity is open to criticism because of the unseemly activities of a few members of the profession. That instances of unprofessional conduct are isolated and are not condoned by the offender's colleagues, makes no difference to the layman—his confidence in the profession, as a whole, is undermined.

Practicing physicians are zealous in maintaining a high degree of integrity and professional conduct; and when the standards seem to be lowered, the offense is that of an individual, and may best be investigated and corrected by the county medical society whose members are familiar with local conditions. The task of straightening out difficulties is one for the older members of the society, who by their eminence, have shown themselves free from taint as is humanly possible. We will never attain a millenium, but without a beginning there can be no progress.

This State, by means of its representative medical body, in liaison with its Board of Regents, has already a functioning organization for the ironing out of alleged irregularities of medical practice. There is no reason why a local medical society should not appoint from its membership a grievance committee to hear charges of alleged misconduct of its membership. Such a group functioning in absolute secrecy could, it seems, do much toward nipping in the bud beginning irregularities. It is to be presupposed, of course, that the Organization will be of such value to the medical profession that physicians of the community will realize that they can ill afford to ignore the advantages accruing to them because of such a membership.

It should be the duty of such an organization to see that in the event of newly suggested treatments by, for example, a State agency, its mem-

bership is informed as to the *modus operandi*. This could be done under supervision of a committee on education and by means of clinics.

Usurpation of the rights of members by colleagues, or by lay bodies should be vigorously studied, and such action taken as will again show the individual member that it is well worth while to be a part of the organization.

The strength of the entire fabric of such a structure, however, rests in the willingness to accept self-imposed police power. Human frailties will come to the front repeatedly and must be handled judicially, and with human under-

standing. One cannot help believing that, until our own house is put in order, our own doorsteps swept clean and kept clean, little progress will be made in a solution of Medical Economic problems. This housecleaning will hurt no well-intentioned, honest physician, and at the same time with the only kind of paternalism that we should countenance—that from within our own ranks—will give opportunity for those who have strayed in the past, to step in line with their fellows, to the end that members of the medical profession may live as gentlemen, and the public receive the kind of medical care which it deserves.

THE PREVENTION OF COLDS

By D. F. SMILEY, M.D., ITHACA, N. Y.

From the Student Medical Service of Cornell University. Read at the Annual Meeting of the Medical Society of the State of New York, at Buffalo, N. Y., May 24, 1932.

QUESTIONNAIRE studies of our Cornell students have shown us that approximately 23% of the student body have colds four or more times a year and can, therefore, be classified as definitely "cold susceptible." Another group of 60% rarely have colds more than three times a year and these, therefore, we would call "average." A third fortunate group of 17% have colds never more than once a year and are, therefore, classified as "cold resistant."¹

When we first realized, back in 1924, that we had these two extreme "cold susceptible" and "cold resistant" groups with us, we thought that certainly it was going to be possible to demonstrate in these large numbers, significant differences between the two groups. But such did not prove to be the case. A careful study of the health habits of the two groups, "cold susceptible" and "cold resistant" yielded nothing. Those who had multiple colds ate, slept, exercised, smoked, clothed and cared for ventilation and elimination in very much the same way as did those who rarely if ever had colds. A comparison of the physical examination records of large numbers of "cold susceptibles" and normals, showed no significant differences.² Removal of tonsils and nasal obstructions did not seem to be a significant factor since 54% of our "susceptible" group had had one or more such operations while only 40% of our "resistant" group gave such a history. The "cold susceptible" group did, however, give a history of "cold susceptible" parents, and a history of past infectious diseases such as measles, mumps, pertussis, scarlet, etc., more often than did the "cold resistant" or normal group.

In the college year of 1926-27 we grouped 1625 students into "cold susceptible" (4 or more a year) and "normal" (never more than 3 a year)

groups and checked the cold incidence. In no week of the year did more than 13% of the normal group report a cold while in some weeks as high as 60% of the "cold susceptibles" reported colds. The cold epidemics were apparently a phenomenon belonging only to the "cold susceptibles" since the curve for normals, both men and women was carried thru the year without any peak of any significance.³

From all our comparisons between normals and "cold susceptibles" one fact did, then, emerge, i.e. apparently our cold epidemics were a phenomenon peculiar to our "cold susceptible" group, a group composing rarely more than $\frac{1}{4}$ of our student body.

The possibility then presented itself for making a direct attack on the incidence of colds in our student body, since the core of the problem lay right in the less than 1400 "cold susceptible" students (not an impossibly large group to handle even in its entirety). But supposing we could get our comparatively small group of "cold susceptibles" to join a "cold-prevention" class and let us put into operation all the preventive factors we could muster together, what factors would we apply? To this question there were many answers but they simmered down in our minds, to three main sets of factors—ventilation, diet, and toning up of the skin capillaries.

WINTER—THE SEASON FOR COLDS

Since 1912 when our records began, there has been no year when sometime in December, January, February or March we failed to note an epidemic of colds.⁴ At no time have these epidemics occurred in other than the dark, cold period of the year. Whatever the factors are that lower resistance to colds in our students in mid-winter, they also lower the vitality of the whole

population of New York State since the mortality curves for the State quite parallel our cold curves. These same factors also lower our working ability (see Ellsworth Huntington's graphs).

1. VENTILATION AS A FACTOR

The atmosphere of our lecture halls and recitation rooms throughout the winter months is apt to be hot, dry, quiet and considerably polluted by infective moisture droplets talked, coughed or sneezed out of the many throats. Windows are opened here and there and adequate mechanical systems of ventilation are in operation in a few of the more modern buildings, but in order to keep the feet warm and comfortable through the hour, the average lecturer or instructor has found that windows can be opened only very conservatively, if at all. Thus at the end of the hour, the student not infrequently steps out abruptly from a classroom with a temperature of 70° Fahrenheit and a relative humidity of 25 per cent into an outside atmosphere with a temperature of zero Fahrenheit and a relative humidity of 70 per cent. This marked difference in atmospheric conditions, the New York State Commission on Ventilation found results in a paling, a swelling and non-resistant condition of the mucous membrane of the nose, as well as in a decrease in the mobilization powers of the "immune bodies" in the blood stream. A charting of cold incidence at Cornell against average temperature, month for month throughout the period, 1912-1913 to 1924-1925, showed a definite reciprocal relationship between the two.⁴

2. DIET AS A FACTOR

The diet of our college students in spite of our efforts to popularize the "protective foodstuffs" such as milk, leafy vegetables and citrous fruits, is still short in these foods and as a result it is not uncommon to find the alkaline reserve at a point we would consider low or low-normal. And in mid-winter when the appetite for canned vegetables lags and the milk comes only from stalled cows, and the eggs from winter-housed chickens, a definite deficiency in vitamin intake is almost certain to occur.

Add to this deficiency the fact that many students on institutional fare frequently satisfy their craving for something tasty by over-indulging in candy, "sodas," chocolate and other confections thus leading to a frankly high or high-normal blood sugar and we can easily conceive of a general lowering of resistance to infection from faulty diet alone.

3. A "Coddled" SKIN AS A FACTOR

A skin which is but rarely exposed to cold air, sunshine ultra-violet light or cold water, becomes pale and very sensitive to changes of temperature

in the air about it. In such a skin very little vitamin D is formed from the irradiated ergosterol, but more important that that, the tone of the capillaries is so poor that in the presence of only moderate dampness or a draft, chilling of the circulation readily occurs and again a lowered resistance to infection follows. A checking of cold incidence at Cornell against average hours of sunshine, month for month through the period 1912-1913 to 1924-1925, showed a definite reciprocal relationship between the two.⁴

THE EXPERIENCE OF OTHER WORKERS

The reports of previous workers seemed to confirm our impression as to some of the important factors in preventing colds. Thus the New York State Commission on Ventilation reports a uniformly decreased incidence of colds among school children whose school rooms are ventilated by the modern modified-window method rather than by the mechanical method. Several workers report a decreased incidence of colds where the children's attention is rather continuously called through "no-cold campaigns" to such hygienic faults as sneezing or coughing with the mouth uncovered by a handkerchief. Other workers report that diets rich in the "protective food-stuffs" and particularly in butter, are very successful in reducing the incidence of colds. Dr. V. S. Cheney, of Chicago, states that it is frequently possible to prevent the occurrence of threatening colds by appropriate doses of alkali. At Cornell⁶ through two winters, 1926-1927 and 1927-1928, Dr. Geo. Maughan gave groups of cold-susceptible students weekly irradiations of ultra-violet light which corresponded roughly with the amount of ultra-violet light which the average student would obtain from the sun's rays on his neck, face, hands and wrists in ordinary clothing in mid-summer. The incidence of colds in the groups so irradiated was approximately 40 per cent less than in similar groups of cold-susceptible students which were being followed but not irradiated. Dr. Leonard Hill in England and Dr. Cecil in New York City in their texts on colds have reported favorably on the effects of sun bathing and ultra-violet light bathing in toning up the skin capillaries and thus aiding in the raising of resistance to colds.

THE "COLD PREVENTION" CLASSES

In the fall of 1929, then, with the help of Dr. George H. Maughan, we organized our first "cold prevention" classes and urged all of our "cold-susceptibles" to pay the nominal fee and register to receive the following services:

1. A fifteen-minute ultra-violet light bath given twice a week from October through May. (Solaria using Eveready Sunshine carbon arcs, General Electric Type S1 lamps, and Cooper-Hewitt mercury arcs in corex D glass tubes and

accommodating 150 students per hour have been installed.)

2. Since we found that the alkaline reserve in a group of "cold-susceptibles" was in many cases lower than that in a group of "cold-immunes," we have been issuing to the "cold-susceptibles" joining the class one-ounce packages of a powder composed of equal parts of sodium bicarbonate and magnesium carbonate flavored with oil of peppermint, with the directions to "take one teaspoonful in a glass of water twice a day for three days whenever the nose runs or the throat feels sore."

3. A sheet of specific instructions concerning diet, alkalization, ventilation, sleep and ultra-violet irradiation is given each member of the class.

4. In those persons whose colds continue to occur in spite of the above regimen (approximately 5%), a careful study of the nose, throat and sinuses is made. Where a chronic sinusitis exists with the nose structurally normal, an autogenous vaccine is made up and given subcutaneously in 1 cc doses once a week through the year. Where sinuses, nose and throat seem normal, a mixed stock catarrhal vaccine is given in 1 cc doses once a week for a varying period. Where nasal obstruction, empyema of sinuses, or chronic infection of tonsils demand it, operation is advised. Each week during the period of treatment, each member of the cold-prevention class fills out a slip printed as follows:

Date.....

Name

Have you had a cold during the past week?

Yes.....

No.....

If "yes" was it mild?.....

Severe?.....

Each week also a control group of similar "cold-susceptibles," untreated and simply under observation in a weekly hygiene class, fills out a similar slip.

THE RESULTS

From the group of 1400 students estimated to be "cold-susceptible" approximately 200 have joined our "cold prevention" class each year. Approximately one-half of these have been regular enough in their attendance at the class to make their records usable in checking results statistically.

The results in the last two years have been as follows:

	Treated group	Control group
1929-1930 Number of colds apiece	2.16	4.41
1930-1931 Number of colds apiece	2.38	4.12
Average per cent reduction for 2 years	46.7%	
Reduction from an average of 4.26 to 2.27 colds apiece per year.		

CONCLUSIONS

1. At the present time, so far as we can ascertain, there is no panacea for the prevention of colds.

2. Since epidemics of colds in student groups appear to be limited largely to the "cold-susceptible" 23%, efforts directed at that particular group should be the most fruitful.

3. The interest of at least 1/7th of these "cold-susceptible" students in the prevention of their colds can be aroused and sustained by offering "cold prevention" classes.

4. If in these classes, matters of diet, alkalization, ventilation, toning up of the skin vessels by ultra-violet or sunlight, and in special cases the correction of nose and throat abnormalities and the use of vaccines are stressed, an average reduction of approximately 46% in the incidence of colds can be prophesied.

5. Which of these various factors is the most important is a question, but the ultra-violet or sunlight bathing is, undoubtedly an essential factor in arousing and sustaining the interest of the patient in the project.

6. A definite advantage of this plan of attack is that it furnishes a means of applying a number of the principles that are now available for the prevention of colds. As new principles are evolved they can be promptly put to work and in the group where they should do the most good.

THE INDEX

The annual index is an essential part of the NEW YORK STATE JOURNAL OF MEDICINE for the policy of the Committee on Publication is that every item in the Journal shall be of permanent value, and therefore shall be included in an index.

The making of the index involves two irreconcilable conditions. The index cannot be

made until the last Journal of the year is made up and that Journal cannot be made up until the space to be occupied by the index is determined. It may therefore happen, as in this issue of the Journal, that a blank page is left at the end of the index. This page (numbered 1458) is utilized for editorial comments on the scope and value of the index.

THE MEDICAL ARMY

The medical profession is an army whose object is to combat death and sickness and physical weakness, and to secure the blessings of health and vigor for all the people.

The officers of the army are the research workers,—men of vision and skill who discover the secrets of the enemy, the disposition of its forces, and its manner of destruction.

The officers also plan the lines of campaign against the enemies of health, and take the lead in the first line of the attack often to their own injury and death.

The rank and file of the regular army of health is composed of family physicians in private practice. While they conform to the standards and orders of procedures laid down by their leaders, yet, like good soldiers, they use their own judgment in regard to the details of applying the principles. The great problem of medical practice, as in the regular army of the United States, is to combine independence of action of the individual with conformity to the high standards of the leaders.

The medical profession of the United States composes an army whose number is about the same as that of the regular army of the nation, and whose devotion to the cause of health equals the loyalty of the soldier in national defense.

The soldier is called to action only in an emergency, such as the Mississippi flood; or in a time of peril, such as the presence of a destructive mob or an armed invasion. Speech-making agitators arouse enmity and illwill, and then call on the soldiers to bring back peace and concord. But when goodwill is re-established, the people ignore the plea of the soldier to make preparations for dealing with or preventing future emergencies.

The medical army is prepared to cope with the forces of ill health which invade the country from other lands, and receives the intensive support of the people when it is engaged in resisting the entrance of cholera or plague into the country. But in the presence of internal apathy and unseen danger, the medical army is wellnigh as helpless as the regular army in the presence of propagandists of anarchy. However, the weapon of popular education is valuable to both the soldier and the physician. In fact, the physician is often blamed for not using that weapon more extensively in a finance warfare against ill health.

The development of the modern army of the United States has been a gradual evolution growing out of the application of scientific facts newly discovered. It is only within the last decade that the medical profession has been able to incarnate the public health ideals of medical leaders and express their collective aspirations toward a universal health service. It is also within this same decade that public officials and the people have

been willing to give heed to the pleas of physicians for the support of their public health programs. The evidence of great progress in the development of health service by physicians is found in the descriptions of the activities of medical societies of counties, States and the nation recorded in the *NEW YORK STATE JOURNAL OF MEDICINE*, and the organs of other state medical societies.

While physicians have developed their work quietly and unobtrusively, two other groups have organized themselves for defense against ill health with the use of extensive publicity. The first group in the order of time as well as importance is composed of officials of departments of health, with whom the medical profession is cooperating with increasing harmony.

The second group of health workers is composed of voluntary health organizations, many of which are financed by great endowments, and have made studies, both intensive and extensive, into the medical needs of the people and the provision for supplying these needs. Three groups have reported having studied the last year:

1. The Governor's Health Commission of the State of New York, which recommends great extensions of public health work by the governments of the several counties and the State.

2. The Committee on the Costs of Medical Care whose majority report recommends group insurance as a means for securing medical service.

3. The Committee on Medical Education which makes recommendations for training medical students to give the forms of medical service demanded by modern economic conditions.

In all the extensive publicity and discussion which the reports of the lay groups are inspiring, two fundamental facts remain unchanged:

1. The proposed medical service must be rendered by an individual physician making contact with each individual case.

2. Every patient will demand that the privacy of one's own person and one's communications with the physician shall be maintained to the utmost degree.

It is good psychology, as well as conformity to American customs, that the individuality of the doctor and the patient shall be maintained no matter what official form the economics and finances of the professional relations may be.

The defects disclosed by the reports of the Governor's Health Commission and the Committee on the Costs of Medical Care are those relating to the public rather than the medical profession; and the remedies proposed consist largely of group actions by the people. Physicians may be trusted to analyze the reports in the light of the professional experience of the family doctor, and to adapt their own services to the needs of all the people.

MEDICAL PROGRESS

Rickets: A New Treatment.—In a preliminary report Charles James Bloom relates his experience in the treatment of rickets with secondary calcium phosphate (dicalfos) in the place of cod-liver oil or vitamin D. His published research studies on the utilization of this salt in experimental rickets in the Albino rat and the results in 31 cases described in detail in this paper demonstrate the curative value of dicalcium phosphate in rickets. The best results were obtained when this salt was added to, in the order named, (a) a mixture of unsweetened milk and a stock solution containing karo syrup and lactic acid; (b) condensed milk formulae; (c) dried milk mixtures; (d) dilutions of cows' milk. The dosage of dicalcium phosphate was usually 10 or 15 grains daily, though in some instances 20, 30 and even 40 grains were given. The preparation never caused vomiting or constipation. The reason why this salt should accomplish the results obtained are: (1) The calcium and phosphorous content of cows' milk is not available for complete metabolism due, perhaps, to the large amount of both of these elements which is encased in the curd. (2) It is more than likely that the pH of the gastric content plays a part in rickets, and that an increase in the acidity may facilitate the absorption of the calcium and phosphorus. (3) The type of milk must play a part in the utilization of dicalcium phosphate, since better results were obtained with mixtures (a) and (b). The addition of this salt may supply an excess of both calcium and phosphorus and thereby replace the calcium and phosphorus contained in the curd, which apparently is not available. Since the children in the series here reported were not given either cod-liver oil or vitamin D, it is believed that the addition of dicalcium phosphate to the diet can prevent and cure rickets.—*Southern Medical Journal*, November, 1932, xxv, 11.

The Complications of the Common Cold.—A. Lowndes Yates, writing in the *Practitioner*, November, 1932, cxxix, 773, states that the common cold is devoid of complications except in the following circumstances: (1) When the discharges are confined within a sinus or within the middle ear by reason of the swelling of the mucosa which interferes with drainage. (2) When there is a secondary infection from contact with a person carrying in his nose micro-organisms which have learned to resist the natural destructive powers of the nasal mucus. (3) When the mucus in the nose is diluted by nasal douching or by bathing, thus interfering with its bactericidal function. (4) When the common cold affects a

person who is in poor health. As the complications of a common cold arise with great rapidity and are often serious it is important to recognize the symptoms which are their precursors. These symptoms are pain, alteration in the character of the discharge, malaise, and fever. If pain comes on two days after a person has caught cold, he is suffering either from an acute and dangerous infective rhinitis implanted on a common cold, or from a chronic inflammation in a paranasal sinus, his immunity having been lowered by the cold. When the nasal sinuses are involved the diagnosis is made by the presence of pain. Relief is afforded in the early stages by cocaineization of the nose, thus effecting drainage, and in the later stages by washing out the sinuses with liquid paraffin. If the complication is an acute otitis media, it is treated by efficient myringotomy, not merely paracentesis. The sooner the operation is performed the quicker the recovery. Laryngeal and bronchial complications are treated by sprays of liquid paraffin which aid the cilia in conveying the excess of mucus through the trachea and larynx. If complications are impending, microscopic examination of the discharge will reveal lymphocytes and polymorphonuclear cells. Such an examination is useful in determining whether or not a case of complications should be treated surgically. Immunity must be established before the tissues can withstand the trauma of an operation. In every case of common cold in which the ear has become involved, the hearing should be carefully tested with tuning forks to determine the presence of subacute otitis media. This mild inflammation is important because it causes thickening in the region of the round and oval windows, which, if neglected, may result in the course of several years in irremediable loss of hearing.

A Study of Renal Infarction.—J. Dellinger Barney reports the case of a woman, aged 31, who gave a history of three miscarriages, and who stated that on each occasion there had been albumin in the urine. Phlebitis of both legs occurred after the last confinement and had recurred from time to time ever since. After considerable study a diagnosis of perinephritic abscess was decided upon, and an operation was performed. No pus was found. The kidney was partially decapsulated, exposing a dull red, dead-looking cortex. There was no bleeding. A biopsy specimen showed complete degeneration of the tubules and glomeruli. As the patient did not progress

favorably a nephrectomy was performed. After several days of stormy convalescence bronchopneumonia and empyema developed and the patient died ten days after the operation. The pathological examination showed infarction of the kidney, with complete degeneration of all its tubules and glomeruli. Autopsy revealed thrombosis of the vessels of both legs and complete occlusion of the right ovarian and right renal veins. The mistaken diagnosis in this case led the author to review the literature of kidney infarction and to study the records of 146 autopsy cases. From this study he drew the following conclusions: (1) Renal infarction occurs in either sex, and at almost any age, usually between the thirtieth and fiftieth years. (2) There may be no clinical symptoms whatever. Such symptoms as are noted may be due quite as much to the condition causing the infarction as to the infarction itself. In total infarction of one or both kidneys, pain and tenderness of definite severity are to be expected. (3) Endocarditis, acute or chronic, generally with extensive arteriosclerosis, is to be looked for in the majority of these cases. Occasionally, infarcts result from chronic or acute sepsis in the presence of a normal heart. (4) Prognosis depends largely upon the underlying condition, i.e., endocarditis, arteriosclerosis, and sepsis. Usually the patient has a poor chance of recovery. (5) No definite rule can be laid down as to treatment. The infarct which causes no symptoms will generally take care of itself. Much more important is the treatment of those conditions which favor the formation of infarcts. These, however, are generally chronic and incurable.—*New England Journal of Medicine*, November 10, 1932, ccvii, 19.

The Treatment of Fractures. — N. Ross Smith outlines certain advances in the treatment of fractures which are not applied as generally as they should be. Until shock has passed off, little but first dressing and immobilization should be attempted. Reduction in some fractures may be done immediately by the hands. Recently the Böhler method of traction for immediate reduction by means of the screw has been introduced. This requires special apparatus and skill. Complete reduction is essential to prevent subsequent osteoarthritis. In the application of continuous immobilization after reduction, great advances have been made. Wooden and nonplastic splints have been discarded. For fractures of the upper limb the Thomas arm splint, the sling, and plaster of Paris suffice. For the lower limb the Thomas and Hogdem splints are now used, not as originally, but merely as a means of supporting the limb, while traction is transmitted through them, or independently

of them, by means of an overhead frame. To avoid the need of a frame, splints such as the Hey Groves' cradle and Böhler's modification of Braun's lower leg splint are employed. Plaster of Paris is chiefly used for fractures of the spine, the joints, and certain fractures of the shafts of long bones. Fixed traction has been largely given up except for first aid and transport, in favor of mobile traction — the old weight and pulley method. Formerly this was applied by means of skin traction, the grip on the limb being taken by means of adhesive material. Skeletal traction is now used. This implies application of traction to the distal fragment by tongs or calipers which grip the bone, or by pins, nails, or taut wire driven through the bone. Skeletal traction leaves the limb free for inspection, massage, or treatment of the wound. The time allowed for fixation was formerly too short; six months is now thought desirable, but this does not necessarily imply long recumbency. It is also recognized now that for some months after apparent consolidation of the fracture protection against deformity should be provided by apparatus. If the means of fixation allows, massage at the site of the fracture and movements of the neighboring joints are employed; otherwise they are deferred. Passive movements are no longer permitted; movements should always be voluntary. If joints are involved early movements may be positively harmful. The problem of operative *versus* non-operative treatment is also more clear than formerly. A minority of fractures are best treated by operation. This, in most cases, consists merely in reduction of the fragments into accurate apposition, followed by fixation by external means. There is a general feeling against the use of plates and other metallic substances, in favor of less irritating or absorbable materials, such as beef-bone grafts, ivory, catgut, and silk. An important advance is the routine use of the x-rays in the diagnostic examination, with one or more examinations during the period of fixation. Another innovation is the use of local anesthesia in the reduction of fractures; this has many advantages over general anesthesia.—*Practitioner*, November, 1932, cxxix, 773.

Orthopedic Treatment of Acute and Subacute Poliomyelitis.—Alan H. Todd notes that the standard textbooks say little or nothing about the treatment of infantile paralysis in the acute stage, the authors contenting themselves with remarking that the treatment consists in massage, electrical stimulation, and the use of appropriate braces, but they give no indication as to the stage at which these treatments should be used or their relative values. The writer says it is therefore vital to state as emphatically as possible that in the

acute stage of poliomyelitis complete rest and relaxation of the affected muscles meet the one and only indication so far as the orthopedic treatment is concerned. A paralyzed muscle that is stretched, he says, will not recover, even though it be given electricity and massage. On the other hand, paralyzed muscles frequently recover when given relaxation and nothing else. At the beginning it is not always easy to know which muscles to relax, but when definite loss of power has appeared the proper line of treatment is obvious. It is sometimes possible, even before definite inability to make voluntary movements has appeared, to feel a flabbiness of the muscles, or of a group of muscles, foretelling the seat of the imminent paralysis. The indication is then to secure relaxation of that muscular group. As a general rule the paralysis is much more extensive in the early stages of the attack than it is eventually. Therefore when called upon to treat a patient in the early stage, when no definite signs have appeared and several limbs perhaps are paralyzed, the best course is to relax those muscles which (1) matter most from the point of view of ultimate function, and (2) are known from practical experience to be most liable to attack. In the case of the lower limbs the quadriceps and the extensor group on the front of the leg are the most important muscles and are also the group most generally affected. The indication is obvious: the foot must be supported at a right angle with the leg and the knee must be kept straight. If, however, the calf is affected more than the extensor group, the reverse treatment would be necessary, that is to say, the foot would have to be placed in plantar flexion. If the abductors of the hips seem to be at all weak, or if both abductor and adductor groups be paralyzed and one does not yet know which group will ultimately prove to be the more severely affected, the lower limbs should be widely separated to relax the glutei. It is impossible to lay down any fixed rules with regard to the position to be enjoined in a case of paralysis of the trunk muscles. It is fundamental, however, that any paralysis or suspected paralysis of the trunk muscles necessitates complete and prolonged recumbency. Three months' complete rest and relaxation are the very minimum, and in most cases a year or even more of complete recumbency will be necessary. In the upper extremity the deltoid muscle is often severely paralyzed, but that is because it is inadequately treated. It is so often affected that it might almost be laid down as a standard rule that the arms should be fixed in elevation to a right angle and maintained there for some length of time. How long rest and relaxation of a paralyzed muscle should be maintained is difficult to say, but as a general rule it should be a month at the least. Manual massage, to stimulate the circulation, should be the first method of adjuvant treatment, but electrical stimulation should be resorted to with extreme caution in the earlier

stages of the disease. *The Lancet*, November 12, 1932, ccxxiii, 5698.

The Nutritive and Medicinal Properties of Glucose and Honey.—In the course of studies, pursued for a number of years, of the ideas and practices of Hippocrates, Arnold Sack became impressed with the large amount of glucose and levulose present in genuine bees' honey, the use of which was strongly recommended by the medical school of Cos. Recent analyses of honey in Europe and America give as its constituents approximately 34 per cent glucose, 40 per cent levulose, and only 0.40 to 6 per cent cane sugar, with 17 to 24.50 per cent of water. An average of 70 per cent of invert sugar is not to be despised. Other substances present in too small amounts for percentage are wax, dextrin, and gummy substances; pollen grains, organic acids, such as malic and acetic, and possibly formic acid; mineral substances, such as manganese, magnesium, phosphorus, calcium, iodine, iron, etc.; derivatives of chlorophyll pigment, such as carotin, xanthophyll, and also a black pigment of unknown composition; and, in addition, enzymes, vitamins, and aromatic substances, the latter including rosin, turpentine, volatile oils, certain perfumes, aldehyde, the higher alcohols, mannitol, dulcitol, etc. There is no possibility of any laboratory substitute being invented that can satisfactorily replace natural honey. It possesses nutritive and medicinal properties all its own, that cannot be counterfeited. Sack brought about a clinical cure of a case of cholecystitis and pyelitis of 25 years' standing, with bacteriuria and pyuria, the urine being extremely foul, by giving honey in doses of, at first, 100 gm., and later, 50 gm., daily. Honey is one of the few foods—perhaps the only one besides glucose—that is assimilated without rests or dregs left in the intestinal canal. The trace of cane sugar is converted into glucose by the honey enzyme. The common view that enzymes cannot survive the destruction to which they are subjected in the stomach by the action of hydrochloric acid is questionable in its application to the honey enzyme, since Holtz found the alkalizing effect of concentrated glucose solution so powerful that it could be used in the treatment of gastric ulcer. That author also used it in many diseases of the liver, for the destruction of fat and for the treatment of diabetes, etc. A diuretic effect has been noted in honey, and Sack has used it effectively in this capacity. Applied externally upon septic wounds it has been observed to have a bactericidal effect and also to promote granulation.—*Münchener medizinische Wochenschrift*, October 14, 1932.

The Treatment of Laryngeal Tuberculosis.—In addition to the inhalation of such powders as anesthesin and orthoform, the application of the galvanocautery and alcohol injec-

tion into the superior laryngeal nerve, James Dundas-Grant calls attention to two practical points in the treatment of laryngeal tuberculosis. The patient may suffer from a painful "burning" stiffness of the pharynx caused by the drying and inspissation of mucus on the back wall, experienced chiefly on awaking. This can be removed by gargling with a little bicarbonate of soda in water, warm if possible. Such a solution may be put in a thermos flask at night so as to be ready for use when the patient awakens. This condition is often overlooked while deeper sources of pain are sought for. The second point is that pain is one of the strongest indications for the use of the galvanocautery, and by no means a contraindication, as has been suggested. The typical tearing pain is almost invariably caused by a spot of ulceration. If the spot can be localized the application of a fine galvanocautery point destroys the exposed nerve endings and removes the pain. A laryngeal probe coated with cotton-wool should be applied to various parts of the larynx until the patient makes known that the pain-producing spot has been touched. After cocainization of the part the fine point of the galvanocautery should be applied to the spot, and in the absence of other sensitive spots pain is usually removed. Those who attempt to practise such manipulations should always hold the laryngeal mirror in the left hand, leaving the right one free for the handling of instruments.—*The Lancet*, November 5, 1932, ccxxiii, 5697.

The Prevention of Renal Complications Following Scarlet Fever.—As the use of scarlet fever antitoxin has not had any appreciable effect in reducing renal complications, B. A. Peters attempted to control the after-effects of diphtheria and scarlet fever by the following method. He administered an alkaline mixture containing sodium bicarbonate 30 grains, potassium bicarbonate 5 grains, calcium carbonate $7\frac{1}{2}$ grains, in 1 ounce of metholated peppermint. This was given in ounce doses until the urine was alkaline to litmus. In addition, weak tincture of iodine was administered in minim doses for each year of age up to a maximum of 20 minims, in 2 ounces of milk, every four hours; and also 2 to 4 grains of fresh thyroid gland daily for fourteen days after admission. The large doses of iodine were well borne and did not cause gastric irritation. In order to assess the value of this method Peters compared the incidence of renal complications in a series of 1,050 control cases with those in 930 cases in which the medication was employed. In the control series the total number of renal complications was 120, or 11.2 per cent, while in the test cases it was 21, or 2.2 per cent. Thus it is

seen that by this method of treatment the incidence of complications was reduced by 80 per cent, and no fatality due to renal affection occurred. The method is simple in application, free from danger and not too obnoxious to the patient.

The author discusses the theory upon which the medication above described is based, namely, the changes which occur in the colloid particles visible in the serum when viewed by a dark ground condenser, as demonstrated by McDonagh. From his observations, which have been confirmed by Peters, it would appear that in toxin-producing diseases, such as diphtheria and scarlet fever, these particles tend to be reduced in number and to form larger aggregates. On recovery with suitable drugs the picture reverts to normal. Whether these phenomena are due to alteration in the state of dispersion of proteins or lipoids, or possibly both, in disease is still undetermined.—*Practitioner*, November, 1932, cxxix, 773.

Radiographic Investigation of Lumbar and Sciatic Pain.—James P. Brailsford, writing in the *British Medical Journal*, November 5, 1932, ii, 3748, reminds us that no symptom or group of symptoms as those known to the lay public under the terms "lumbago" or "sciatica" may be due to such a diversity of causes. In the investigation of cases of lumbar and sciatic pain, antero-posterior and lateral radiographs of the lumbar and sacral spine, pelvis, and hip-joints should always be made. These may give an immediate clue to the cause of the symptoms. The lesion of the skeletal tissues or viscera which gives rise to the pain may be due to (a) congenital or developmental abnormalities; (b) trauma; (c) toxemia; (d) acute or chronic inflammatory conditions; (e) tumors. Congenital or developmental irregularities occur in a large percentage of cases; Brailsford found them in about 25 per cent of his cases. They should not, however, be ascribed as the cause of the symptoms until all other possible lesions have been excluded. In cases of injury to the back or pelvis, radiographs should be taken as soon as possible after the injury and the films kept for reference. It is possible to give some idea of the age of a bone injury from the radiograph, and this may be of great importance before the courts for compensation. Changes indicative of injury may be shown on radiographs taken subsequently which were not present in the first radiographs. Acute lumbar and sciatic pain is most frequently associated with toxemia from some focus of septic absorption, such as teeth, colon, genito-urinary system, appendix, gall-bladder, sinuses. Radiographs will often arouse suspicion of septic absorption from teeth, though local symptoms may be absent.

LEGAL

DRUGGIST'S LIABILITY IN FILLING PHYSICIAN'S PRESCRIPTION

By LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York.

Recently an interesting case was carried to the highest court of one of the nearby states in which the question involved was the liability of a druggist in compounding a prescription. An action was brought against a drugstore to recover damages for injuries alleged to have resulted from taking three capsules containing strychnine which were compounded in the drugstore of the defendant, upon the prescription of a regularly licensed physician.

The facts as developed from the testimony at the trial were quite clear. The plaintiff caused to be filled at the drugstore a prescription calling for certain capsules, each containing $\frac{1}{4}$ grain of strychnine and other ingredients. The box in which the said medicine was put up was not labeled "poison" or "strychnine." Following the instructions of the physician the plaintiff took three of the capsules at intervals of two hours. After the third had been taken the "plaintiff became stiff and could not get up from his chair or sit down." There was medical testimony to the effect that he thereafter sustained a weakened and nervous condition attributable to an overdose of strychnine. The testimony of the experts for the plaintiff was to the effect that ordinarily a dose of strychnine is no greater than $\frac{1}{30}$ of a grain, and that as low as $\frac{1}{20}$ of a grain has been known to be fatal. However, the same witnesses testified that ordinarily $\frac{1}{2}$ grains was considered a fatal dose, but that there had been a reported case where 15 grains was not fatal. It was also testified that the effects of strychnine are usually eliminated from the body in about four hours, and that the amount to be given as a safe dose varies greatly according to the individual, and his condition at the time.

No claim was made by the plaintiff that the prescription was inaccurately filled. The contention was, however, that the druggist should have refused to fill the doctor's prescription as calling for too large a dose. In addition it was contended that the druggist having failed to comply with the law with reference to the labelling of poison was by reason of that fact alone liable for any damage that might follow.

The case was sent to the jury and a verdict for the plaintiff was rendered, and from the judgment entered thereon an appeal was taken.

The Appellate Court reviewed the case and concluded that the testimony was such as to require the trial court to grant the defendant druggist's motion for a directed verdict.

The court considered and disposed of very briefly the contention that there had been a violation of the law by the druggist. The court stated that an examination of the testimony failed to show that the failure to mark the prescription as "poison" or "strychnine" had any bearing on the damages sustained. It was ruled that when there is a violation of a statute proved and damages follow, there can be no recovery unless it be also shown that the violation of the statute was the proximate cause of the injury complained of.

The court then considered the circumstances in the case generally and ruled that the dose called for in the prescription was not such an unusual one as to make the druggist liable for not refusing to fill the prescription. The opinion of reversal stated in part:

"The question here is under what circumstances should a pharmacist set up his judgment against that of a licensed physician?

"No witness has undertaken to say that ordinary care would have required any pharmacist to decline to fill the prescription in this case; and ordinary care, in view of the nature of the business, is the test. Of course, if a druggist is negligent in filling a prescription, he cannot escape liability because the doctor who wrote the prescription is also liable.

"But it does not follow because a physician in a given case is liable, that the druggist who filled the prescription is also liable. It would be a dangerous principle to establish that a druggist cannot safely fill a prescription merely because it is out of the ordinary. If that were done, many patients might die from being denied unusual remedies in extreme cases.

"Of course this does not mean that pharmacists can safely fill prescriptions calling for doses that are obviously fatal; or that where the doses prescribed appear to be unusual the prescription can be safely filled without inquiry of the physician to make sure there has been no error.

"There is no evidence that this precaution was not taken in the present case, but, even if it was not, that would be immaterial here, because the result of such inquiry would have

been to confirm the prescription, as the physician who wrote it testified that it was his usual prescription in such cases."

The rule enunciated in said case with respect to the liability of a druggist or pharmacist is a reasonable one and seems to be completely in accord with the law of this State. The similarity of this doctrine to the law of malpractice is quite apparent. When a druggist undertakes to fill a prescription he is legally assumed to possess the ordinary skill of a druggist and it is required that he exercise due and proper care in putting up the required medicine, the degree of care required being proportionate to the gravity of the injury that would result necessarily from a want of care. The druggist is not an insurer, and a recovery in a damage suit against him must be based upon proof of negligence. As was stated by the highest court in this State:

"The basis of the action is the sale of a poison to a person who called for a harmless drug; and the law is well settled that in such a case evidence of negligence is necessary in order to make out a cause of action. Mere proof of the mistake is not enough in and of itself to charge the vendor with liability."

The court in said opinion said:

"The negligence which must be established to render a druggist liable in such a case as this is measured by his duty; and while this is only to exercise ordinary care, the phrase ordinary care in reference to the business of a druggist must be held to signify 'the highest practicable degree of prudence, thoughtfulness and vigilance, and the most exact and reliable safeguards consistent with the reasonable conduct of the business in order that human life may not constantly be exposed to the danger flowing from the substitution of deadly poisons for harmless medicines.'"

Some years before this same Court was confronted with an action arising out of a person having received a dose of calomel where the

drug intended to be dispensed was quinine. In its opinion the court stated:

"The rule of liability applicable to a druggist in cases of this character is the same as that which governs the liability of professional persons whose work requires special knowledge or skill, and a person is not legally responsible for any unintentional consequential injury resulting from a lawful act when the failure to exercise due and proper care cannot be imputed to him, and the burden of proving such lack of care, when the act is lawful, is upon the plaintiff."

The New York Court of Appeals quoted with approval from the opinion of a famous Michigan Judge as follows:

"The question is whether the delivery at a drug store of a deleterious drug to one who calls for one that is harmless, and a damage resulting therefrom, of themselves, give a right of action even though there may have been no intentional wrong and the jury may believe there is no negligence. That such an error might occur without fault on the part of the druggist or his clerk, is readily supposable. He might have bought his drugs from a reputable dealer, in whose warehouse they have been tampered with for the purpose of mischief. It is easy to suggest accidents after they come to his own possession, or wrongs by others, of which he would be ignorant and against which a high degree of care would not give a perfect protection. But how misfortune occurs is unimportant if, under all circumstances, the fact of occurrence is attributable to him as a legal fault. The case is one in which a high degree of care may justly be required. . . . It is proper and reasonable that the care required shall be proportionate to the danger involved. But we do not find that the authorities have gone so far as to dispense with actual negligence as a necessary element in the liability when a mistake has occurred."

NEEDLE BREAKING DURING ADMINISTRATION OF TOXIN-ANTITOXIN

A certain City had undertaken to hold a series of free diphtheria toxin-anti-toxin clinics at its public schools and certain physicians were appointed to administer the serum. The clinics were crowded with applicants for the inoculation, and the health officer found it necessary to call upon the defendant doctor to assist in administering the injections. The children were brought into a room and directed to stand in two lines, and after having had their arms sterilized by a nurse they received the inoculation from the defendant and another doctor. There was con-

siderable confusion and congestion in the room. An eight-year-old boy was being inoculated by the defendant when the mother of one of the children who was standing nearby suddenly bumped into the doctor, shoving the doctor's arm and causing the needle to break off. The doctor noticed that the point was not protruding from the child's arm so that it was impossible for him to pull out the fragment of needle immediately. He, therefore, requested the mother to take the child to one side and wait until the rush of patients was over when he would see about

removing the needle. The child and his mother waited for some time for the rush of patients to clear up and then told the doctor that they could not wait any longer. The doctor gave them his card and told them to come to his office during his office hours, stating to the woman that at his office he would have available suitable instruments to attempt to remove the needle.

Sometime later in the day the child was brought to the doctor's office and an x-ray was taken of his arm. The doctor attempted to remove the needle under a local anaesthesia but was unable to do so. He then took the child to an x-ray laboratory and attempted to remove the needle under a fluoroscope, which attempt was likewise unsuccessful. The doctor then communicated with the City Health Officer and notified him of the occurrence and asked what further should be done. The Health Officer advised the doctor that he should arrange to have the child report at a certain hospital the next morning and he (the Health Officer) would try to remove the needle. Further attempts were made at the said hospital, both by the Health Officer and the defendant doctor, to remove the needle which were unsuccessful.

The mother was informed of the difficulty that had been encountered with the needle and she was advised that the needle probably would do no harm in the boy's arm, but she was told that if she wanted some other doctor to try and remove the needle, arrangements would be made for such an attempt. She requested a further attempt be made to remove the needle and the next day another surgeon put the child under a general anaesthesia and with the use of x-rays and the fluoroscope the said surgeon probed further

for the needle, but this attempt was also unsuccessful. Therefore, no other attempts were made to remove the foreign body. The child's arm was dressed in the hospital and at his home by the defendant doctor. The wound healed promptly without any infection.

The next the doctor heard of the case was that he indirectly received word that the child's mother was going to sue the City for negligence in not providing proper facilities for the inoculation of school children and in permitting dangerously large crowds in the rooms where the injections were being made.

An action was brought against the defendant doctor by the child's father, as his guardian ad litem, charging that the defendant was negligent in permitting the needle to break in the child's arm and in failing to remove the fragment from the said arm.

The case was tried before a Judge and Jury and upon the trial the testimony of the witnesses on behalf of the plaintiff emphasized the fact that after the needle had broken in the child's arm instead of immediately endeavoring to remove the broken needle the defendant caused the child to wait until he had treated a number of other children. At the close of the testimony introduced on behalf of the plaintiff a motion was made by the counsel for the doctor for a dismissal of the complaint on the ground that the cause of action had not been proved. This motion was granted by the Trial Judge.

An appeal was taken to the Appellate Division by the attorneys for the plaintiff. The Appellate Court, however, affirmed the decision of the Trial Judge and the matter was thereby finally terminated in favor of the doctor.

INJURIES RECEIVED BY HEAT LAMP BURSTING

The defendant in this case was a doctor whose practice included a considerable amount of industrial surgery which was handled by him at a clinic conducted for the purpose of treating compensation cases.

A certain workman claimed to have been injured by being struck on the back by a falling object. His employer sent him to the clinic where the doctor examined him. His complaints were of soreness in the back but the doctor was unable to find any objective symptoms. After an examination the doctor determined to administer to the patient a heat treatment by exposure to a so-called Burdick lamp. The doctor adjusted the lamp at a point of about fifteen inches above the patient's back and gave the patient instructions to notify him if it became too warm. After the lamp had been turned on for about five minutes the doctor heard a loud explosion and

looking at the patient saw that the bulb of the lamp, which was of 1,500 watt intensity, had burst into small particles and that the patient's back had been scratched in numerous places by the hot flying glass.

The doctor cleaned up the condition and applied unguentine and bandages and sent the patient home.

The patient never returned for further treatment, but instituted suit against the doctor and the insurance carrier, charging the doctor with negligence in his treatment of the patient. The doctor's answer set up the defense that the injuries for which the patient was suing the doctor were included in the claim which the plaintiff had pending for workmen's compensation. The attorney for the plaintiff, after discussing the matter with your Society's Counsel, agreed to discontinue the case against the doctor.

NEWS NOTES

COMMITTEE ON THE COSTS OF MEDICAL CARE

An all-day meeting of the National Committee on the Costs of Medical Care of the American People was held on Tuesday, November 29, 1932, in the building of the New York Academy of Medicine. The object of the meeting was the formal presentation of the Committee's report and a discussion of the general attitude of the public toward the recommendations. There were present over two hundred persons—members of the Committee and their guests consisting of practising physicians, public health officers and teachers, social workers, and investigators—who had come from all over the United States to meet the distinguished leaders in medical administration and appraise their personalities and arguments.

Advance copies of the findings, plans, and recommendations of the Committee had been distributed to members of the Committee and invited guests several days in advance of the meeting, in the form of a printed volume of 214 pages. Even the principal addresses that were given at the meeting had been mimeographed and copies were available for the press and officials of medical societies. The meeting was therefore eminently satisfactory from the point of view of those whose duty it was to report the meeting and inform the public in regard to the work of the Committee.

The program consisted of sessions in the morning, afternoon, and evening, with a social luncheon at noon and a dinner at early candlelight, both served in the Academy building. All the events passed off in a pleasing way, and to the satisfaction of the Committee members and their guests.

The Committee on the Costs of Medical Care has been in existence for five years. It was the development of a series of informal conferences and consultations at meetings of the American Public Health Association and the American Medical Association, which finally resulted in a voluntary organization of forty-eight leaders representing the following five groups of persons:

1. Private practice of medicine and dentistry, with 17 members. New York is represented in this group by Dr. N. B. Van Etten, Past President of the Medical Society of the State of New York, and Dr. William Darrach.

2. Institutions and special interests, with 10 members including nurses, pharmacists, and administrators, and also Dr. Olin West, Secretary of the American Medical Association.

3. Public Health, with 4 health officers and 2 statisticians and teachers.

4. Social sciences, with 5 doctors of philosophy.

5. The Public, with 9 business men and public health workers, including the chairman of the Committee, Ray Lyman Wilbur, M.D., former president of the American Medical Association, and now Secretary of the Interior in President Hoover's Cabinet.

The Committee is primarily a fact-finding organization, whose purpose is to secure data regarding all phases of health service to the people, including the practice of medicine and dentistry, hospitalization, pharmacy, cults, self-medication, and quackery. Its work of investigation was financed principally by eight organized endowments which are listed in the report volume as follows:

- The Carnegie Corporation
- The Josiah Macy, Jr., Foundation
- The Milbank Memorial Fund
- The New York Foundation
- The Rockefeller Foundation
- The Julius Rosenwald Fund
- The Russell Sage Foundation
- The Twentieth Century Fund

The cost of the investigations was about one and one-half millions of dollars.

The report also gives credit to the following organizations concerned with public health, for assistance in the studies and the compilation of the statistics:

- The American Medical Association
- The American Dental Association
- The Metropolitan Life Insurance Company
- The National Bureau of Economic Research
- The National Tuberculosis Association
- The United States Public Health Service
- Departments of Health of the States
- Visiting Nurses Association

The facts and statistics collected by the workers employed by the committee were published from time to time in twenty-five volumes ranging in size from 54 pages to 340, with an average of 183 pages per volume. These studies are sold at a price of from 25 cents to a dollar and a half each. Three more volumes—perhaps the most important of all—are in preparation on the following subjects:

- The ability to pay for medical care.

- The incidence and costs of illness in representative families.

The costs of medical care, including the economic aspects of the prevention and care of illness.

The official report of the Committee forms a volume of 214 pages, and was formally released at the meeting on November 29. The report first deals with the facts disclosed by the investigators and devotes 102 pages to their findings. These pages summarize the facts which are set forth in detail in the individual publications of the Committee. They constitute the broadest and most reliable study of the problem of sickness and ill-health that has ever been made; and its facts are generally accepted as accurate and truthful.

The Committee devotes pages 103 to 150 to recommendations for future action. It analyzes the data as a physician would study the evidence disclosed by the history and the physical examinations of his patient; and on the basis of its analysis, it makes a diagnosis of *neglected opportunities* by both the medical profession and the people.

The report then prescribes a line of treatment for the patient—the public—advising group action by the people to secure an organized medical service by means of health insurance.

Pages 151 to 183 contain a minority report signed by Dr. N. B. Van Etten and eight other members, seven of whom are practising physicians, and one, Dr. Olin West, is secretary of the American Medical Association. This report tacitly accepts the facts disclosed by the investigation, but changes the diagnosis to that of *opportunities for development*, referring to the great advances that have already been made by practising physicians during the last decade in bringing all forms of medical service within the reach of all classes of people.

The treatment suggested by the minority is the active development of measures which

medical groups have already tried and adapted to public needs in favorable localities. The minority report emphasizes the belief that physicians will evolve their practice into a form which will retain the present general plan of practice, with additions and modifications to suit the progress in medical research, and the education and economic condition of the people.

Speakers in the afternoon session at the Academy on November 29 explained the contrasting recommendations of the two groups with which the Committee is divided. Dr. Van Etten explained the minority report and showed that its plans have been consistently advocated and supported by the medical societies of the counties, States, and nation.

Dr. Van Etten emphatically protested against governmental invasion of the private practice of medicine through any health insurance schemes, and objected to the unsatisfactory administration of our present workmen's compensation laws and to the plans of the majority for large medical centers on the ground of restraint of opportunity for all reputable physicians by oppressive competition and big business technique which would eliminate personality and destroy personal relations by factory methods.

The civic importance of the meeting on November 29 is indicated by the amount of space given to it by the newspapers. Nearly every leading Metropolitan daily gave it a front page position, and some devoted an entire inside page to extensive abstracts from the reports of both the majority and the minority groups, and outlines of their recommendations.

The newspapers have also printed editorial comments on the two reports. It is a noteworthy fact that the editors generally support the retention of the supremacy of the individual family doctor (see page 1438).

COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations met at the Mark Twain Hotel in Elmira at 10 A.M. on November 29th, 1932. Present Drs. Sadlier, Johnson, Fisher, Hambrook, Cunningham, Mitchell, and Ross; also Dr. Lawrence, the Executive Officer, and Dr. Farmer, Chairman of the Committee on Public Health and Medical Education.

Dr. Fisher, the Sub-Committee on the physician's relation to the administration of the Institute for Malignant Diseases in Buffalo, reported that no answers had been received to his letters sent to physicians in Buffalo and that, therefore, he had nothing to report. The

report was received and the committee continued.

The Committee on prison physicians engaging in the private practice of medicine reported that it had had a conference with the Deputy Commissioner of Correction in Albany on November 28th, and that the agreement had been reached that a statement of the facts regarding full time prison physicians engaging in private practice, with a request for the discontinuance of the practice, should be submitted to the Department of Correction for consideration. Dr. Sadlier reported that the Executive Committee of the State Society had au-

thorized the committee to consult the Counsel of the State Society before sending the letter. After discussion it was decided to continue the study of other departments of the state government employing full time physicians and their engaging in the private practice of medicine. This matter was placed in the hands of the same sub-committee, Drs. Ross and Johnson.

The sub-committee on better facilities for physical examination of school children, consisting of the chairmen of the Public Health and Public Relations Committees reported that it had held a conference with the Division of Medical Inspection of the Department of Education, and that Dr. Howe, Chief Medical Examiner, favored the request of the State Society. The conference reached the conclusion that a letter should be drafted by the chairman of the Public Health Committee, the chairman of the Public Relation Committee, Dr. W. A. Howe of the Department of Education, and Dr. Lawrence, Executive Officer, regarding standards of examinations by school physicians and the provision for better facilities for examinations; and that it should be sent to superintendents of schools, boards of education, school physicians, and to officers and committees of the Medical Society of the State; and that it should be published in the *Journal of the State Society*. It was stated that the problem was with the eight thousand one-room schools in the state. The Department of Education agreed with the committee that school examinations should be done as much as possible by the family doctor. It was decided that, before this letter was sent out, it should be submitted to the full committee on Public Relations.

There was a long discussion of the project of giving a talk again this year to the fourth year students in the nine medical schools of the state. There was considerable discussion as to whether the need for this talk arose from the omission of some basic principle of instruction, and if it had, then the lecture should be done as a part of the curriculum. It was the opinion of several that the talk was an effort on the part of the profession of medicine to establish a link between the teaching of medical students and the practice of medicine, and that this could be done only by physicians engaged in the practice of medicine. Dr. William H. Ross, who had given the talks last year, was selected to give these talks again this year.

There was a long discussion of the administration of the Welfare Law. The administration is satisfactory in some of the counties of the state, as in Oneida and Suffolk and Steuben. In some counties there is not much enthusiasm about paying the doctor, and the

welfare service is considered rendered when the patient is hospitalized. In some counties the administration shows no improvement over the old town overseer system. The long discussion on welfare administration brought out many reports and many opinions.

The afternoon session was attended by Drs. Booth, Lewis, Howland, and Cosgrove of Chemung County, and Dr. O'Brien of Steuben County.

Dr. Arthur W. Booth reported for the Medical Society of Chemung as follows:

1. A good working relationship with the governmental and lay health organizations is maintained.

2. The profession is now cooperating with the Health Department in a study of undulant fever and a better controlled milk supply.

3. Broadcasting health activities is being carried on by the physicians.

4. The Board of Supervisors of Chemung County has always been generous in promoting health activities and the profession had no fault to find.

5. The Board of Supervisors is paying bills for the hospitalization of the indigent, and the doctors are voluntarily charging nothing for their services in the hospitals of Elmira, but are paid for their calls to indigent patients in their homes.

6. Physicians are assuming more and more leadership in health activities.

7. X-ray examinations have been made of all high school pupils this year.

8. There is no friction between the profession and other health organizations.

9. No organization starts anything in Chemung County without seeking advice of the medical profession.

10. Doctors are on every health committee of all organizations.

Dr. Howland, the Health Officer of Elmira, reported the following details:

1. Twenty-seven per cent of children are immunized against diphtheria, while it would be thirty-five per cent if the doctors were a little more active.

2. Elmira has a medical center where a dental clinic is maintained three days a week, a venereal clinic two days a week, and there is an orthopedic clinic, a prenatal clinic, a children's clinic, and a mental hygiene clinic. All of these are under the Board of Health. Insanity has diminished since venereal clinics were established.

3. Physicians in Elmira do free work in hospitals because the charters of the hospitals require it.

Dr. Howland further detailed health work in Elmira, discussing such things as the nursing association, and it all indicated that there

was good cooperation between the medical profession and health organizations.

Dr. O'Brien of Steuben County reported as follows:

1. The county is large in area and has a scattered population.

2. The old Health Committee, made up of representatives of the Board of Supervisors, health agencies, fraternal organizations, and the medical profession, did not seem to be functioning well.

3. The health activities were under the Public Relations and the Public Health Committees of the County Society.

4. The greatest need in Steuben County is to create a proper public attitude of mind by educating the public in health matters. The County Society has seven speakers each with seven speeches, covering the county, speaking before clubs, churches, and chambers of commerce, etc., and that it was accomplishing the results expected.

5. Newspaper articles had criticized the work of school physicians. Physicians had prepared other articles for the purpose of putting before the public the viewpoint of the physician without entering into any controversy.

6. The Board of Supervisors had been per-

suaded to maintain their three county laboratories instead of reducing the number to one in the center of the county, but in order to accomplish it, the Public Relations Committee had to educate its own committee and to get its own society to be more active.

7. Clinics are carried on in the county, but they operate with difficulty because of the scattered population.

8. The Public Welfare Law is being administered satisfactorily to the medical profession; doctors are being paid for their work to the indigent in the hospital as well as in the homes, and there is good cooperation between all the lay organizations and official organizations.

9. There is a good system of public nursing under the direction of the Board of Supervisors.

It was brought out by many speakers during the day that medical publicity by speaking before clubs of people such as churches, parent-teacher associations, and luncheon clubs, is a better plan than radio broadcasting. The talks are superior in health education value, especially if the local papers carry the reports.

JAMES E. SADLER, *Chairman*.

W. H. ROSS, *Secretary*.

VETERANS HOSPITALS' ADMINISTRATIONS

Many hundreds of physicians gladly served the country in the World War. Many of these are active participants in the work of organized medicine. These and all of the members of the Medical Society of the State of New York should be interested in the problem of what should be done with the Hospitals of the Veterans Administration. We feel that there has been an excessive dispensing of national bounty in the form of hospitalization. We believe that organized medicine should speak vigorously in opposition to the use of these hospitals in direct and indirect competition with the practicing physicians of the United States many of whom are the same men who volunteered at considerable sacrifice to care for the soldiers during the War.

Our tenets in regard to the use of Administration Hospitals are as follows:

1. Use should be free and generous to all those who were disabled during the War or are suffering from any disability which is of such nature as to make it at all likely that it originated during their term of service.

2. The use of the Veterans Administration Hospitals should be available for all service men whose physical and financial need of such

hospitalization is certified by their attending physician or surgeon or any physician or surgeon who is qualified to so certificate the veteran. Such physician's certificate should be a definite requirement.

Veterans who are self-sustaining and solvent and who suffer from ills not connected with service should not be hospitalized or treated at the expense of the Government any more than they should receive groceries, or clothing, or housing, or coal, or light at the Government's expense. If they do, the Federal Government is entering into direct and ruinous competition with physicians licensed to practice medicine in the various States composing the Federation.

3. The use of Veterans Administration Hospitals to hospitalize other than veterans is morally, and perhaps legally, a wrong to the Government, to all tax-payers and causes the Government to enter into the same type of competition with physicians as referred to in paragraph 2.

We recognize while uttering the above that mistakes have been made in building some veterans hospitals so large as to provide several times the need of the veterans now or

ever in that section. Such hospitals should be disposed of by the Government, a moderate capital loss being more sensible than a huge loss from caring for those who will be better citizens if they care for themselves.

4. After the same manner the Government in the excessive inclusion of other citizens among those eligible for admission, is entering into competition with many hospitals organized and maintained by the tax-payers of the county, town, city or village, or organized and maintained by benefactors, or by the action and co-operation of generous citizens. In this way the Government is abolishing the usefulness of institutions set up by citizens who again have to pay taxes to support the veterans hospitals. Is the Government to succeed if it unjustly abolishes the usefulness of citizens or institutions who should be supporting it? Will the citizenry long accept excessive repeated taxation for the same item?

We hope that all of our members will use all of the influence which they can possibly summon to promote the abolition of these nefarious practices which are inimical to the interests of millions of high type citizens. Plans

should be made to close veterans hospitals as rapidly as is possible. None should be necessary after 25 to 30 years. In all probability the number of beds can at present be justly reduced to one eighth of present capacity and still serve the disabled veterans well.

The most important consideration in connection with this question is the growing policy of Government pauperization of heretofore self respecting and self-supporting people. A taste of free hospitalization, free coal, free light, free provisions, rapidly deposes the sense of responsibility in the majority of minds. The chief concern of the individual thus affected is not how to contribute to his day and civilization all he possibly can, but how he can get as much as he possibly can for nothing, without work. The development of this spirit means either socialism or communism.

We exhort all our members to write their opinions in this important matter to our Senators and Representatives and to just as many other Senators and Representatives as they see fit.

Committee on Economics.

LIVINGSTON COUNTY

The annual meeting of the Livingston County Medical Society was held at the Big Tree Inn, at Geneseo, N. Y., on Tuesday, October 4, 1932, at 7 P.M.

After a turkey dinner, the meeting was called to order by the Vice-President, G. E. Murphy. The minutes of the last meeting were read and approved. The Secretary-Treasurer's report was read. Dr. L. A. Damon acted as secretary in the absence of Dr. G. M. Doolittle.

The following officers were elected for the coming year:

President, Dr. G. E. Murphy, Mt. Morris, N. Y.

Vice-President, Dr. L. A. Damon, Sonyea, N. Y.

Secretary-Treasurer, Dr. G. M. Doolittle, Sonyea, N. Y.

Delegate to State Society, Dr. W. T. Shanahan, Sonyea, N. Y.

Alternate Delegate, Dr. G. E. Murphy, Mt. Morris, N. Y.

Censors, Drs. Preston, Burt, Newton, Shanahan, and Lauderdale.

The scientific program consisted of a paper by Dr. G. E. Murphy of Mt. Morris, on "Infections of the Hand." Dr. Murphy ably covered the subject of infections, including felon, synovitis and bursal infections, giving many differential diagnostic points and outlining various methods of treatment. The paper was discussed by Doctors Smith, Driesbach, Martin, Bowen and Klostermeyer.

Dr. B. R. Wakeman of Hornell, N. Y., outlined the program of the State Department of Health in regard to venereal diseases. He stated that the County Board of Supervisors was considering establishing a venereal disease clinic in Livingston County and suggested that the society be prepared to furnish a list of physicians available for such work.

GEORGE M. DOOLITTLE, *Secretary*.

JEFFERSON COUNTY

The annual meeting of the Medical Society of Jefferson County was held on Thursday evening, November the tenth, at the Jefferson County Sanatorium, Watertown, N. Y. The members and visitors were guests of Dr. James C. Walsh, the superintendent, at a turkey dinner. The following officers were elected for the year:

President, Dr. W. S. Atkinson.
Vice-President, Dr. E. E. Babcock.
Treasurer, Dr. W. F. Smith.
Secretary, Dr. C. A. Prudhon.
Censors: Dr. D. G. Gregor, Chairman; Dr. F. J. Lawler, Dr. G. F. Bock, Dr. F. R. Calkins, Dr. Harlow Ralph.
Delegate to State Society, Dr. M. M. Gardner.
Alternate, Dr. J. E. McAskill.
Delegate to District Branch, Dr. J. C. Walsh.

Dr. Edmond Suss, Philadelphia, N. Y., was elected to membership.

Dr. James C. Walsh presided at the scientific session, whose program he had prepared.

The first paper was on "The Surgical Treatment of Pulmonary Tuberculosis from the Physician's Standpoint," by Dr. Edward N. Packhard, Saranac Lake.

"The Role of Surgery in the Treatment of Pulmonary Tuberculosis" was the subject of the second paper, by Dr. Edward S. Welles of Saranac Lake.

An interesting discussion was led by Dr. LeRoy Hollis, superintendent of the Oswego County Sanatorium, and Dr. J. R. Patton, superintendent of the St. Lawrence County Sanatorium.

CHARLES A. PRUDHON, *Secretary*.

DUTCHESS-PUTNAM COUNTY

A regular meeting of the Dutchess-Putnam Medical Society was held on Wednesday, November 9, 1932, at 8.55 P.M. at St. Francis Hospital, Poughkeepsie, N. Y., with the president, Dr. W. A. Krieger in the Chair, and thirty members present.

The following were elected to membership:

Martin J. Poppo, Rhinebeck, N. Y.; Helen P. Langner, Vassar College, Poughkeepsie, N. Y. (transferred from the Medical Society County of New York); Lewis Saiken, Pawling, N. Y. (transferred from Medical Society County of New York).

The following nominating committee was appointed to report at the December meeting: Drs. Sobel, Breed and Rivenburgh,

The scientific program was as follows:

"Encephalography and Ventriculography—Their uses in general medicine and the specialties." Lantern slides and X-ray pictures; by Dr. Rubin A. Gerber, Assistant Professor of Neurology, Post-Graduate Hospital, New York.

The meeting adjourned at 10.30 P.M. for refreshments.

Present: Drs. Borst, Buckley, Benson, Carpenter, Davison, Deutch, Deyo, Gerlacker, Harron, James, Krieger, Leonidoff, Marks, McGrath, Neighbors, Peuse, Rosenberg, Rivenburgh, Rosenthal, Sobel, Smith, Toomey, Thomson, Voorhees, and Warner.

H. P. CARPENTER, *Secretary*.

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall on November 16, 1932, was called to order at 9 p.m. with the President, Dr. Klein, in the Chair.

The following doctors were elected members: Drs. William Belinkin, Joseph H. Crawley, Frederick Gordon, Louis H. Klinger, Jacob M. Leavitt, Hugh A. Riley, and Murray Sheftman.

Dr. L. A. Friedman, Chairman of the Committee on Public Health, reported on the progress being made in the work of the Committee relative to the examinations of high school students under the auspices of the County Society. He emphasized that the matter has finally been brought to a successful conclusion.

Dr. George E. Milani was nominated and elected an alternate delegate to the State Society.

The scientific program consisted of a paper on "Nephritis and Nephrosis: Etiology, Treatment and Prevention" by Dr. Albert A. Epstein.

The paper was discussed by Drs. Samuel Gitlow, Edward P. Flood, Emil Koffler, Joseph Golomb, and Isidore H. Goldberger.

At the conclusion of the scientific session, Dr. Klein referred to the Gibson emergency unemployment relief committee drive, and asked the members to assist in making the drive on the part of the doctors of the Bronx a success.

The President appealed for the cooperation of the members in the matter of the beefsteak dinner, to be held on January 25th, for the benefit of the relief fund of our society.

I. J. LANDSMAN, *Secretary*.

THE DAILY PRESS

COST OF MEDICAL CARE

The report of the Committee on the Costs of Medical Care, which was released at a meeting on November 29, in the New York Academy of Medicine, has received front page publicity in the New York Metropolitan dailies, and many columns of popular explanation in the inside sheets, especially the Sunday editions. In addition the papers have frequently carried editorial comments, which generally support the principle of an extension of a further development of individual practice by family doctors. The New York *Times* of December 1 says editorially:

"At whatever costs, both the majority and the minority reports of the Committee on Medical Costs agree, the general practitioner should be restored to his place—the central place—in medical practice, and the personal relations between patient and practitioner should be maintained. This is of first importance. It must be the *religio medici*. But there must be a group organization of some sort in order to bring such professional service within the reach of every man, woman and child. A society that does not recognize the obligation to make its skills in protecting and saving human life available for all has not reached or even approached its ideal. How that is to be done there may be and is disagreement.

"It is difficult to think of any boon to mankind that would be more welcome to the millions of heads of families than the guarantee of competent medical attendance within the range of modest incomes. With this should be given not only the honor which from earliest civilization has been accorded the physician, but also a deserved tangible reward, for soon or late we all have need of him. Then, as Achilles said of Machaon, the Homeric doctor, 'he is worth a host of us.'"

An editorial in the New York *Herald Tribune* of December 4 opposes the principle of mass insurance advocated in the majority report of the Committee, and supports the minority report in the following editorial:

"The recommendations of Dr. Ray Lyman Wilbur's committee for the partial socialization of medicine are certain to inspire more confusion and doubt than confidence. The promise that is extended of the elimination of incompetents, exorbitant charges by special-

ists, 'fee splitting' and the further promise of making medical attention available to other than the very rich and the very poor in return for reasonable insurance charges will not dispel the layman's natural repugnance to the idea of making something like a fireman or a policeman of the man with whom his family has its most intimate relations outside the family circle.

"The theory of the contract system is that when the family man voluntarily agrees to pay a doctor or group a small sum annually for treatment, he and his dependents go to the physician with symptoms instead of advanced ailments. Logically this should result in more preventive work, less serious illness, better fixed incomes for doctors and less cost per capita among all classes. So it has indeed worked out in isolated communities, here and abroad. But, as the minority report shows, no such voluntary system has gone far in Europe without becoming compulsory; while in this country it has usually bred 'loss of personal relationship of patient and physician, demoralization of the professions' and numerous abuses. Such testimony does not, however, stand in the way of an experiment which the Wilbur committee and its supporters can make anywhere by getting financial support for a medical center and popular patronage, and by proving then that the system can pay its way without sovietizing the profession.

"The imposition of such a system on the public by propaganda and legislative action cannot be too strongly discounted. There is no use saying that the Wilbur committee's system would not go this far, for bureaucracies are never satisfied with small degrees of control over individual liberties. The time to check the growth of such ideas is at their inception, which in this case is the immediate present, and we sincerely hope that the orthodox medical bodies will succeed in doing so."

The New York *Herald Tribune* of December 6 refers to the report of the Commission on Medical Education, of which President Lowell of Harvard was chairman, and says:

"The grounds on which the Lowell Commission rejects the thought of socialized medicine are that voluntary medical insurance systems tend to become compulsory and these result in mediocre professional service.

RESEARCH AND RELIEF

In these days of depression, when the emphasis is placed on immediate relief, it is encouraging to read of the progress that has been achieved through scientific research. The *New York Times* of October 31 has the following editorial on the work done by the Rockefeller Foundation:

'The sum of \$18,737,967.90 which the Rockefeller Foundation has appropriated 'toward the advancement of knowledge' would not have gone far in mere relief. It has been spent largely in seeking the causes of physical, social and economic ills in many parts of the globe, and in preparing young men and women of promising qualifications to help in carrying on programs of human benefit in the five fields of its philanthropic interest: public health, medical, social and natural sciences, and the humanities. It undertakes very little research itself, it makes grants to universities and other agencies competent to inquire into the fundamental aspects of things touching human life.

It gave more in 1931 to the social sciences than to any one of the other fields, but has ministered more directly to the well being of the peoples of the earth through the International Health Division. It has made a distinct advance in the campaign against yellow fever. It is still fighting malaria, hookworm and other diseases, with encouraging returns from every front. Forty seven countries throughout the world were given as

assistance in their laboratory and field work, and thirty seven of our own States were likewise aided. Even in the present depression, it is stated public health work throughout the world is being maintained.'

'The Foundation also gave subventions to studies of the earth itself and its heavens—the sky-roofed habitation of man, perhaps the only spiritual tenant of the universe. On the one hand it has made liberal grants for inquiring into the depths of the oceans and fresh-water lakes, to learn what further contributions they can make to man's nourishment; and on the other has set watch upon the aurora. It has not only given support to the Institute of Pacific Relations in the hope of bringing about 'a truer and more sympathetic understanding of the problems of the Pacific,' but has brought to light again the sinanthropic dweller in prehistoric Peking.

Two gifts that show the 'illocality' and diversity of its interest are: one of more than a million to McGill University for the maintenance of the Neurological Institute; the other of more than two millions to the famous Bodleian Library in Oxford University, thus lengthening its life by as many centuries as it has already endured, thanks to Sir Christopher Wren, and giving scholars through generations leave to sit 'in the lap of eternity.'

THE MISSING LINK

The *New York Herald Tribune* of November 14, commenting editorially on the death of Professor William Patten of Dartmouth College, refers to Dr. Patten's studies in the remote ancestry of man and says:

'The missing links in the evolutionary story are not in the traditional location between man and the apes, but enormously farther back. Man's animal ancestry can be traced with an approach to perfection back as far as the primitive fish, which means the Cambrian Period, or something like 500,000,000 years. Then comes the bridge, less gap to earlier forms, no one of which can be identified certainly as man's ancestor. That this gap must have been bridged somehow is indubitable. There are too many similarities between the earlier creatures and the later ones to be considered accidental. The mystery is by what path the gap was crossed, which of the earlier creatures was nature's jumping off point for the leap to the backbone and further evolution. Three earlier creatures are candidates for this honor. One might be called a shrimp. Another is a baby sea cucumber. The third is a worm.

Professor Patten's candidate was the shrimp, also related to the modern scorpions and probably ancestral to the insects. His evidences for this were similarities between the nervous system, the mouth parts and other features of these ancient sea shrimps and of certain equally ancient fish indubitably provided with backbones. The details are technical, but experts, admitting the skill of Professor Patten's argument, remain prevailing among the skeptics.

'Advocates of the worm ancestor for the vertebrates follow the late Professor T. C. Chamberlin in imagining an effect of the running water of streams in stiffening the backs of previously spineless worms that needed to ascend them—a plausible theory, but lacking direct evidence either from fossils or otherwise.

The third candidate the baby sea cucumber has more facts behind its claims since there still exist a few primitive vertebrates whose babies closely resemble the sea cucumber infants imagined to represent the joint ancestral forms. Yet this theory, too, lacks confirmation from actual fossils. It is any candidate's race in the search for man's ancestor.'

BOOK REVIEWS

HUMAN STERILIZATION. By J. H. LANDMAN, Ph.D., J.D., J.S.D. Quarto of 341 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$4.00.

The interest aroused in any issue becomes more fascinating when it faces strong opposition. That there is already a liberal Catholic movement, independent of the Roman Catholic Church, which has recently permitted human sterilization for therapeutic and even for eugenic purposes, is especially significant.

Eugenics is still in its infancy even though 27 States of our Union have introduced sexual sterilization legislation and over 12,000 people have already been sterilized. When one considers that the number of morons and imbeciles and criminals run into the many thousands we can readily understand that very little has as yet been accomplished in this field.

The law offers us a weapon to deal with abnormal society. That prevention of the spread of undesirables is quite as important is unfortunately not appreciated by our lawmakers.

To convince the reader of the need for sterilization, the author offers statistics showing the actual increase of mentally incompetent year by year. There are chapters dealing with the laws and court decisions, the sociology, psychology, heredity and eugenics of mental ailments; also the surgery of sexual sterilization. And, finally, there is an extensive bibliography on this increasingly important problem.

EMANUEL KRIMSKY.

MATERIA MEDICA PHARMACOLOGY THERAPEUTICS AND PRESCRIPTION WRITING. By WALTER A. BASTEDO, Ph.G., M.D., Sc.D., F.A.C.P. Third edition. Octavo of 739 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$6.50.

As in previous revisions, the author in this fourth edition presents the view that experimental data obtained from normal health animals should not be applied in the treatment of disease in man without first having their practical value tested under controlled conditions. He implies that the information derived from this source should not be discussed in such detail as to necessitate curbing the space allotted to those established facts, both laboratory and clinical, which are of more importance to the practicing physician.

The text has been extensively revised and brought up-to-date, new articles having been added on suprarenal, cortex, ephedrine, quinidine, the barbiturates, insulin, the mercury diuretics and a number of other drugs. The discussion on digitalis has been enlarged, the subject matter, both experimental and clinical, being presented in a manner readily understood by the medical student and physician. On the other hand, such drugs as camphor and strychnine are given too much space in comparison with their relative importance. The plates depicting skin lesions of drug idiosyncrasy, the tables and the charts are of especial interest.

As a text-book of materia medica and therapeutics, rather than one of pharmacology, is this fourth edition recommended.

DAVID I. ABRAMSON.

BAILEY'S TEXT-BOOK OF HISTOLOGY. Eighth edition. Revised and rewritten by ADOLPH ELWYN, A.M., and OLIVER S. STRONG, A.M. and Ph.D. Octavo of 746 pages, illustrated. Baltimore, William Wood & Company, 1932. Cloth, \$5.50.

The authors of the eighth edition of Bailey's Text-Book on Histology have made it an excellent reference book. It serves as an aid to students because of its

simplicity, clarity, arrangement of the subject matter, and the numerous illustrations.

The chapters on the organs are thoroughly modernized and more extensively illustrated with microphotographs.

Because of the authors' personal efforts in the field of neurology, the chapters on nerve tissues, nervous system, and sense organs are very complete and commendable. They have incorporated many of their own laboratory findings which extend over many years of conscientious efforts.

A chapter of special interest in this volume is devoted to the "living cell." It is believed that the subject matter included in this additional feature will eventually help to bridge the gap between histology and pathology.

NATHAN REIBSTEIN.

PAIN IN THE PLEURA PERICARDIUM AND PERITONEUM. A Clinical Study. By JOSEPH A. CAPPS, M.D., Octavo of 99 pages, illustrated. New York, The Macmillan Company, 1932. Cloth, \$3.00.

This volume presents a clinical study in which physiological methods are applied to human beings. It is a study of pain reflexes of the pleura, diaphragm, pericardium, and peritoneum. While in a general way clinicians were familiar with these reflex pains they had not been definitely established experimentally. Animals do not make good subjects for experiments on pain. Based on an accidental contact of a trochar with the diaphragm during a pleural paracentesis which produced referred pain to the neck these clinicians were stimulated to further investigations by a method of their own which has definitely established these pain reflexes. This is another contribution by clinicians to scientific medicine.

HENRY JOACHIM.

MINOR SURGERY OF THE URINARY TRACT. By HERMAN C. BUMPUS, JR., Ph.B., M.D., M.S. in Urology, F.A.C.S. Octavo of 124 pages, illustrated. Philadelphia, W. B. Saunders Company, 1932. Cloth, \$3.00.

This little volume covers in a concise and extremely practical manner the subject presented. There are chapters on anesthesia, urethral caruncle, stricture of the urethra, cystoscopic resection of the bladder neck, vesical calculi, tumors of the bladder, bladder infections, ureter calculi and post-operative care.

Dr. Bumpus speaks with the authority of an extensive experience and has packed a tremendous amount of valuable information and advice in a small volume.

This book should be in the library of every practicing urologist, particularly those in the younger group.

N. P. R.

ESSENTIALS OF PEDIATRIC NURSING. By RUTH ALICE PERKINS, R.N., B.S. Second edition, revised and enlarged. Octavo of 467 pages, illustrated. Philadelphia, F. A. Davis Company, 1932.

A small volume of a time subject. The subject matter is treated in a manner that speaks for extensive nursing experience on the part of its author. Best are the chapters on Hygiene of Babyhood and of the Older Child. Nutrition is treated very ably and interestingly.

Some of the therapeutics and differential diagnoses, notably on intussusception and that of croup, were best omitted from a book such as this—one cannot do justice to the subject matter. The nurse student might fail to see their importance with devastating consequences to her patients.

HARRY APPEL.

THE ANATOMY OF THE HUMAN ORBIT. By S. ERNEST WHITNALL, M.D. 2nd edition. Octavo of 467 pages, illustrated. New York, Oxford University Press, 1932. Cloth, \$6.25.

To those acquainted with the first edition of Whitnall's *Anatomy*, it hardly seems possible that there would ever be occasion to write a second edition, the first being so thorough and complete. The author has, however, added much valuable material to the original text, thus creating a work which, without doubt, will always maintain a first place among the classics of anatomy. This volume is strongly recommended not only for the ophthalmologist but also for the otorhinologist, the plastic surgeon, the neuro surgeon and the internist. It seems almost a pity that the field which it covers cannot be expressed in the title. Professor Whitnall has covered most completely practically every aspect of the anatomy of the whole head. Its very lucid style and interesting manner of presentation is very evidently but the written form of his own verbal pronouncements. To one who has heard him lecture on a number of occasions, the book vibrates with an animation which one would think impossible in a study dealing with dead tissues. The illustrations are particularly remarkable and a happy selection of drawings and photographs has resulted in an ideal picturization of complicated structures most difficult to visualize. It would seem almost inconceivable how any ophthalmologist could contentedly practice his specialty without constant reference to this wonderful work.

JOHN N. EVANS.

THE HEALING CULTS. By LOUIS S. REED, Ph.D. Octavo of 139 pages. Chicago, The University of Chicago Press, [c.1932]. Cloth, \$2.00. (Publications of the Committee on the Costs of Medical Care: No. 16.)

There are 142,000 licensed and trained physicians in active practice in the United States, and 36,000 other individuals or Cultists who hold themselves out as able to cure disease and treat the sick. The public spends \$125,000,000 annually for the services of Osteopaths, Chiropractors, Naturopaths, Christian Science, and New Thought healers. The United States is essentially the only country which has this problem to contend with.

Each sect was founded by a person who possessed a religious fervor combined with a new conception of disease. Andrew T. Still, who founded Osteopathy, was an unpolished and eccentric frontiersman and farmer. He tried out his theories on the Shawnee Indians of Kansas, convinced himself that God had a particular visitation. D. D. Palmer, a grocer whose attention was attracted by the wonderful power of some magnetic healers. He found his own body to be surcharged with animal magnetism, went about practicing, and after many cures, which seemed miraculous, proceeded to discover Chiropractic. Naturopathy is essentially an outgrowth of Chiropractic. Christian Science and New Thought both owe their origin to a magnetic healer, one "Doctor" Phineas Parkhurst Quimby of Portland, Maine, who was convinced that his was the very method used by Christ in performing His miracles of healing. Quimby cured Mrs. Mary Baker Eddy, who had been an invalid for forty years. Based upon his theories she founded Christian Science, wrote her book, *Science and Health*, which those of her persuasion consider inspired, and spread the gospel of religion and truth versus disease and error to the world. Her maxims are examples of complete radical idealism.

So much for what the cults are. Economically, they extract \$125,000,000 a year from those of the public who are evidently dissatisfied with their experience with "regular physicians." The Medical Profession is somewhat to blame for this state of affairs. Osteopathy and Chiropractic could have been "nipped in the bud" if

medical men had embraced and emphasized the value of massage; but this modality never came into its own, as far as the profession is concerned, until a decade or so ago—almost eighty years after the advent of Osteopathy Still, and twenty-five years after D. D. Palmer and his son B. J. showed what salesmanship could make of an idea. *Divorce the philosophical and religious side of Christian Science Healing from the argument, and it is clearly seen that our neurologists fell down in their opportunity to heal and care for functional nervous disorders in an intimate enough manner to convince thousands of nervous patients of the soundness of their theories.* Even within our immediate memory, the standing of a doctor of medicine practicing psychology was not to be mentioned in the same breath with his neurological colleague, in whose soul reposed a sincerity of purpose founded on scientific, concrete medical knowledge, rather than on abstract, metaphysical theories.

From this report your reviewer is of the impression that the profession owes itself a rebuke for fostering a "holier than thou" attitude towards these various movements. We have neglected to realize that the atmosphere of American life is charged with a spirit of optimism, hope, progress, success, and prosperity, which cannot be suppressed by pessimism, ultra-conservatism, watchful waiting, and indifference.

We are not advancing the argument that modern medicine should become fadistic, but we do say that such movements as foster the tolerance of 36,000 irregular practitioners who collect \$125,000,000 a year for their services from the same public to which we cater, must have some good features worthy of adaptation. The text of this report proves that we gradually absorb the good features of these cults, but it is by the slowest kind of osmosis. Barnum was right—the American people like to be fooled. Organized medicine must protect its public from cultists with the same vigor that it guards the community against contagious diseases. This protection should, if we are to profit by past performances, embrace an active interest in every new movement of this kind. After a careful, unbiased estimation of the new cult, we should hasten to our public with the facts. If the facts show that the movement has some therapeutic merit, accept its good points at the time, not eighty years afterwards.

D. E. McKENNA.

QUANTITATIVE CLINICAL CHEMISTRY. By JOHN P. PETERS, M.D., M.A., and DONALD D. VAN SLYKE, Ph.D., Sc.D. Vol. 2, *Methods*. Octavo of 957 pages, illustrated. Baltimore, Williams & Wilkins Company, 1932. Cloth, \$10.00.

The authors have written a fitting supplement to their masterful first volume on interpretations. This book presents methods for the determination of those substances, found in the body and its excreta, which are of importance for clinical medicine. Thus most of the methods used in the clinical and research laboratory are included. Wherever available the authors give gravimetric, titrimetric, colorimetric and gasometric methods for the quantitative analysis of bio-chemical substances.

The book opens with two extensive chapters on technique in the laboratory describing the important basic requirements of making accurate estimations and producing reliable results. Then follow chapters describing recognized methods for estimating organic and inorganic constituents of the body. There are also chapters on the analysis of gas mixtures, respiratory metabolism, lung volume, blood volume and acid base metabolism.

Each chapter opens with a critical analysis of the principles employed in the analyses, and closes with a bibliography of the original papers describing the methods. It is thus more than a manual. Every biochemical laboratory should find the two volumes invaluable additions to its library.

WILLIAM S. COLLENS,

OUR NEIGHBORS

CHIROPRACTIC IN MASSACHUSETTS

The New England Journal of Medicine during the Fall has frequently printed notices of an initiative ballot by the voters of Massachusetts on the subject of legalizing the practice of chiropractic in that state. (See N. Y. State Jour. of Med., Nov. 15, 1932, page 1338.) The Massachusetts State Legislature has consistently voted against the legalization of the cult; and so the chiropractors resorted to the initiative petition to be submitted to the voters on Election day. The State Medical Society conducted an aggressive campaign of educating the voters, with the following result, as announced editorially in the New England Journal of Medicine of November 17, 1932:

"The petition of the chiropractors of Massachusetts for endorsement of this cult by the appointment of a separate board of registration of their practitioners, as it appeared on the ballot before the voters of this Commonwealth at the last election, was rejected by a plurality vote of well over one hundred thou-

sand. The result was secured by a united profession which carried on a campaign of instruction reaching to almost all the communities of the state. This shows that organization and enthusiasm is effective when inspired by a purpose to protect the people from definite dangers.

"A campaign of this character requires the expenditure of considerable sums of money which were provided by local groups supplementing appropriations by medical societies.

"The appeal to the voters to vote No was founded on the advantages of the single standard of education and experience required to meet the examinations of the Board of Registration in Medicine and was not a defensive movement by physicians. The more general understanding of the state requirement will strengthen appeals for state recognition of higher standards for registration of all who may wish to assume the responsibilities of caring for illness."

SCIENTIFIC EXHIBIT AT THE INDIANA MEETING

The November issue of the Journal of the Indiana State Medical Association discusses the scientific exhibits at the annual meeting of the State Society in the following editorial:

"Medical meetings come and go and in the main are much alike. The scientific papers, the politics, the visiting with old friends, the smokers and the banquets are much alike from year to year. In recent years, however, there has been a major new development that bids fair to become the most instructive part of the whole session if it is not already that. We refer to the scientific exhibits. As short a time as six years ago the writer prepared one of the first scientific exhibits which has been displayed, in recent years at least, in the Indiana State Medical Association assembly. It was nearly the only one shown that year. This year at Michigan City there must have been thirty or more exhibits and many of them of considerable interest. A careful study of all of them would have taken a half day and would well have repaid the ambitious delegate or member for his trouble.

"We were fortunate at the meeting just past in having a place where the booths could be reached easily. When meetings are held in hotels and the exhibits are housed in hotel

rooms on the mezzanine floor, the attendance at the exhibits is not so good and the persons preparing them are somewhat inclined to wonder whether the attention received has warranted the time and expense that has been taken.

"It is no small matter to prepare something that will be worthwhile. These demonstrations commonly represent far more effort than the presentation of a paper and they are given more attention than a paper. Such being the case we feel that more attention should be given to this phase of the work.

"The exhibits should be described perhaps in this Journal, the author of the description being the exhibitor himself. Not unlikely these descriptions should be published by the Journal a month or so before the meeting so that members might have some idea of the subject matter and be the more able to ask intelligent questions concerning them. Certificates of merit also might be granted by a committee appointed for the purpose of evaluating the displays. The awarding of such certificates adds much interest to the scientific exhibit of the American Medical Association; it makes the hard-working demonstrator feel that his

THE CURRENT INDEX

Editorial Comments

THE NEW YORK STATE JOURNAL OF MEDICINE is the organ of the Medical Society of the State of New York, and is the ordinary source to which a historian would go for a record of its activities and those of its constituent county societies. These records are on subjects as varied and diversified as are the activities of the societies.

The interests of the readers are also diversified, and what deeply interests one member may have no special appeal for another; but an index should contain references to all the items in the Journal.

There are two systems of arranging an index:

1. A continuous alphabetical record of the entire volume.
2. A departmental index.

For five years the Journal has followed the departmental system in making an index, for the following reasons:

1. Each of the eight departments is a unit, and deals with its subjects in a distinctive manner. The scientific department contains original papers on topics relating to the practice of medicine by individual doctors on individual cases. The greater proportion of the papers in this department have been prepared for reading before medical societies and are therefore strictly medical and technical. A separate index of these articles will be comparatively short, and any item may be found readily.

2. A reader nearly always knows the character of an article for which he searches, and will turn to the department in which it would most likely be found.

3. A departmental index indicates the nature of the article. A scientific article may deal with the scientific principles of an individual case of a disease; or it may refer to an administrative method for dealing with the public health phases of a group of persons. For example, an article on how diphtheria antitoxin is made and how it acts belongs in the scientific department; but a description of an administrative method adopted by a county society for giving toxin-antitoxin to a roomful of school children would go naturally in the news department in which the activities of the societies are recorded.

The administrative activities of the medical societies are indexed in one group which includes not only the activities of the official socie-

ties of New York State, but also the societies of other States as recorded in their official State journals. Outside of these State journals and those of county societies, there is only a small amount of literature and records of the public health and administrative activities of the official medical societies. Even the public health journals carry but few references to the State journals. It was for the purpose of abstracting these records and publishing them in available form that the department of "Our Neighbors" was established in the *New York State Journal*. These records are fully indexed, and are listed with the records of the societies of New York State.

The activities of the medical societies of the several States are remarkably similar to those of one another, and anyone wishing to introduce a new public health activity in New York State would do well to consult the index to see what other State societies are doing in the same activity. Since the NEW YORK STATE JOURNAL OF MEDICINE is now indexing those activities for the sixth consecutive year, the amount of information which it carries regarding these activities is greater than that in any other source. An example is that a research worker, seeking all available records on graduate medical education, doubled the number of references when the NEW YORK STATE JOURNAL'S indexes were called to her attention.

Why are the records of the civic activities of the official medical societies ignored? The answer is probably that those activities are in a stage of development, and have not yet reached a stage of standardization; but the time is rapidly approaching when the medical society of every State and county will follow a standard program in activities in public health and civic lines. The medical societies are entering upon civic activities, and are trying new methods whose record is available in only the State journals.

Physicians are observing what the medical societies are undertaking, and are supporting them in surveying present services and outlining new ones adapted to the needs of their own communities. A perusal of the seven pages of the index of the year's activities of the medical societies contained in this Journal will reveal the great and growing extent of the civic activities of the official medical societies of New York and other States.

Relative Values of Carbohydrates

New Findings → Confirm Old Truths

Recent scientific investigations in rats (tabulated at the right) are in accord with many years of clinical observations on babies, as shown by the following excerpts from authoritative medical literature reflecting the consensus of three decades of pediatric experience.

CHART OF CARBOHYDRATE HYDROLYSIS¹

MILK SUGAR GROUP	MALT SUGAR GROUP
Lactose** (Milk Sugar)	Starch
	Amylodextrin***
Dextrose*	Erythro-dextrin***
Galactose*	Achro-dextrin***
	Maltose**
CANE SUGAR GROUP	Dextrose*
Saccharose** (Cane Sugar)	Dextrose*
	Note—The end product of maltose is all dextrose, which means quicker assimilation than end products from other carbohydrates
Dextrose*	Levulose*

*Monosaccharide **Disaccharide ***Polysaccharide
Maltose splits into two molecules of dextrose. Sucrose and lactose split into one molecule of dextrose and one of levulose or galactose respectively. It is no doubt due to the simpler structure of maltose that it is more readily absorbed than other sugars. It must also be considered that after assimilation the levulose of sucrose and the galactose

RELATIVE ASSIMILATION VALUES OF VARIOUS CARBOHYDRATES¹

	Average per 100 gms body weight
1 MALTOSE	1.50
2 DEXTRIN + MALTOSE	1.32
3 Glucose + dextrin	1.32
4 Glucose + sucrose	1.32
5 Glucose...	1.04
6 Sucrose + maltose	0.98
7 Fructose + glucose	0.98
8 Sucrose + dextrin	0.76
9 Sucrose.....	0.76
10 Fructose	0.5
11 Glucose + lactose	0.26
12 Lactose -	0.16
13 Galactose	0.1

These authors have also stated: Maltose fructose glucose starch and dextrin feed infants more value than galactose mannose arabinose xylose lactose sucrose and glycogen.

RATE OF SUGAR ABSORPTION IN NEWBORN²

³Morse J L & Talbot F B *Boston Med & Surg J* 159 852.

MALTOSE OR LACTOSE IN INFANT FEEDING³

amount it is necessary to add carbohydrates to some form. Admitting that lactose is the sugar assimilated in human milk it does not follow that it is the sugar best tolerated in another medium, such as cow's milk. It is generally believed that lactose is more laxative than sucrose—that it must be fed with a certain amount of caution as fermentative upsets are likely to follow if amounts approximating that found in human milk are fed. There is cause for disagreement among clinicians as to it is important to consider the other food elements, i.e. the amounts of fat and protein fed as well as the medium in which they are fed. For example, when lactic acid milk is used more added carbohydrate seems to be tolerated than when sweet milk mixtures are fed. Sucrose has the advantage of being much cheaper and is always available. Evidence has not been presented that it should

not be used in infant feeding. With its general use in large infant welfare clinics where supervision is a matter of routine there is less to be said against it as far as clinical results are concerned. The complaint that it is too sweet is not often encountered when the usual amounts are fed. The dextrin maltose preparations possess certain advantages. When they are added to cow's milk mixtures, we have a combination of three forms of carbohydrates: lactose, dextrin and maltose, all having different reactions in the intestinal tract and different absorption rates. Because of the relatively slower conversion of dextrin to maltose and then to dextrose fermentative processes are less likely to develop. Those preparations containing relatively more maltose are more laxative than those containing a higher percentage of dextrin (unless alkali salts such as potassium salts are added). It is common experience clinically that larger amounts of dextrin maltose preparations may be fed as compared with the simple sugars. Obviously, when there is a lessened sugar tolerance such as occurs in many digestive disturbances dextrin maltose compounds may be used to advantage. ⁴Queries and Minor Notes *J A M A*, 88 266

PHYLICIN

Theophylline-calcium salicylate

In Cardiac Disease

A new theophylline salt for oral medication. A well tolerated diuretic and myocardial stimulant.

USUAL DOSE: 4 grains
(or 1 tablet) two to four
times a day.

Literature and
samples upon request.

BILHUBER-KNOLL CORP., Jersey City, N. J.

For Sound Bones and Teeth

Maltcao is a valuable adjunct to the daily diet because it contains a liberal quantity of calcium and phosphates, as well as iron. It supplies these salts so essential for proper bone and tooth structure and development in a food drink with a delicious chocolate taste. So far as is known, Maltcao is the only chocolate food drink that contains these added organic salts.

8 oz. sample can to physicians on request
Merckens Chocolate Co., Inc., Buffalo, N. Y.

Maltcao
BUILDS FOR THE YEARS AHEAD

(Continued from page 1442)

efforts are appreciated; and it calls the attention of the members of the display.

"The physicians of Indiana may well take pride in the fact that scientific exhibiting largely had its origin in the efforts of Dr. Frank B. Wynn, of Indianapolis. It was he who in the late nineties took pathological specimens to the annual sessions of the American Medical Association. From this small beginning has grown the great exhibit that would take days even to observe in a careful way, and might serve as a basis of weeks of study if one had the time and the exhibits were kept up so long."

MALPRACTICE IN NEBRASKA

The medical malpractice situation in Nebraska was described briefly in this Journal of November 1, page 1281. A further discussion is found in the November number of the *Nebraska State Medical Journal*, as follows:

"August 30, 1932, Dr. R. B. Adams, secretary of the Nebraska State Medical Association, received official notification that the Group Policy, carried by the State Medical Association with the United States Fidelity & Guaranty Company of Baltimore, would be cancelled October 1st.

"However, the company was prevailed upon to re-consider this question, and they later decided to continue these policies in force until they had expired. A few physicians, who had had previous law-suits or threats, had their policies cancelled or the company refused to renew their policies. Other insurance companies, which formerly wrote this type of insurance, have discontinued writing it. The Medical Protective Company, who formerly had a full time agent in this part of the country, has discontinued the agency. As a result of this action, some men are finding it difficult or impossible to obtain insurance at this time. Those who may obtain it, do so at an increase in premium of 25% to 200% over the price paid for the former Group Policy.

"It would seem that we are now reaping the reward of some of our former indiscretions, namely, being too ready to criticize the treatment or result of treatment by another physician; failure to disabuse the mind of the disgruntled patient of another physician when opportunity affords; or what is sometimes done, the patient is actually encouraged to believe that his former treatment was improper.

"We now find ourselves confronted with the highest cost of malpractice insurance of any state in the Union, and some of our members finding it difficult or impossible to obtain insurance. During the term of the Group Policy, the rate charged was reasonable and yet was 25% higher than some other states carrying a similar policy. Now it has been increased 25% to 200% by this insurance company, and the general atti-

(Continued on page 1461—adv. xiii)

(Continued from page 1460—adv. xii)

tude would appear to be that they are not eager for this class of business.

"This increase in rate will no doubt cause many to drop their insurance protection. This, we believe, to be unwise, and yet we are convinced that the fact the doctor is insured, makes it more profitable for both the designing patient and the unscrupulous lawyer, who would institute an action of this kind. Since a decision was handed down by the Nebraska Supreme Court, November, 1926, to the effect that it was proper to ask the defendant doctor if he carried insurance, there have been more suits for malpractice than in all our previous history. I have not known of a single case coming to trial in the past five or six years, where the physician carried no insurance. This is not advanced as an argument against insurance; however, the fact that he carries insurance increases his liability of being sued, cannot be denied.

"Several times during the past few weeks I have heard physicians make the statement that 'The economic stress of the past few years has rendered them execution proof, and they expected to remain so,' thereby practically precluding the possibility of a malpractice law-suit. This method may be one solution.

"Another solution would be to secure some legislative enactment declaring the question of insurance to be no point of issue in the case. I am informed on good authority that such legislation would be constitutional and in all probability could be enacted.

"Until every physician awakens to a realization that he, too, is just human, and as such should be more tolerant of the alleged acts of his brother physician, so long as we are given to make disparaging remarks about the other fellow and his work, and until every physician has learned that to foster or aid and abet in any way a malpractice suit against another is only inviting trouble for himself in the future; then, and not until then, will this problem be solved."

GROUP MEDICAL CARE IN NORTH CAROLINA

A concise description of a group-purchase system of medical care in Roanoke Rapids, an industrial town of 10,000 people, is contained in the November issue of the *Nebraska State Medical Journal*, which quotes from a report made by the Committee on the Costs of Medical Care, and says:

"The report describes the organized medical service in Roanoke Rapids which furnishes medical care to two population groups of approximately the same size: one group through a plan involving fixed periodic payments, by the participants; the second group, through the conventional fee-for-service system of payment.

(Continued on page 1462—adv. xiv)

MILK

has almost TWICE the food-energy value when Cocomalt is added

MORE AND MORE physicians are using Cocomalt in milk for high-calory feeding cases—for malnourished children—for convalescents—for expectant and nursing mothers.

Milk alone is not always palatable to those who need it most. *Cocomalt in milk*, however, is delicious, tempting—a real treat not only to children but to your grown-up patients as well.

Prepared according to simple label directions, Cocomalt adds 110 extra calories to a glass of milk—increasing its food-energy value more than 70%. Thus every glass of Cocomalt a patient drinks has the nourishment (food-energy) of almost two glasses of plain milk.

What laboratory analysis shows

Cocomalt, prepared as directed, increases the protein content of milk 45%, the carbohydrate content 18 1/2%, the mineral content (calcium and phosphorus) 48%. Each ounce of Cocomalt—the amount used in mixing one glass or cup—contains not less than 30 Steenbock (300 ADMA) units of Vitamin D.

Cocomalt comes in powder form, easy to mix with milk—hot or cold. At grocers and drug stores in 1/2-lb. and 1-lb. cans. Also in 5-lb. can for hospital use, at a special price.

FREE to physicians

For a trial-size can of Cocomalt free, just mail coupon with your name and address.

CHILDREN
need the extra calcium, phosphorus and Sunshine Vitamin D which Cocomalt provides.

CONVALESCENTS
enjoy Cocomalt. It provides hyper-nutrition without digestive strain.

Cocomalt is accepted by the Committee on Foods of the American Medical Association. That is your guarantee of its trustworthiness. Cocomalt is also licensed by the Wisconsin Alumni Research Foundation under Steenbock patent.

Cocomalt

Cocomalt is a scientific food concentrate of sucrose, skimmed milk, selected cocoa, malt extract, vanilla flavoring, and added Sunshine Vitamin D.

ADDS 70% MORE NOURISHMENT (FOOD-ENERGY) TO MILK
(Prepared according to label directions)

R. B. Davis Co., Dept. T1Y Hoboken, N. J.

You may send me a trial size can of Cocomalt without cost or obligation.

"BUT DOCTOR! CAN'T I EAT ANY . . ."

When the patient begins to despair, you can anticipate trouble in keeping him to the prescribed diet. Have you ever considered how much the recommendation of Knox Sparkling Gelatine can help? Knox permits the patient to enjoy a wide variety of dishes based on a restricted number of foods. It combines with all foods. It is especially valuable for diabetic, reducing, and anemia diets and for liquid and soft feeding.

85-86% protein, Knox Sparkling Gelatine is free from sugar, artificial coloring or flavoring. Thus Knox should be specified to avoid the thoughtless use by the patient of ready-mixed gelatin preparations which contain 70% or more sugar and acid flavoring. On request, the Knox Gelatine Laboratories, 432 Knox Ave., Johnstown, N. Y., will send you facts on Gelatine in the Diet, prepared by accredited authorities, and free diet recipe books to give to patients.

KNOX is the real GELATINE

BE SURE TO SPECIFY KNOX

(Continued from page 1461—adv. xiii)

"Small fixed periodic payments, supplemented by funds from employers which pay the salaries of physicians and visiting nurses, have enabled the first group, mill workers and their dependents, with an average income of \$1,274 per family, to obtain more medical service than is ordinarily obtained by families with incomes of \$10,000 and over, according to the report.

"Through economies resulting from this group-purchase plan, the report brings out the participating mill workers and their families received medical service worth \$129,889, based on prevailing local rates, at an actual cost of \$92,083, a saving of 29 per cent. This computation is based on figures for 1930, the year studied by the authors of the report.

"During the year of the survey, the salaries of five physicians and three visiting nurses were paid by the employers, and each of the workers participating in the plan contributed 25 cents per week, which was deducted from their wages. Through the payments from these two sources, the workers and their families were entitled to medical attention at the doctors' offices or at home, toward accommodations in the local hospital for such periods as might be necessary, and to the services of the visiting nurses, who provided both nursing care and health instruction.

"The group of the population not participating in this system of group-purchase of medical care were served by the same practitioners and the same hospital, but paid for the services they obtained on an individual fee basis.

"Those eligible to medical care under the group-purchase plan received a far greater volume of medical service than did those who paid for their medical care individually. Families eligible under the group-purchase plan used the local hospital five times as frequently as those in the non-participating group; received four times the number of office treatments; three and a half times the number of home treatments; and the benefits of the services of the visiting nurses, who were scarcely called upon by the non-participating group.

"Among the non-participating group, the costs of medical care to the individual varied enormously, while among those benefiting from the group-purchase system the costs were evenly distributed. Two per cent of the non-participating families paid nearly 40 per cent of the total cost of illness in their entire group, while a small number of families, comprising less than five per cent of the group were forced to bear approximately 68 per cent of the total burden of medical costs for their group.

"Although the services are rendered at low cost, physicians were well compensated. The net incomes of the Roanoke Rapids physicians averaged \$8,409 for the year of the study, compared with net incomes of \$5,400 to \$6,300 for physi-

4 New Concentrated Vitamin Products

Vitamin A alone

Name Smaco Caritol Product No. 505

Description. Caritol is a 0.3% solution of carotene in bland oil, providing a safe, palatable and convenient concentration of vitamin A for therapeutic use.

Taste. Entire absence of all fishy taste makes it acceptable to your patients.

Color. Deep red, due to carotene.

Potency. Ten drops contain one thousand International Units of vitamin A.

daily for adults

Package. 15 c.c. dropper top protectively colored bottles, in special cartons to shield it from the light.

Cost. Because of its high potency and the small dosages required, it is an inexpensive source of vitamin A, in spite of the fact that it is the only product containing vitamin A alone.

Indications. For conditions caused by vitamin A deficiency and cured or prevented by adequate vitamin A or carotene dosage.

Vitamin D alone

Name. Smaco Concentrated Vitamin D Product No. 515

Description. This product is Natural Vitamin D, being a highly potent extract of the antirachitic principle of cod liver oil.

Taste. Palatable and free from objectionable taste.

Color. Nearly colorless.

Potency. Ten drops are equal in vitamin D potency to three teaspoons of standard potent cod liver oil.

Dosage. Average prophylactic dose, ten drops daily. Average curative dose, fifteen to thirty drops daily, depending on severity of case.

Package. 5 c.c. and 50 c.c. protectively colored bottles.

Cost. Approximately the same as that current for equivalent vitamin D dosages of plain cod liver oil.

Indications. For the prevention or cure of rickets and spasmophilia, and where ever vitamin D therapy is required, such as tetany and osteomalacia.

Vitamins A and D together

Name. Smaco Vitamins A and D Product No. 525

Description. Smaco Caritol and Smaco Concentrated Vitamin D are combined in this product, providing both vitamins A and D in concentrated form for therapeutic use.

Taste. Palatable and free from objectionable taste.

Color. Red, due to carotene.

Potency. Ten drops are equivalent to one thousand International Units of vitamin A plus the vitamin D potency of three teaspoons of standard potent cod liver oil.

Dosage. Ten drops or more daily, depending upon individual requirements.

Package. 5 c.c. and 50 c.c. protectively colored bottles.

Cost. Approximately the same as current prices for equal dosages of other vitamin concentrates.

Indications. Wherever vitamins A and D are required together in palatable form and small dosage.

Smaco Cod Liver Oil fortified

Name. "Smaco Cod Liver Oil (with Carotene and Concentrated Vitamin D) Product No. 510

Description. A high grade cod liver oil fortified with vitamin A of vegetable origin (carotene) and natural vitamin D described in the second column.

Taste. Although carotene is not a flavoring agent, nevertheless the addition of carotene noticeably improves the flavor.

Color. Deep red, due to carotene it contains.

Potency. One teaspoon is equivalent in vitamin D potency to three teaspoons of standard potent cod liver oil plus 1,000 International Units of vitamin A per teaspoon in addition to the original vitamin A potency of the oil.

Dosage. One teaspoon daily for average individual needing vitamins A and D.

Package. Four ounce protectively colored bottles packaged in special cartons to shield from light.

Cost. Approximately one half as much as the equivalent amounts of vitamins A and D when purchased as plain cod liver oil.

Indications. Wherever a more palatable, concentrated cod liver oil is indicated (Only one third as much is required as plain cod liver oil).

Zucker natural vitamin D

New Vitamin Therapy Possible

Up to this time it has not been possible to prescribe vitamin A alone as in cases where vitamin D is not required or it already supplied by sunshine ultra violet light. It is now possible to regulate the dosage to meet individual requirements.

Smaco Vitamin D is natural vitamin D. It is not an irradiated oil and not a cod liver oil concentrate but rather a highly potent extract of the antirachitic principle of cod liver oil. It is produced for therapeutic use by methods (Zucker Process) developed in the department of Pathology of the College of Physicians and Surgeons of Columbia University.

It now becomes possible with these new Smaco concentrated vitamin products to prescribe vitamin A alone, vitamin D alone, or vitamins A and D together in drop dosages and palatable form thus permitting the physician to prescribe any desired potency of these vitamins and any desired combination.

Smaco C, A and D. This Smaco product, namely—the cost is approximately one half as much as the same vitamin content of plain cod liver oil and only one third the dosage is required.

Information and prices on crystalline Carotene (up to FIVE THOUSAND TIMES the vitamin A potency of cod liver oil) for research purposes furnished upon request.

cians in cities of similar size in other parts of the United States.

"Medical care in that community was highly regarded by the population served and by physicians in the surrounding territory.

"Favorable personal observations were made by both the field workers who made the survey and the medical and surgical authorities consulted. "The desirable personal relation between physician and patient has been scrupulously and completely sustained," the report states."

THE COUNTY SOCIETY IN PENNSYLVANIA

The leading article in the October issue of the *Pennsylvania Medical Journal* is the President's address before the State Society on October 4, 1932, by Dr. Charles Falkowsky, Jr., who discussed county societies as follows:

"The activities of the *medical profession* can be carried on only through medical *organization*. This provides the only proper contact of the profession with the public. The smaller and more cohesive the medical organization seeking this contact, the quicker and more satisfactory will be the result. The means to

this prompt and efficient end is the County Society unit. The State Society can only correlate results which the County Society alone can obtain.

"The medical unit as exemplified by the County Society should be the first to sense the beginning of these efforts at usurpation of our rewards and recompense, and hold itself in readiness to dictate the procedure and form which they may adopt and follow. To allow the layman to start something and then oppose, criticize, and object to it, when his intentions were of the best, comes with poor grace. He was of course both innocent and ignorant of any usurpation of medical privilege and responsibility because the profession had shown no interest. It naturally follows that we receive no cooperation and they simply carry-on without us, usually to our considerable detriment.

"The Committee on Public Relations of the County Society should be the most active, busy, and useful part of the organization. The members should be carefully selected from among those who are willing to sacrifice time and thought, and give action to this work. They must make every endeavor to keep in-

formed as to the various welfare, social, and charitable agencies in their communities, whose basis for existence involves medical aid in any form. They must be properly represented at the various meetings by having representatives on the boards of these agencies, or if that be not practical by having meetings at which the mutual problems can be frankly discussed. These organizations always welcome our suggestion and support and are therefore easily controlled.

"When once started the volume of this work will increase so rapidly that it will become necessary to employ some type of full-time, paid executive to manage the details. He or she, I take it, should be preferably a layman of a considerable degree of education, intelligence, and diplomacy, who could, after a survey of conditions, be able to visualize the requirements of both the public and the doctor in his particular area. He could immediately take under consideration and solve the constant vexations, which will occur, to the best interest of all concerned and with a minimum of friction. In some of our larger county units such men are now employed and the results thus far have been most satisfactory."

PATIENTS OR CASES IN WISCONSIN

The November issue of the *Wisconsin Medical Journal* has an editorial discussion on the personal relation of the doctor to his patient, which is a strong argument against impersonal clinics and state medicine:

"It has always been the glory of clinical teaching in America to see a patient not merely as a 'case' but as a personality, a human being, as well. The best clinical teachers in America, and there have been a host of such men, have always stressed this point of view. To mention only a few there have been Flint, Forstheimer, James Jackson, F. C. Shattuck, Billings, Faville, Weir Mitchell, and among living clinicians are Thayer, Barker, Morris and McCrae. No one has expressed the tradition of American medicine better in this regard in recent years than did Francis Peabody just before his untimely death.

"Osler was the embodiment of this idea in theory and in practice, and his influence has been very great.

"It has always been a shock to our sensibilities to observe some of the great clinicians of Europe at work in the wards of their great hospitals, where seemingly the patient was only a 'case.' I remember well going through the wards with Van Noorden and hearing him

say, 'Send this woman home, we cannot use her any more.' The general attitude seemed cold and scientific with an absence of the human touch we were accustomed to.

"The continental mind is persistent and thorough and will eventually arrive at its goal by pure science if not by intuition and natural feeling.

"It was through the 'Individual psychology' of men like Freud, Jung, and Adler, that the light first began to dawn abroad.

"Now by means of the endocrines an approach is offered which makes the clinician aware that he is dealing not with a simple 'case' but a very complex interacting combination of forces some of them chemical, some of them neurogenic which results in a peculiar physical and mental make-up, the constitution of the individual and his peculiar psyche. In other words the prophet from Vienna comes to America to disclose to us that a patient is a person after all, not simply a 'case.'"

ANNUAL REGISTRATION IN KANSAS

The November issue of the *Journal of the Kansas Medical Society* contains the following editorial on the annual registration of physicians:

"The Kansas Board of Medical Registration and Examination is supported wholly by fees paid by applicants for examination or reciprocity. Funds, therefore, of the board are necessarily limited and only a small sum remains after payment of the expenses of the two meetings.

"Dr. F. J. Engberg, Secretary, Minnesota State Board of Medical Examiners, has recently completed an analysis of laws in regard to the annual registration of physicians in the various states.

"The enactment of an annual registration law with a small fee would be beneficial in many ways:

"The board would have a record of those who were actually licensed to practice in the state.

"A directory could be published and furnish each physician as well as law enforcement agencies. If a physician located in a community reference to the directory would determine if he were licensed to practice his profession.

"The enactment of such a law would not protect the public but the practicing physician as well.

"A fund would be provided for the use of medical board in discovering unlicensed practitioners and enforcing the medical practice act.

"Seventeen states and the Territory of Alaska now require the annual registration of practitioners of the healing art. California was first state to adopt an annual registration effective in 1917; Louisiana in 1918; Connecticut and Idaho in 1919; Iowa in 1924; New York and Pennsylvania in 1926; Nebraska, Oregon and Florida in 1927; Minnesota, Nevada, Wyoming in 1928; Colorado in 1929; North Dakota in 1931; Alaska, Georgia and Texas in 1932.

"Nine states have some form of occupational tax in connection with which an annual registration of physicians is effected. These states: Alabama, California, Delaware, Florida, Georgia, Mississippi, North Carolina, Utah and Virginia. In reality, therefore, twenty-two states have laws requiring physicians to register annually.

"Fees for medical board registration vary from \$1.00 to \$10.00. Occupational taxes range from \$3.00 to \$75.00."

BENEFITS OF THE STATE SOCIETY OF WISCONSIN

Dr. R. H. Jackson, on the President's part of the *Wisconsin Medical Journal* for November, sets forth the accomplishments of the Wisconsin State Society as follows:

"1. Prevented imposition of a wholly unnecessary annual state narcotic tax of \$10

"2. Aided the American Medical Association

(Continued on page 1467—adv. xix)

75%

of **Diabetic Patients**

to secure reduction of the annual federal narcotic tax from \$3 to \$1.

3. Prevented the licensing of lay assistants as independent x-ray experts and prevented the licensing of numerous unqualified and incompetent to treat the sick.

"4. Secured rulings and interpretations on federal and state income tax laws affecting the profession so as to secure proper and justified savings of thousands of dollars annually. Issues an annual review listing this information for the members.

"5. Promoted the establishment of the Medical Library Service at the Medical School of the University. Commercial service of like nature costs upwards of \$10 annually.

"6. Secured an investigator for the State Board of Health to weed out gross forms of quackery. In most states this is, to our minds, unjustly financed by charging physicians an annual registration fee of from \$1 to \$5.

"7. Defeated a bill proposed by compensation insurance companies designed to license industrial nurses to treat the injured except for narcotics and major surgery. Established Standing Orders for Nurses in Insutry since approved by the State Licensing Board and enforced for protection of the injured.

"8. Prevented legislation which would have cost the profession in excess of \$60,000 annually (twice the State Society budget) for tests now made at the State Laboratory of Hygiene."

EX-PRESIDENTS IN COLORADO

The November issue of *Colorado Medicine* has the following editorial on the proposal for continuing the services of the past-presidents of the State Medical Society:

"In reference to the recently proposed amendment to the constitution of our Society to create a Society of Past-presidents, we are interested to note a custom of the Medical Society of the State of New York. Its past-presidents accept appointments as chairmen or members of committees. They thereby continue to give their services to the profession and public. As their years increase, an active rather than a passive professional interest is maintained. The profession profits by a great deal of wisdom and experience which would otherwise be lost.

"Our own contemplated Society of Past-presidents and its representation in the House of Delegates should contribute the same, or even a greater, benefit to the profession in Colorado"

SARATOGA NATURAL MINERAL WATERS

For Acid Correction and Mild Purgation

STATE OWNED AND STATE BOTTLED

SARATOGA mineral waters offer to the profession a selection of naturally carbonated waters possessing valuable alkaline and saline properties. They have been characterized by medical experts as the peers of any waters now to be found in Europe.

Saratoga Geyser is a naturally carbonated alkaline water which has proven to be very beneficial as an aid in the treatment of many acid conditions including: acidosis accompanying gout, rheumatism, neuritis and diabetes, acid dyspepsia and hyperacidity.

Saratoga Hathorn No. 2, mildly purgative, and Saratoga Coesa, mildly laxative, are naturally carbonated saline waters possessing valuable catalytic activity. They have proven beneficial in hyperacidity occurring in cases of acid catarrh of the stomach and atony of the stomach, and in cases of dyspepsia due to mental over-exertion. Because of the sodium chlorid in these waters they are not recommended for patients with nephritis.

WANTED—Position by woman physician. College graduate with fifteen years' office and clinical experience in gynecology, skin diseases and varicose veins. Would like a part-time position in a clinic or hospital or office. New York license and member of Medical Society. Address, Doctor, 143 East 30th St., New York City.

ANNOUNCEMENT

Geo. W. Merck, President of Merck & Co. Inc., recently announced the appointment of Dr. Hans Molitor, of the University of Vienna, to the research staff of the company. Dr. Molitor will assume the direction of research work in pharmacology. In announcing the appointment, Mr. Merck stated:

"The addition of Dr. Hans Molitor, of Vienna, to the staff of Merck & Co. Inc., results from the decision of the management to adopt a policy of intensive research in pure and applied chemistry and allied subjects. To provide adequate facilities for this research work, Merck & Co. Inc., despite the depression, is constructing at Rahway, N. J., at the present time, a research laboratory to cost in excess of \$200,000, which will house a staff of 25 research chemists. Dr. Molitor will take over the supervision of the details of equipping and staffing the laboratory to be devoted to research in pharmacology. See page iv.—*Adv.*

PNEUMONIA

The most recent statistics dealing with pneumonia indicates its successful control in a large number of cases. In 707 cases of pneumonia in which Type I Antipneumococcic Serum was used, the death rate was 18.5% as compared with the untreated cases, in which the death rate was 30% in 553 cases. When serum was used within 72 hours after the onset, the death rate was 10.7% in 177 cases.

Its refinement, as well as its standardization in units, gives the physician adequate information, so that the dosage can be correctly estimated from the results achieved.

Full information will be supplied by the **LEDERLE LABORATORIES**, and communications may be addressed to them at 511 Fifth Avenue, New York City. See page vii.—*Adv.*

COCOMALT USED IN CLINICAL TESTS

Important clinical tests with Cocomalt are being conducted all over

The Westport Sanitarium

WESTPORT, CONN.

An incorporated and licensed institution.

FOR NERVOUS and MENTAL DISEASES

G. H. GEROW, M.D., *Physician in Charge*. Located in an attractive private park on the Boston Post Road. Modern equipment. Adequate personnel and classification.

the country. Whole groups of undernourished children show substantial gains in weight after taking this food-drink regularly. During the recent drought in Arkansas, for example, health officers fed Cocomalt to youngsters for 40 days. At the end of that time, gains of from 4 to 16 pounds were noted (depending largely on age). The average gain for the 40-day period was 8½ pounds—more than a pound a week. Children who missed the Cocomalt clinic or attended irregularly *showed no substantial gain*. Cocomalt is a delicious chocolate flavor food-drink that is almost twice as nourishing as plain milk, adding 110 extra calories to every glass. It contains 30 steenbock (300 ADMA) units of vitamin D per ounce—the quantity recommended for one drink. Samples sent to physicians on request. Write to R. B. Davis Co., Hoboken, N. J. See page xiii.—*Adv.*

WHAT IS MALTCAO?

Maltcao is a scientifically prepared health food consisting of pure sugar, malt, cocoa, partially defatted milk, and liberal quantities of organic phosphates of calcium and iron in the same form as nature produces these salts in grains and vegetables.

"MALTCAO" ANALYSIS:

Moisture	3.03%
Cocoa Butter	4.42%

WARNS AGAINST PROMISCU- OUS DOSING WITH VITAMINS

Ever since 1914, when S.M.A. was developed, the producers of S.M.A.

have been interested in proper appreciation and application of the vitamins, particularly A and D.

Vitamin research has been carried on without fanfare by S.M.A. Corporation since its formation in 1921. As a result, when the fad for irradiated products swept the medical world, the research chemists of S.M.A. Corporation were not satisfied with an artificial source of Vitamin D, and reserved judgment, continuing to use the old, reliable cod liver oil in S.M.A. and to remind the medical profession of this fact. (S.M.A. and Smaco products are not advertised to the public.)

As another result of this research, S.M.A. Corporation was recently able to announce the availability of Primary Vitamin A (Carotene) for therapeutic use at moderate prices.

This is not only a boon to physicians in making possible the prescribing of Vitamin A alone, as well as Carotene for its own virtues, but it will also make possible further research on the properties of Vitamin A. Such an important announcement could not long remain a secret from the press of the country, and about two weeks after the announcement to the medical profession, an interview was printed in which W. O. Frohring, Vice President and Director of Laboratories, was quoted as follows:

"We are offering carotene to the medical profession in three convenient forms,—Crystalline carotene for research purposes; Caritol, which is carotene in bland oil, and cod liver oil with carotene.

"While it is confidently expected that these products will prove to be of immense value to the public, they are not intended for use by the public except under the direction of a physician."—See page xv.—*Adv.*

VICHY CELESTINS

The American Agency of French Vichy, Inc., sole American agents of "Vichy Célestins" water bottled at the Spring at Vichy, France, owned by the French Government. There are other Springs at Vichy also owned by the French Government such as Grande Grille and Hôpital which are imported by these Agents but these are not sent here in as large quantities as the "Vichy Célestins." This Agency also imports the Vichy Salts and Vichy Pastilles which are called Products of Vichy-Etat because they are made from the Salts extracted from the waters of these government-owned Springs. Medical Profession of the United States annually sends many patients for the treatment of diseases of the stomach, liver, etc.—See page v.—*Adv.*
